THIS (THE NINETY-FIRST) VOLUME OF "THE GARDEN"

IS DEDICATED, BY PERMISSION, TO

MR. EDWARD HUDSON.

IT seems fitting that this, the last, volume of THE GARDEN should be dedicated to Mr. Edward Hudson, the Chairman of "Country Life," Limited, who has done so much to bring THE GARDEN to its present high standard of excellence. During the past twenty-five years THE GARDEN has been one of his special hobbies, and during that time he has endeavoured, through the medium of the journal and other publications, to raise the general standard of gardening to a higher level, and to create interest in the gardening art where none previously existed.

It was he who purchased THE GARDEN in 1902 from its founder, Mr. William Robinson, when it became a contemporary of *Country Life*, a journal whose high standing is known throughout the world, and since that date he has been a constant inspiration to all members of the staff of THE GARDEN who have served under him. Through his kindly help and criticism, so willingly given at all times, the staff has benefited greatly in an attempt to conform with his ideas and tastes on how a gardening journal should be produced to serve a useful purpose. At all times he has tried, in practice as well as in theory, to instil a love for the beautiful in gardening, and to avoid that which is harsh and incongruous. His old garden at Sonning, illustrated many times in old volumes of THE GARDEN, showed his ideas carried out extremely well.

Allied to a keen instinct for public taste, he shows a sympathetic understanding of plants and of the men and women who cultivate them. Throughout his life, he has been an enthusiastic gardener, and hence possesses a shrewd knowledge of the problems that beset his *confrères* and how these can best be met. It is this understanding of gardening that has proved of such undoubted service in the production of the gardening publications for which *Country Life* has built up so high a reputation. He loves plants for their beauty of flower and elegance of habit, but it is of the garden, wherein the plants are grouped and combined to create a richness of colour and beauty, associated with an atmosphere of rest, that he shows a true appreciation. He has always endeavoured in the production of gardening books, and in THE GARDEN and elsewhere, to make this the keynote of success in gardening. His axiom is that the garden as a whole should be the chief consideration, and not the plants within it. If the first has been successfully achieved, the second, namely, that of selection and grouping of the plants, must have already been considered.

We feel sure that all our readers will join with us in paying our tribute to Mr. Edward Hudson by dedicating this, the last, volume of THE GARDEN to him as a token of our appreciation and esteem on behalf of his untiring efforts in the publishing world in the interests of English gardening.

INDEX TO ILLUSTRATIONS

Acantholimon venustum, 621
Acanthus, 101
Acer, Japanese, in rock garden, 750
Achillea Kellereri, 451; Perry's White, 106
Achimenes, 112
Agapanthus, in tubs, 281, 777; umbellatus, in tubs, 613
Ageratum Little Blue Cloud, 40
Allanthus glandulosa in a town garden, 765
Allotments, 379
Alpine house in spring, 575
Alpines, planting out, 342
Alstrœmeria, 513
Alyssum, 119; edging of, 274; saxatile citrinum, 352; saxatile on retaining wall, 415; spinosum, 499
Anchusa Italica, 170
Anemone Allenl, 494; apennina, 680; fulgens, 681; hupehensis, 707; japonica, 390, 638
Annuals, border of, 40; seedling, 204; sowing, 204
Anthemis, 85
Antirrhinum asarina, 687
Antirrhinums, in beds, 83
Apple, Brumley's Seedling in a pine wood, 690; canker, 26; cordon, 696; espalier, 90; Lane's Prince Albert, 753, 746; trees attacked by saw-fly, 251; attacked by scab, 237; attacked by woolly aphis, 251; in a town garden, 137; old espalier, 389; young espalier, 696
Aquilegia glandulosa, 435; long-spurred, 364
Arenaria cæspitosa, 635; montana, 313
Armeria cæspitosa, 590; edging of, 67
Artemisia, 64; lactiflora, 344
Arum lily, large, 799
Asperula odorata, 419
Aspidistras, repotting, 167
Asplenium trichomanes, 23
Asters, annual, in border, 200; bedding, 139; china, in tubs, 776
Asters, perennial, border of, 333, 648; division of, 262; King George, 648; Little Boy Blue, 248, 648; Queen Mary, 107; Queen of Colwall, 648; Sonia, 661
Astilbe Arendsii, 175; simplicifolia, 735
Astilbes, border of, 399; in shade, 712; in the herbaceous border, 712
Aubrietias, on low retaining wall, 266; taking cuttings of, 310
Auricula, a show, 308
Azalea mollis, 768; rosæflora, 407
Azaleas, in beds, 8; in formal garden, 104; in semi-shade, 104; repotting greenhouse, 192

Banks, planting shrubs on, 6; rockery, 353, 391, 455, 725; rockery, round tennis court, 388
Baskets, garden, 222; making, 29; making hanging, for ferns, 44
Bay trees, clipped, in tubs, 777
Beans, raising early, 42
Bedding, plants, display of, 593; foliage plants for, 413
Bedding plants, planting out, 278, 366; propagating, 159
Beetroot, lifting, 636
Begonia, Alice Manning, 49; Eunice, 49; Gloire de Lorraine, taking cuttings of, 304; Hilda Langdon, 98; in greenhouse, 98; Venus, 49
Begonias, bed of, 412; in hanging baskets, 49
Berberidopsis corallina, 620
Berberis japonica, 84; prepared cuttings of, 627; stenophylla, 84, 807; stenophylla, inserting cuttings under a bell-glass, 627; stenophylla, taking a cutting of, 620; Unique, 660
Bird-baths, 462; on lawn, 397, 434
Black currant, Laxton's Mite Free, 745
Bog garden, 21
Border, a well staked, 341; annual, 40; by the house wall, 536
Border, herbaceous, 106, 467, 470, 561, 569, 598, 612, 632, 713; curved, 697; double, 227; narrow, 623
Briza maxima, 45
Browallia, 75
Buddleia Colvilei, 609
Bulbs, in beds, 385; in bowls, 194; lifting, 310; mixed border of, 577

Cabbages, how to plant, 504
Cacti, exhibit of, 376
Calceolarias, greenhouse, 351; in a front garden, 531; planting out, 346; planting out for summer bedding, 366
Calendulas, 22
Callistemon speciosus, 425
Campanula, Bellardii, 520; garganica, 312; isophylla, 75; persicifolia, 407; pulla, 312; pyramidalis, 344
Campanulas, Border, 746, 806
Cannas, bed of, in New Zealand park, 584; potting, 129
Canterbury bells, 234, 306, 377
Carnations, at Allwoods' nursery, 739
Carnations, border, Bookham Salmon, 165; Gordon Douglas, 165; lifting layers and potting, 652; Paladin, 165; staking of, 432
Carnations, perpetual, cuttings of, 762; Mrs. A. J. Cobb, 373; where to take cuttings from, 761
Carnations, perpetual border, 38
Carrots, grown in well prepared soil, 125
Caterpillars, surface, 268
Ceanothus thyrsiflorus, 136; Veitchianus, 229
Celery, planting out, 318
Centaurea candidissima, edging of, 412
Cerastium, overgrown, 579; tomentosum, 53; tomentosum, edging of, 386
Chamæpeuce Casabonæ, 649
Cheiranthus Allionii, 234; alpinus, 387
Chelsea Flower Show, gardens at, 347, 348, 349, 387, 388; perennials at, 349, 369, 371
Cherry, double white, 377; Ursula Rivers, 744
Chimonanthus fragrans, 18
Chlorodoxa Luciliæ at Bath's Nursery, 550; Luciliæ in a pot, 589; sardensis, 559
Chrysanthemum Honeysuckle, 28; maximum, 53; maximum in the border, 218; maximum King Edward VII, 407
Chrysanthemums, border, 242; cuttings of, 60, 794; in a tub, 777; in bowls, 12; late-flowering, 686; lifting and potting, 624; potting, 14, 334; staking and tying, 578
Cimicifuga japonica, 808
Cinerarias in greenhouse, 441, 801
Cistus florentinus, 767; Loreti, 595, 767; inserting cuttings in a frame, 627; on a sunny bank, 535; prepared cuttings of, 627; purpureus, 767
Clarkia, 89, 596; in a bowl, 479
Clematis Henryi, 487; montana on a wall, 391; montana rubens, 297; Nellie Moser, 439; on brick wall, 702; vitalba, 328
Clethra alnifolia, 313
Climbers in an Indian garden, 629; on trellised walls, 493
Cloches, 716; protecting seedlings with, 294
Colchicums, 639
Conifers, dwarf, in rock garden, 730
Conservatory, converting, 649
Convolvulus mauritanicus, 608
Corcopsis grandiflora, 47, 85
Cornus Mas, 6
Corydalis nobilis, 25
Cosmea, 24
Cotoneaster divaricata, 660; frigida, 760; horizontalis, 66
Crinums, 577
Crocus Imperati, 526; speciosus albus, 526; Tomasinianus, 526
Crocuses grown in a pot, 543
Cucumbers in frames, 161
Cupressus Allumii, 729; dwarf, in a rock garden, 730; erecta viridis aurea, 729; macrocarpa, planting hedge of, 230
Cyclamen Coum, 71; Giant White, 528; greenhouse, 353, 527; hardy, 639
Cynoglossum amabile, 232
Cytisus albus, 378; præcox, 553

Daboecia polifolia, 751
Daffodils attacked by narcissus fly, 529; bulbs of, infected with basal rot, 529; dwarf, types of, 551; in an orchard, 519; in window-box, 217; in woodland, 225; testing bulbs for eelworm, 529; varying size of bulbs, 528
Dahlia Belle Mauve, 771; Coltness Gem, 244; Mrs. F. G. Selous, 771; Omeaan, 771; Topaz, 771
Dahlias at Cheal's Nursery, 771; bedding, modern, 812; decorative white, 260; Dobbie's exhibit of, 659; lifting and storing, 668; Mignon in beds, 290; planting out, 292; seedling, 233; single, 481
Daphne Blagayana, 466; Mezereum, 153
Datura suaveolens, 279
Delphinium Belladona, 329; Coquette, 370, 632; Mrs. Foster Cunliffe, 370; Mrs. Townley Parker, 602
Delphiniums, 385; border of, 533, 602; in a border, 196; in mixed border, 196; Wrexham, 677
Dendromecon rigidum, 483
Deutzias in shrub border, 728
Dianthus Allwoodii alpinus, 739; Heddewigii, 638; in the rock garden 650; on rockery bank, 413
Dibber, making a, 146
Dicentra spectabilis, 69
Doronicum, 53, 429
Draba imbricata, 293
Dracæna indivisa, 567
Dripping well in a town garden, 733

Echeverias, planting, 326
Echium tree, 629
Eremuri, 107; bed of, 339
Erica arborea alpina, 655
Erigeron, 7, 155
Erinus alpinus, 414
Erodium pelargoniflorum, 797
Eryngium, 135; giganteum, 700
Erysimum linifolium, 235
Erythronium, 581
Escholtzia, 41, 116, 799; Queen of the Buffs, 212
Euphorbia characias, 328
Evening primroses, 306
Exhibit at Temple Gardens Show, 616

Fabiana imbricata, 450
Ferns, in town garden, 327; in tubs, 776
Flowers, exhibition, 207
Forget-me-nots, by the pathside, 422; cuttings of, 400; in small beds, 364
Forsythia intermedia, 89
Foxgloves in shade, 397
Frames, 794; laying foundations for, 869; placing drainage in, 690; propagating, 709; types of, 172
Freesia, Apotheose, 512; in a greenhouse, 511; potting, 560
Fruit, bottling, 572; planting bush, 72
Fruit trees, grease-banding, 658; protecting, 173, 174
Fuchsias, standard, 275, 298
Funkias, 151, 687
Furniture, garden, 430

Gaillardia, 7
Galega, 135
Garden, attractive front, 755; gates, 613; hose, repairing of, 286, 287; paved front, 261; shelters and summer-houses, 536, 613
Gardens, bog, 21; formal, 250, 352; formal, at Hampton Court, 460; small, 43, 301, 317, 403, 486, 503, 585, 670; small lily pool in, 771; semi-wild, 333, 422; terraced, 423; town, 749
Garrya elliptica, 140, 221
Genista cinerea, 517
Gentiana septemfida, 595; sinoornata, 307
Geranium Mme. Cronsse, 343
Geraniums, in beds, 296; propagating, 604
Gerbera, 417
Geum Mrs. Bradshaw, 69
Gladiolus, a dormant, 182; alatus, 383; Byron L. Smith, 187; Daphne, 186; maculatus, 383; Souvenir, 207; tenellus, 383; White Giant, 187
Gladioli, basket of large-flowered, 812; bed of scarlet, 260; in bed of mixed flowers, 185; in borders, 186; large-flowered, in beds, 197; lifting and drying, 684; planting, 183; potting, 183; primulinus, 180
Gloxinias, propagating, from leaves, 592
Godetia, 188
Gooseberry, cordon-trained, 449; Green Gem, 744; Keepsake, 674
Gooseberries, mildew on, 237
Grape hyacinths in pots, 117
Greenhouse, amateur's, in spring, 240, 301; heating small, with oil stoves, 780; small lean-to, 736; small span-roof, 350; span-roofed, 736; spring flowers in, 752; steel framework, 737
Gypsophila repens, 249

Hampton Court, gardens at, 460
Hand light, 716
Heaths, winter-flowering, 55
Hedges, clipping, 276; planting, 643; planting evergreen, 230; privet, 537
Helenium autumnale, 141
Helianthemum, 151; umbellatum, 483
Helianthus rigidus, 215
Helleborus, planting, 562; orientalis, 580
Hemerocallis, 7
Herbs, drying, 514; garden of, 814
Hesperis matronalis, 22
Hollyhock, Patling Belle, 155
Hollyhocks, 363; in borders, 280
Honeysuckle, on an arch, 714
Hordeum jubatum, 45
Hyacinths, bed of, 511; cynthella or miniature, 510; grown in a shell, 543; grown in water, 562; miniature, in a bowl, 605; mixed, in a bowl, 510; pot-grown, with eight blooms, 27
Hydrangea, paniculata, 428, 48; paniculata grandiflora, 782
Hydrangeas, in pots, 854; in tubs, 317, 777
Hypericum Kalmianum, 655
Hurdles, wattle, 732

Iberis, 325; in the rock garden, 650
Inula, in a border, 396
Ipomœa rubro-cœrulea, 249
Iris, Aphrodite, 462; Delfor, 462; Dominion, 445; histrioides, 51; reticulata, 51; Rosenbachiana, 51; sibirica, 478; Souvenir de Mme. Gaudichau, 445; sibirica, 806; styiosa, 447; tingitana, 447, 532
Irises, by pathside, 445; by the waterside, 477, 569; dividing Siberian, 446; in border with lupins, 444, 574; in formal beds, 574; in town garden, 438; Japanese, by waterside, 584; massed, 502; raising, from seed, 398; Spanish, in border, 203
Itea ilicifolia, 735
Ixia, 596

Jamberry, plantation of, 597
Juniperus hibernica compressa in the rock garden, 780

Kitchingia uniflora, 93
Kniphofias, 39, 171, 638; H. G. Mills, 661

Lachenalia, 482; pendula, 74
Larkspur, annual, 41
Lathyrus, grandiflorus, 313; latifolius, 264
Lavatera, 215; white and pink, 537
Lavender, edging a path, 435
Lawn mowers, oiling, 184; types of, 284
Lawns, in town garden, 153, 247; preparing ground for, 582; treated with "Carterite," 226; trimming edges, 326; weeding, 582
Leek, Sutton's Prizetaker, 209
Leiophyllum buxifolium, 499
Leucophyta Brownii in bed, 412
Libertia formosa, 281
Lilies, Madonna, 332; planting bulbs, 36
Lilies of the valley, 682
Lilium, auratum, 493; Brownii, 492; candidum, 332, 390, 520, 612; dauricum, 476; giganteum, 492; pardalinum, 492; Philippinense formosanum Price's variety, 149; Regale, 477; Regale, raised from seed, 646; testaceum, 103, 476
Lily Pool, 331, 381, 407, 418, 423, 521, 537, 585, 599, 613, 810; constructing a, 380; in town garden, 231, 607; making a, 651; miniature, 691; planting water lilies in, 309
Limnanthes Douglasii, 116
Linum arboreum, in a rockery, 454; perenne, 122
Lithospermum prostratum, 438
Lobelia, B. Ladhams, 215; in the rock garden, 707
Lonicera, fragrantissima, 18; nitida, planting a hedge of, 643; tragophylla, 564
Lunaria biennis, 307
Lupin, Glowworm, 558
Lupins, clumps grown from seed, 202; exhibit of, 371; in border, 291, 558, 799, 808; in a border with irises, 574; massed, 423, 502; seedling, 471
Lupinus arboreus, 362
Lychnis viscaria, 783

Magnolia, on a wall, 19; stellata, 109
Maidenhair fern, 93
Mallow, pink, 154
Maples, Japanese, in a rock garden, 750
Marguerites, bordering a path, 639
Marigolds, 22
Marjoram, 50
Meconopsis integrifolia, 323; paniculata, 340; Prattii, 340; quintuplinervia, 340; violacea, 450
Megasea, 517
Mignonette, 325
Mimulus, 325
Mint, forcing in boxes, 748
Moutbretia Star of the East, 220
Morisia hypogæa, 737
Muscari, edging of, 608; in a pot, 117
Myosotis alpestris, 494
Myrica asplenifolia, 264

Narcissi, potting, 560
Narcissus cyclamineus, 117; Evangeline, 542; Firetail, 543; King Alfred, 542; Poetaz, 654; Premier, 550
Nemesia, 40; in beds, 138
Nemophila insignis, 83, 809
Nepeta, 155; at top of steps, 469; edging a path, 495; edging of, 382
Nigella, 25, 188
Nurseries, Messrs. Allwood's, 739; Messrs. Austin and McAslan's, 722; Messrs. R. H. Bath's, 550; Messrs. Cheal's, 771; Messrs. Dobbie's, 800; Messrs. Lane's, 786; Messrs. W. J. Unwin, 811
Nymphæa marliacea albida, 279; pygmæa, 380
Nymphæas in barrel, 439

Œnothera, 135; biennis, 306; Clutei, 549
Olearia chathamica, 591; Haastii, 9; insignis, 591; macrodonta, 429; semidentata, 591
Omphalodes cappodocica, 387; in border, 203
Onion Ailsa Craig, 253
Ornaments, 452, 670
Ornithogalum, 545; lacteum, 568
Osmanthus Delavayi, 149
Owl, tawny, 487
Oxalis adenophylla, 70; floribunda, 595

Pæonies, 588, 589; in border 133; single, 133; soft pink in beds, 291
Papaver orientale in a border, 558, 806; Perry's White, 298
Paths, 599; concrete slabs for, 94; designs for, 20, 21; flagged, 547; making, 127; 567; paved, 353, 487, 670; paved, edged with alyssum, 352; paved with bricks, 553
Paved front garden, 261
Paving, brick, 553; crazy, 397; 670; laying, 567; round flower beds, 718
Peach Peregrine, 518; scale, 268
Peaches attacked by leaf-curl, 237
Pear Doyenne du Comice, 784; Jargonelle, 316; Louise Bonne of Jersey, 754; Pitmaston Duchess, 113
Pears, shoots attacked by pear scab, 237; young cordon, 113
Peas, protecting early, 56; protecting with lime, 56; supports for, 256
Pentstemon Daydream, 154

PLANT HOLLYHOCKS IN THIS YEAR'S BORDER.

HOLLYHOCKS rank among the best of our stately border plants both in flower and in foliage. The colours of modern strains show a particularly wide range of pure tones that combine well with those of other tall border plants. The tall elegant spikes are especially suited for a background to a wide border and show up excellently well against a bank of evergreens. They are easily grown either from seed or by division, and respond to conditions which are met with in the ordinary garden. They are undoubtedly plants for the amateur and should be included in all herbaceous border schemes this coming year.

THE GARDEN

VOL. XCI.—No. 2874. JANUARY 1, 1927. PRICE TWOPENCE.

NOTES OF THE WEEK.

A Good Gardening Year to all Readers.

WE extend to all our readers, both old and new, our best wishes for a most successful gardening year and abundant crops of flowers, fruit and vegetables. Do not delay, but get right ahead now by making out the seed order and, later on, attending to spring planting of all herbaceous and shrubby subjects.

Bulb Notes for January.

THERE must be thousands of amateur gardeners who never make the mental effort to distinguish between one flower and another of its class and to whom any one of a thousand varieties of daffodils or tulips is just a daffodil or a tulip, white or yellow, pink or red. Always judge flowers for yourself. Mr. P. D. Williams, to whose skilful and patient work among daffodils the world will be ever in debt, has expressed the following formula: The standard of quality and progress in daffodil and tulip culture rests upon four essential supports: (1) The flower must be a good garden flower, *i.e.*, healthy, vigorous and floriferous. (2) It must be a good flower for table decoration, *i.e.*, graceful and pleasing and cheerful to the eye. (3) It must be a good flower for market, which means that in addition to (2) it must pack and carry well, without drooping overmuch; and (4) it must be good for the show bench, when coarseness or refinement of texture and poise, purity of colour, size and vigour are balanced to a featherweight. Bearing these standards in mind, the army of thousands of more or less nondescript varieties of daffodils and tulips will melt away. Now is the time to start afresh, when flowers begin to show. Look over your neighbour's railings! look into the florists' shops.

It is not too late to make a tremendous difference in the quality of your own bulbs. Take ½lb. sulphate of potash, 1lb. super-phosphate of lime, 2lb. dried blood meal or steamed bone flour, add 1lb. kainit if your soil is inclined to be light or dry at flowering time—mix them all together and sprinkle a good dusting round the bulbs, and lightly fork it in. Repeat the dose about the middle of February. If you want to know what effect this mixture will have on your soil, sprinkle a little on part of your lawn and watch for results.

Window Gardening.

ONE of the lesser hardships attendant upon the shortage of houses is the lack of a garden. The lover of flowers, even when living in two rooms, can, however, enjoy to some extent the pleasure of their cultivation by means of window boxes. Suitable flowers can be grown successfully whichever way the window faces, but if it is due north only the hardiest plants should be chosen.

The ordinary window box has many disadvantages. It is too cumbersome and heavy to be moved easily, and when the soil in it needs renewing it can only be done by lifting it out and making a great mess. Old window boxes also harbour all manner of filth.

It is better to have an ordinary window box built, but not filled. The inside may then be painted and kept perfectly clean. Into this a series of smaller boxes or even pots may be fitted, which can be lifted in and out when they require attention and can be renewed often enough to avoid filth. The boxes are more satisfactory, as they fit together and give an ordinary surface, whereas there are bound to be ugly spaces left between pots. If there are sufficient ledges available, it is well to have one box somewhere where it will not be an eyesore to use as a "nursery" for bringing on plants. A good show of flowers can be maintained throughout the spring and summer in this way, as when one group ceases flowering they can be removed in their boxes and others brought from the nursery to take their place.

If the ordinary window boxes are preferred, they should be 9in. or 10ins. deep, perforated at the bottom, and with a 2in. layer of broken pots, stones, etc., for drainage. The soil should always be carefully chosen. As the roots cannot spread, they should be supplied with all necessary nourishment in the space available.

The crocus and snowdrop will be the first flowers in the boxes, and after flowering they should be removed to the nursery box and replaced by hyacinths, daffodils, tulips, etc. After flowering all bulbs should be left in the nursery box until the foliage begins to wither.

If the old-fashioned boxes are used, care must be taken to fill them with plants which thrive under similar conditions. It is a common sight to see geraniums and marguerites grown together, but the full beauty of both is never realised in this way. Marguerites want much water, while geraniums thrive in a dry soil, and if watered too much they produce huge leaves and few flowers. An excellent and cheap filling for a box, especially if it is at an upper window, is nasturtiums. The dwarf variety may be sown at the back and the climbing near the front, and allowed to hang over.

Many of the smaller-growing annuals and perennials, such as primroses, pansies, mignonette, dwarf clarkia and antirrhinum (snapdragon), wallflowers and rock plants may be raised in the nursery box and transferred to the others at the time of flowering. Care should be taken in selecting summer flowers for the window box, as many are inclined to run up quickly to the light and present nothing but rows of scraggy stalks to the occupants of the room.

HAVE YOU

¶ *Sent off your seed order?*

¶ *Protected your newly planted roses?*

¶ *Removed all fallen and decaying leaves from your rockery?*

¶ *Cleaned and washed down your greenhouses and cleared up your tool sheds?*

¶ *Protected with mats or sacking your tender shrubs on walls?*

¶ *Covered with boxes and litter or fallen leaves a portion of your rhubarb plantation in order to secure an early supply?*

¶ *Lifted a few roots of mint and placed them in boxes in the greenhouse? In a short time fresh young shoots will be produced.*

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 5, which appeared in our issue of December 18th, have been awarded to

Mr. John Gemmill,
Oxenward,
Kilwinning, Ayrshire.

and

Mrs. Manser,
4, Heath Grove,
Barming Heath, Maidstone.

To each of whom a cheque for that amount has been sent.

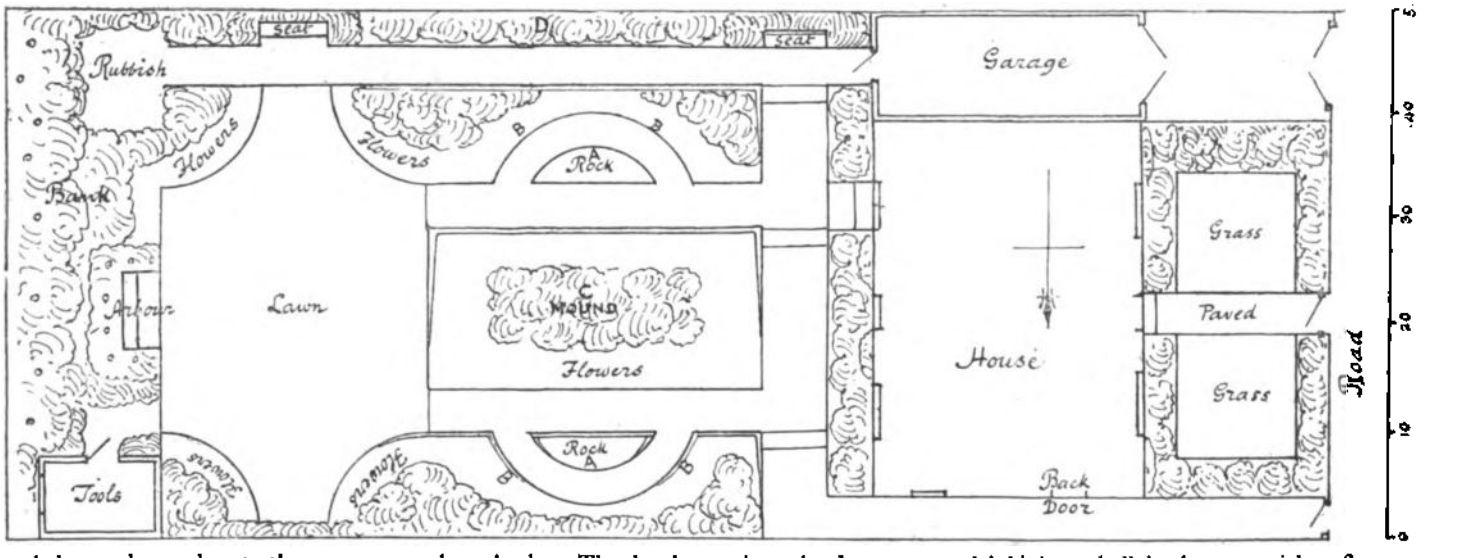
THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

THIS is a small site with a frontage of 50ft. to the road and a depth of 130ft. The ground slopes across the length, being highest on the north side. The house therefore stands higher than the garage and the wall between is carried forward to the road at such a level as is necessary for retaining the soil of the small front garden. The front of the house is only about 17ft. from the road. The two little square grass plots with the paved path between are levelled across, and any further discrepancy in the levels is got over by easing the ground beyond on each side, this device being hidden by the shrubs planted to right and left.

The path on the eastern or garden side may possibly go down on one even slope, but it is much better to have three sets of two or three shallow steps as shown. There is always in building a house a certain amount of rough earth that comes out of the foundations. This can be well used to form the central mound C. To keep it fairly evenly balanced, it will have to have two or three courses of dry walling on the south side, and the southern edges to the spaces on each side will require the same. This is shown on the plan by a double line. This slight walling dies away to nothing on the returns, as it meets the higher levels. The middle of the mound C may well be planted with small shrubs, best of all with the common berberis (B. Aquifolium), which gives a quantity of bright yellow bloom in earliest summer and beautiful foliage all the year round. Then will come flowering plants, nothing very tall, but such as the beautiful purple catmint (nepeta) and some of the short-growing annuals—dwarf nasturtiums, sweet alyssum and mignonette. The little half moons, A, A, should be treated as rock beds, mounded up, and with enough stone or any rock garden material as will keep the earth in place. Anyone who is handy and inventive can make good rock stuff with bits of coke or even cinders, with a little clean sand and Portland cement and a dash of umber in powder to counteract the cold grey of the cement. Then the edges of the outer half-circles, B, should also have rock plants—aubrietia, alyssum, stonecrops, saxifrages, arabis, iberis and so on, so keeping a rock garden effect. Farther back will be flowers and then a general backing of flowering shrubs. The border against the house on this side will also need some dry walling to keep it on one level. This will suit the best things for such a place—lavender, rosemary, santolina, etc., which like nothing better than a rather high and dry position.

It would be too much of a job to level the lawn, but it is best in such a case to let it run on one easy slope from north to south; the two paths on either side of C will then run out to it at their own levels, or with such slight easing as may be required. The arbour would be notched into the base of the bank which forms the east end of the garden and which has already some well grown trees at the back. The shrubs backing the flower borders at this end should be mostly evergreen, some Portugal laurels and then laurustinus. The whole surrounding of the rubbish place had better be of the broad-leaved form of the common laurel, which would come far enough up the border D to enclose the lower seat. The seat on the same side near the house should have yews at the back and sides. The space in D between the two seats will be for flowering shrubs or bush fruit trees. Flowering plants that are too tall or bulky for the margins of C and the curved portions of B, such as delphiniums, hollyhocks, perennial sunflowers, etc., will find their places in the circular borders at the angles of the lawn.



PINKS FOR THE SMALL GARDEN

THE formation of a collection of the various species of a particular genus of plants is certainly one of the most fascinating of garden hobbies. For this purpose no group of plants is more suitable than the pink family. They are singularly easy to raise from seed, which can be obtained without any very great difficulty in quite small quantities for a very modest outlay. Most gardens will be sure to contain a few varieties of the "ordinary common or garden" pink, and there is certain to be a clump or two of Mrs. Sinkins not very far off. Then, there is the nice old-fashioned pink form of Dianthus plumarius beloved of cottagers; and need I mention the perpetual-flowering pinks which have made the name of Allwood famous? The Indian pinks, too, which are capable of making such a brave display in the mass.

But it is of the little rockery pinks that I would speak, splendid subjects for the old wall and the rock garden. All the pinks are, indeed, most suitable for these situations. The grey foliage possessed by many of them is such an attraction in winter, when there is not much to interest one between the stones.

Our own native flora supplies us with three pinks, though, apparently, one of them (D. Armeria) does not appear to be considered worthy of a place in our gardens.

The Cheddar pink (D. cæsius), which is to be found among the crags of the Cheddar gorge, forms delightful little cushions of grey foliage, from which rise rosy fragrant flowers in the spring. It loves a well drained limy soil, and is happiest on an old wall.

The maiden pink (D. deltoides) is another native with pretty, small pink flowers produced in great numbers on tall straggly stems throughout the summer months. For a good effect plant this close to one of the smaller blue harebells. The wiry stems of the campanula help to support those of the pink, and the flowers blend beautifully together.

The alpine pink (D. alpinus) is characterised by its dark green shining leaves, from which the solitary deep rose flowers project but a few inches. They are flecked with crimson, and are at times produced with such profusion as entirely to hide the foliage. There is a very attractive white form of this pink which is well worth growing.

The glacier pink (D. neglectus), with narrow grass-like leaves and cherry red flowers, is a perfectly charming little plant and, moreover, a good perennial not given suddenly to dying off for no apparent reason as, it must be admitted, so many of these small alpine pinks are too prone to do. It is a very variable plant, but all its forms are pleasing. A minute species with rosy purple flowers is D. acaulis, making the neatest of tufts. The list is a long one. Those I have singled out are certainly some of the best and, perhaps, the easiest to acquire, but there are many more for the enthusiastic collector. — EDWARD CAHEN.

THE ROCK GARDEN

Saxifrages for the Small Rockery.

THE saxifrages are certainly the glory of the rock garden; they offer a great variety of colour and size, as well as beauty of form. For the very small rock garden, careful selection is necessary, as many are too large, or of too vigorous growth, for comfort. It may be well to mention first of all some which should be excluded where space is really limited—there are so many other lovely saxifrages that their absence matters very little. First, there is the whole megasea or bergenia group from the Himalayas and Siberia—cordifolia, ciliata, crassifolia, ligulata, Stracheyi, and so on—big cabbagy things, best in the front of the border. The American swamp saxifrages are too coarse, and not attractive—Forbesii, pennsylvanica, etc. Most of the forms of S. umbrosa and S. Geum are also too vigorous; and the same must be said of most of the mossies, especially decipiens, hypnoides, moschata and trifurcata and their varieties—though a few exceptions will be mentioned later on. Having thus cleared away a lot of unsuitable plants, we can proceeed to the selection of small, choice and not difficult forms. These belong mainly to two groups, the silvers (section Euaizoonia of Engler) and the kabschias. Of the former, the well known S. Aizoon is typical—a wide-spread alpine plant, and very variable: the Kew Hand List includes twenty varieties. All are easy, and we can vary the usual white of the blossoms by introducing the red-flowered var. rosea, the pale yellow var. flavescens, or the densely red-dotted var. balcana. S. cochlearis and its vars., major and minor, are very neat and pleasing, forming close silvery patches with graceful sprays of white flower. The same can be said of lingulata and its varieties, the one named lantoscana being a specially well flowered form. Then we cannot do without S. longifolia, with its splendid great single rosette of narrow leaves; but it has the disadvantage of dying after flowering, which makes some people prefer its perennial hybrids. S. Cotyledon is one of the finest of rock plants, and for its varieties, pyramidalis and caterhamensis, no praise can be too high: their strong silvery rosettes and great waterfalls of flower place them in the very forefront of rock plants.

The kabschias are all very small-leaved plants, forming dense, often prickly cushions, from a few inches to several feet across. They include the most treasured of the saxifrages, and while many are rather difficult, there are, fortunately, others which give no trouble, and grow and flower with delightful freedom. The easiest of all are the primrose yellow apiculata and its white variety, the similarly coloured Elizabethæ, and the deep yellow sancta. All of these will form a cushion 1ft. to 2ft. across, but they get ragged eventually, and look best as smallish clumps in niches of the rockwork. S. marginata is a good reliable plant, and the several forms sold as Rocheliana likewise: both are white-flowered. S. cæsia is one of the tinies, very dainty and also white. If we wish to get away from whites and yellows, we may venture on the lovely little pinkish Irvingii, or we may try one of the larger fluffy-flowered "red kabschias," such as Stribnryi or media. Last but best of all, the January-flowering S. Burseriana should have a choice place high up on the rockwork: the big pure white flowers of it and its varieties, and its grey spiny foliage, place it in the forefront of the group. We cannot altogether omit the mossies or the Robertsonias, previously referred to. The red mossies, of which there is now such a wealth, are essential in the smallest garden, and a selection will be found in the catalogue of every nurseryman who touches alpines: but plant them away from the smaller treasures. Of the Robertsonias, one species, S. cuneifolia, is quite neat and well behaved, and one variety of the London Pride, S. umbrosa var. primuloides is small and especially pleasing, with pink flowers set on red stems. Of saxifrages of other kinds, the flat trailing S. oppositifolia and its smaller ally retusa bring in a rosy purple colour which is very welcome among so much white; and S. aizoides var. atrorubens has flowers of a unique orange red that is most effective: a comparatively damp place is the best for this last. Finally, if we have a moist niche protected from autumn frosts, S. Fortunei with its delicate butterfly-like blossoms will furnish us with a delightful surprise in October. The Saxifrages which may, therefore, be recommended for the beginner in rock gardening, and with a limited space at his disposal, are as follows:

Saxifraga Aizoon and varieties rosea and flavescens.
S. cochlearis and varieties minor and major.
S. longifolia, S. lingulata.
S. Cotyledon.
S. apiculata, S. Elizabethæ
S. marginata, S. Burseriana.
S. cuneifolia, S. oppositifolia, S. aizoides and varieties. S. Fortunei.

R. LLOYD PRAEGER.

THE ARCHING SPRAYS AND WHITE FLOWERS OF SAXIFRAGA LINGULATA ADD MUCH BEAUTY TO EVEN THE SMALLEST ROCK GARDEN.

DRIFTS OF MOSSY SAXIFRAGES MAKE FOR GORGEOUS EFFECTS IN EARLY SPRING.

THE BUSY MAN'S PAGE

Garden Resolutions for the New Year.

GARDENERS should not only make good resolutions for the New Year, but should take care to keep them. Here are twelve rules which it pays to bear in mind:

Make a practice of digging deeply, for the more the soil is broken up the better will be the crops.

Carry on a continual war against the weeds and never allow any to flower and set seed.

Use the hoe frequently to keep the surface soil well broken and so let plenty of air into the ground.

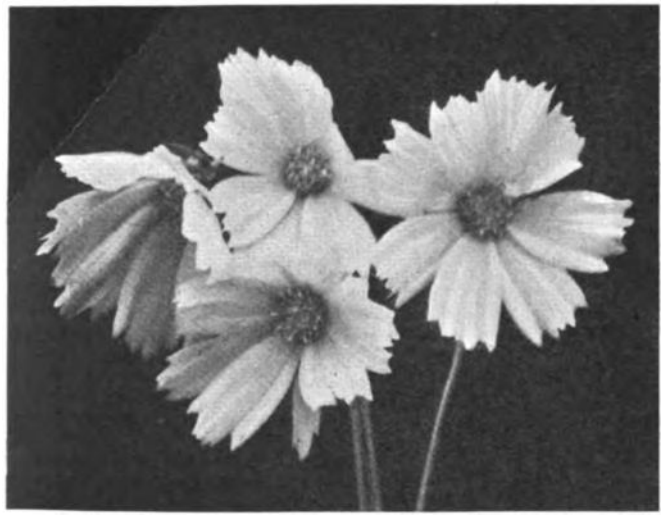
Give manures and fertilisers which are best suited to the particular crop.

Buy only the best seeds and place your order in good time.

Choose plants and varieties which are most likely to thrive in the soil and conditions of your particular district.

Sow rather thinly and thin out all seedlings in good time.

Keep a sharp look out for all pests and never lose an opportunity to destroy these.



THE STARRY FLOWERS OF COREOPSIS GRANDIFLORA. A DECORATIVE, EASILY GROWN PLANT FOR THE SMALL GARDEN.

Make good use of all your land, but avoid the mistake of anything like overcrowding.

Plan for a succession of crops of the quick-growing vegetables.

Gather all crops when they are ready and so allow the plants to continue producing.

Whenever possible employ rotations of crops and avoid growing the same kinds of plants on the same land for two successive seasons.

A Sure Rat Trap.

A RAT trap which hardly ever fails to make captures is easily fixed up in the following manner: Get a wooden tub or anything similar and a sheet of stiff brown paper which is big enough to tie right over the top. It is important for the success of the trap that the paper should be stiff and springy, the soft paper that is easily torn not being suitable. Place the tub in the position where the rats are most likely to be, and then pour in water to about two-thirds of its capacity. Now stretch the paper right over the top, tying down firmly at the sides with string. Take a sharp knife and in the middle of the paper cut two lines crossing each other at right angles. The lines might be about 6ins. long. Round about where the cut has been made in the paper sprinkle a little grain, bread crumbs or anything that would act as a bait for the rats. Rest a short plank from the edge of the floor to the rim of the tub to provide a means by which the rats can pass upwards. The workings of the trap are simple enough. A rat smelling the food scrambles up to the top of the tub and is soon over the cut part of the paper. This naturally gives under the weight of the rat and the creature is let down into the water. The stiff paper springs back to its original position, so that the trap is self-setting and is at once ready for another capture.

Limewashing Fruit Trees.

THE limewashing of fruit trees is a good way of ridding them of moss, lichen, insect and fungoid pests. By far the most convenient and effective wash is lime-sulphur of 1.3 specific gravity, which can be bought ready made in drums from any of the insecticide firms which advertise in the pages of THE GARDEN. All one has to do is to dilute the substance with water just before use according to the directions given by the makers. Choose a fine dry day to apply the wash, which must always be used before the least movement in the buds of the tree has started. Apply the wash with a brush or a spray, working downwards from the branches to the trunk. Probably a brush is really the best thing to use, especially in the case of older trees, for it is then possible to work the wash into all cracks.

Some Perennial Coreopsis.

ONE of the finest of subjects in the herbaceous border is the coreopsis in its perennial varieties. They bloom for a long period commencing as early as May and providing the house with cut blooms as late as the end of August.

The shortest-flowered variety is Coreopsis verticillata, blooming from July to August. It is a very showy border plant, however, of a fine yellow colour, and grows to a height of 2ft. The variety C. grandiflora is one of the finest sorts, producing many flowers of a very bright yellow and reaching a height of 2ft. to 3ft. This variety, which is illustrated, may be grown from seeds sown in March. These will flower as early as July.

For a large semi-double sort, the C. grandiflora Perry's variety is truly charming. It bears semi-double flowers of a deep golden yellow, and of a size larger than the others.

For a dual-coloured sort, one may choose the C. oculata, which is a yellow flower with a crimson centre.

The plants may be purchased now and planted any day when the soil is nicely workable and not in the least frost-bound.

Some Uses for Cotoneaster Simonsii.

AMONG the shrubs often offered at a cheap rate by the trade, few of these which can claim to be ornamental are at the same time so useful as Cotoneaster Simonsii. In the first place, it makes a very serviceable and ornamental hedge, for it is rigid, stands clipping well, and this does not prevent it berrying, for the fruit appears on the old wood, even right down the stems. The berries, moreover, which are nearly as large as a kidney bean, are a bright scarlet, and they remain on the branches long after the leaves, which turn a blood crimson and orange, have fallen. The fact that C. Simonsii is a very fast grower is in its favour as a hedging plant, and it is robust enough to hold its own with quick, beech or myrobalan, to all of which it will lend the beauty of its autumn-winter colour. This cotoneaster is a first-rate wall shrub, growing rapidly and closely in almost any aspect. It also affords an admirable support for clematises, Tropæolum speciosum and other climbers.

Removing Putty.

PUTTY tends to become extremely hard with age, and its removal from a pane of broken glass is usually a difficult matter. One of the quickest ways of softening putty is by means of a hot iron. A bar of iron like a poker is made hot but not red hot, and this is passed slowly over the putty, the heat so softens the putty that it can be easily worked away with the fingers. Any of the putty which resists the first application of heat may be easily softened by a second use of the hot iron. A lump of unused putty that has been placed on one side will become very hard. This may be rendered soft and workable by beating with a hammer on a hard surface.

The Garden Tools.

IT is impossible to garden successfully without a fairly complete outfit of tools. At this time of the year it pays to overhaul one's implements to see if these are in good condition and to make replacements where needful. A proper outfit of garden tools should include all, or nearly all, the following:

A spade of fair size and with a long blade which is not too heavy.
A smaller spade for light work.
A five-tined fork.
A fork with four broad tines.
A hand fork for dealing with small plants.
A trowel.
A 10in. rake.
An 8 n. draw hoe.
A 6 n. push hoe.
A pair of shears.
Pruning secateurs.
A syringe with jet, rose and spraying nozzles.
A garden line on reel.
A 1½ gallon watering-can, also one of double this capacity with roses.
A wheelbarrow.
A lawn mower.
A roller.
One or two besom brooms.

How Far Apart?

WHEN fruit trees are being planted the spacing should allow for the full growth of the trees and bushes. The following table indicates the space which should be given in the case of the commonly grown fruit trees and bushes.

	Feet.
Standard trees (apples, pears, plums, cherries)	30
Pyramid and bush apples and pears	8–12
Pyramid and bush cherries and plums	7
Gooseberry and currant bushes	5
Espalier or wall-trained trees	15

Of course, pending their full development, standard trees may be grown in association with gooseberries and currants of small size. As the trees extend and shut out the light the bushes will have to be thinned starting with those nearest to the trunks.

THE FLOWER GARDEN

The Flowering Currant.

IN these days we have so many choice flowering shrubs to choose from that one is tempted to underestimate the value of some of the kinds introduced many years ago. Among the latter will be found R. sanguineum, or flowering currant, a charming shrub, even superior to many modern introductions. It never fails to produce its numerous drooping racemes of deep rosy red blossoms during the month of April. This, the best of the ribes, is deciduous, and will grow into a fine bush from 6ft. to 8ft. in height.

R. sanguineum is a variable plant, and a number of named varieties can be found in catalogues. In addition to the type there is a white form known as album; also atrorubens, with deep red flowers, but less free in its habit of growth; and splendens, no doubt the finest variety known. This form produces longer racemes of larger flowers, while the brilliant colour is a great improvement on the type. It is a most desirable and ornamental ribes, and if only one form is grown this should certainly be selected. Although an old-fashioned shrub, it deserves the renewed attention of every one interested in spring-flowering plants, for which many gardens are noteworthy. Furthermore, it is not fastidious regarding either position or soil. In the front line of the shrubbery, their brilliance will furnish a welcome bit of colour in an otherwise sombre place. There are often open spaces in the garden where R. sanguineum would be quite at home, and very attractive in the spring; while hedges could be formed, to divide one part of the garden from another, but not of sufficient strength to keep out cattle.

In fact, the various forms of flowering currant can be planted almost anywhere, and are sure to give a good account of themselves annually.

Any pruning or cutting back should be done immediately after flowering, but this is only needed if the plants are exceeding their allotted space.

THE GRACEFUL CLUSTERS OF ROSY RED BLOSSOMS OF THE FLOWERING CURRANT.

Propagation is by cuttings made from well ripened wood during the autumn months, and set out in lines in the open ground.—T. W. B.

Weeping Roses.

AT all times beautiful, the rambler rose is exceedingly pretty when grown from the top of tall standards to form what are known as "weeping roses." Such roses are expensive, and that fact alone renders care and attention imperative both at planting-time and afterwards. In the first instance, it must be understood that weeping roses require plenty of space to look their best. Planted in an open lawn or open flat border with little round them to detract from their appearance they will give delightful artistic effects, but even a single specimen in a good site lends enchantment to the general aspect. Weeping standards always require firm planting and equally firm staking; the placing of the stake must be done with care, also, to avoid injury to the roots. After that is done see that long streamers are secured so that gales may not blow them to tatters or tear them away from the crown. I do not like those wire umbrella-frame trainers which some growers use; nothing can excel the beauty of a rose where the long, slender branches droop in a natural cascade of artistic beauty. During winter, especially the first winter, a little protection may be given to the point where the rose has been budded. A handful of ferns or straw twisted round this vital spot does quite well, although more careful growers tie up the branches, thatch them with straw or ferns and leave them thus till all danger from severe weather is past. The question of variety or varieties is a difficult one. Personally, I pin my faith to the old "tried and true" kinds, from which selection some of the very finest specimens may be grown. What pretty and delightful things are Excelsa, the old pink Dorothy Perkins, White Dorothy, Blush Rambler, Albéric Barbier, American Pillar and many others well known in gardens in some shape or form! Less common, but glorious things when they are well grown, are Joseph Billard (early), Delight (late), Auguste Barbier (early), Aviateur Bleriot (saffron yellow), Léontine Gervais, Sweetheart, Troubadour, François Foucard (lemon), Gardenia, Tausendschön, Longworth and so on.—CLYDESDALE.

Lobelia cardinalis and its Allies.

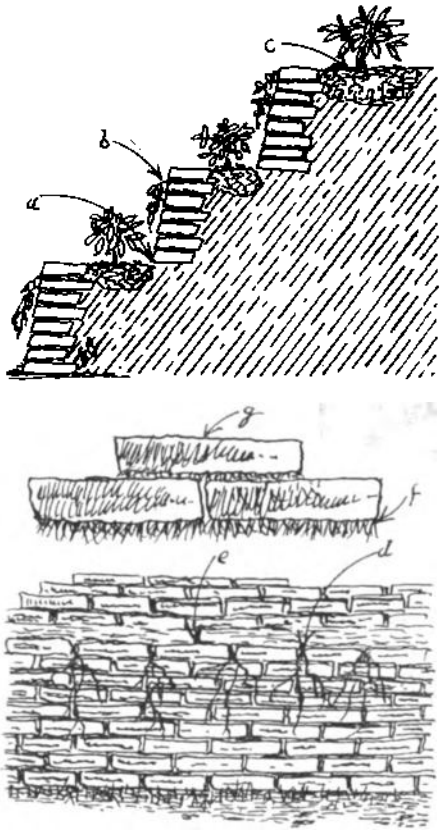
THE cardinal flower—Lobelia cardinalis—a perennial plant of North American origin, is valued by reason of its distinctly coloured flowers, which are considerably enhanced by coppery green foliage in autumn. It is a plant that strikes an amateur as something out of the ordinary — something that compels admiration — and desire for possession is usually followed by acquiring young ones in spring and planting them in the garden. But unless he understands that the term "perennial" does not always carry with it hardiness, and if he leaves the roots out of doors to the tender mercies of the winter, the probability is that all or, at any rate, most of them will die. No species of perennial lobelia is more popular once its requirements are understood and carried out. It loves shade and moisture, a rich soil in which leaf-mould and decayed manure form part, and needs to be lifted and placed in a cold frame for the winter to ensure its existence. Even then it is not wise to rely solely on old plants, but to sow seed occasionally in pans of light soil in a frame in spring. The seed, being very fine, should be mixed with a little of the compost to ensure its better distribution in the pan. There is a variety bearing scarlet flowers and red leaves and stems, known by the appropriate name of Firefly. L. fulgens is a species native of Mexico, with mulberry red flowers and deep metallic stems and foliage. It is at its best in autumn. Queen Victoria is a variety having handsome scarlet flowers and purplish foliage. L. syphilitica, also of North American origin, has many varieties, blooming from early summer to autumn. It is the hardiest of the species, giving us blue and rose and white blossoms. A number of hybrids, too, such as Feltham Beauty, Rosalind, and Sam Barlow, are worthy of the attention of all interested in the family. One very striking species, L. Tupa, from Chile, with broad green leaves covered with white down, has reddish purple flowers, which always command admiration. This, to my knowledge, stands the winter in north Wales without protection, but the situation is a sheltered one.—W. L. L.

Planting Shrubs on Terraced Banks.

WHERE banks are very wide and gently sloping, shrubs, trees and other plants may be successfully grown on them without forming terraces. But it is almost useless to attempt to establish shrubs on steep banks

Digitized by Google

unless such banks have been converted into a series of terraces. On the steep bank shrubs may grow freely and do nicely for several years, then we experience a very hot, dry summer and the specimens suffer so much



that some may die, while others do not properly recover for a long time afterwards and their general appearance is not attractive. I have had much to do with the terracing and planting of steep banks and have found that the plants never suffered during dry summers like others in gently sloping borders. Of course, the work should be well done in the first place. The front portion of each tiny terrace, in the case of a very steep bank, should be shored up with turves laid brick-fashion and with the face slanting backwards a little. A shoring wall of peat is better than one of turves from a meadow because, in dry weather the peat becomes very dry and prevents water running away from the roots of the plants behind them. The turves should be uneven in size so that some will be laid farther back than others, as shown in the sectional sketch, and become wedged, as it were, and not likely to bulge outwards. At *a* the turves are shown, at *b* trailing plants which will, in time, serve the purpose of binding together the turves forming the retaining walls. At *c* the main plant, the shrub, is shown and for the benefit of all such plants good loam should be placed there. At *d* and *e* the front of the wall is shown and terrace. At *f* and *g* the right way to arrange the turves is shown, grass side downwards and as bricks in a wall are laid.—G. G.

Pyrus Vilmorini.

THE planting season is now in full swing, and those who contemplate including a few berried subjects would do well to include the plant quoted above. Seeds were sent from western China by the missionary, Père Delavay, in 1889, to M. Maurice de Vilmorin, who raised plants in his garden at Verrières. For the greater part of the year this small tree or shrub is most attractive. Its chief feature will be found in the pale rosy red fruits which are produced in abundance, and are most conspicuous during the autumn months if the birds leave them alone. The elegant pinnate foliage is most pleasing, and during June the trees are practically covered with corymbs of white flowers. P. Vilmorini belongs to the Aucuparia section of pyrus, which includes the mountain ash or rowan, and it is a plant worthy of wider cultivation. It is hardy, and will thrive in ordinary garden soil. If it is decided to place a group or a few plants in pasture land or similar position, the ground should be trenched, and if the soil is poor a dressing of manure will be an advantage. This plant is increased by seeds, grafting and budding. It is always interesting to raise a batch of seedlings, as some may be an improvement on the type.—T. B.

Lady Larpent's Leadwort.

THIS very beautiful plant came to us from China some seventy-five years ago. It used to be known as Plumbago Larpentæ, Sir William Hooker contending that its name should be Valoradia plumbaginoides. However, no sooner had we become accustomed to the former name, than someone who did not flinch from adding to the terrors of life came along and rechristened it Ceratostigma plumbaginoides. In spite of this, Lady Larpent's leadwort continues to be the delightful little shrub that it always was. Making a little thicket of 1ft. leafy shoots, these terminate in August in a close-set cluster of blossoms in a deep, pure azure. Thence, for a month or more, a succession of these lovely flowers will be maintained, when the leaves assume rich shades of orange and crimson before they are shed.

This species loves the hottest, driest and poorest of gritty soils in full sun, and if it has some half-sunken stones under which the roots may run to put up fresh shoots on the other side, it will be so much the happier. It never spreads far or fast with me, a clump some fifteen years old now only covering some 2–3 sq. ft. No attention is ever given or needed, but the growths are cut back to the ground level every spring. By leaving these untouched the flowering season would certainly begin rather earlier, but the clipping encourages a denser growth and larger leaves and flowers.—A. T. J.

The Cornelian Cherry.

SEVERAL years ago Cornus Mas, or the Cornelian cherry, was a popular plant, and was held in high esteem as an early-flowering shrub or small tree. The cornel tree is a native of Europe, and has been in cultivation in England for a large number of years. If planted in a situation that suits it, a height of 15ft. or 20ft. will be attained, and such a specimen in full flower is a welcome sight in February or March, according to the mildness of the season. The illustration shows cut branches of this pretty cornel, and not only does it illustrate the habit of flowering, but also shows how desirable it is for vases at the dull period of the year, when flowers are scarce. The individual flowers are small and yellow, and are most conspicuous against a dark background, especially when the sun is shining during the afternoon.—B.

Daffodil Disease.

"FUSARIUM," "Basal Rot," "Bulb Rot," or "Bolziek." Although this is a well known infectious complaint the general apathy shown by people who should know better is nothing short of astounding. The disease has been described both in this country and in Holland, but it has not been made the subject of any extensive research. The affected bulb goes brown and "roxy," like an over-ripe pear. The inner scales under a strong handglass appear as brown granulated jelly and frequently teem with mites (Rhizoglyphus echinopus), not unlike cheese mites. Under the glass they are easily discernible, feeding on the diseased substance of the bulb scales. The burning of all affected bulbs is the only known method of preventing the complaint from affecting sound bulbs. Bulbs apparently unaffected, but liable to be so by reason of their contact with affected ones, should have their outside scales removed and be dipped in a solution of one fluid ounce formaldehyde to three pints of water. The bulb, while damp, should be well dusted with flowers of sulphur and planted as soon as possible. The throwing of diseased bulbs into adjoining dykes—a practice common in Holland—is greatly to be deplored. Sterilising by heat is useless as a cure for Fusarium.

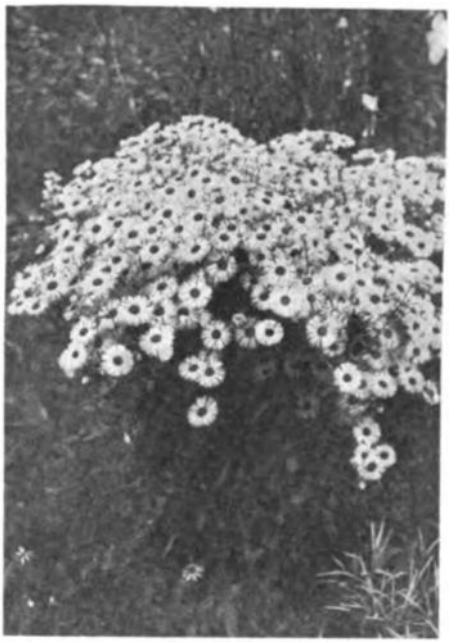
This complaint should not be confused with "eelworm," which is capable of definite control by hot-water treatment. Bulbs affected by "eelworm" parasites only go brown as succeeding healthy scales become affected and the base retains its vitality and is capable of regeneration and healthy growth after treatment, if any life at all remains, whereas in basal rot the base is the first part to become affected.—HERBERT G. LONGFORD.

THE FLOWERING SPRAYS OF THE CORNELIAN CHERRY MAKE ADMIRABLE INTERIOR DECORATION IN EARLY SPRING.

THE ELEGANT AND GRACEFUL DAY LILY.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow in the garden.



THE SUN-LOVING FLEABANE.

Hemerocallis (Day Lily). GRACEFUL, stately plants, yielding quantities of blossoms from June to September, and succeeding in any garden, provided they are given a generous, well manured soil. They vary in height from 18ins. to 4ft., and are most attractive in a border. Flowers are fragrant, and follow each other quickly. When planted in a border, they need to have plenty of room, not less than 2ft. to 3ft. apart, and have mulchings of manure in early summer. Hemerocallises should be taken up, divided and replanted every three years or so, an operation best done in late autumn. Propagation can also be from seed sown in April in a frame in light sandy soil.

Nepeta Mussini (Catmint). IS a perennial herb, aromatic and absolutely hardy. It is one of the best plants for edging. If used in the rock garden, care must be taken to keep it in check. The smoke blue flowers are borne in great profusion from May to September. Plant in March and April. Propagate from cuttings, 2ins. to 4ins. long, taken at a joint in July, which will be found to root easily in sandy soil in a frame, or in the open ground. Remember that the more sun it gets, the more profusely it will flower. It prefers light, sandy soil and if planted in clay, the latter should be well worked and broken with gravel or road scrapings and wood ashes.

Campanula pyramidalis (Steeple Bellflower). AMONG the numerous species of campanula, pyramidalis, the steeple bellflower, is one of the most vigorous. It is tall, often rising to a height of 5ft., and makes a splendid plant for the back of a border or for growing in pots in a cool house. Flowers will give practically three months beauty from July, provided the spent blooms are picked off. A moderately rich soil is best for campanulas, and staking is essential. They are increased by dividing the roots immediately after they have bloomed, also from seeds sown in spring either in a cold frame or house, in pans of light soil. Replanting can be done during the month of March.

Gaillardia (Blanket-Flower). VERY showy hardy perennials that are highly prized for the brilliancy and liberal output of their blossoms, which are most useful for cutting; moreover they bring a deal of colour in the garden, and flower practically from June to early October, and longer in a mild autumn. Gaillardias should be given the advantage of the sunniest positions and a soil that is light and rich. It is of assistance to the plants if some ashes are spread around the roots in late autumn. Their height is about 18ins., and that space should be given between the plants. There are three methods of propagation which amateurs can easily practise, *viz.*, by dividing old plants in April; from seed sown in boxes of light soil in a cold frame or house in April or May, and from cuttings taken in late summer and set in pots of sandy soil and kept in a cold frame during winter.

BRIGHT AND COLOURFUL GAILLARDIA BLOSSOMS.

Erigeron (Fleabane). THESE plants are lovers of sun, and should be given a position where it will reach them. They are easy to grow and will give good results in any moderately rich soil so long as the position is not too dry. Their blooming extends over several months, and they are very effective if planted in groups about a border. None is much over 2ft. in height. They can be increased by dividing the roots in autumn, or in March, or by seed sown out of doors in light soil in April.

Annual Larkspurs. THESE very showy hardy annuals have come to be recognised in quite a number of gardens as essential to a summer display, and every year they are gaining in popularity. One may have them in dwarf plants, or about a foot in height, to those of three feet, and the best of it is there is scarcely a garden where they will not grow. There is no need to nurture them beyond being careful to sow seeds on a warm, sheltered border about the end of April, and if this is done thinly, the young plants can be transferred straight to their flowering quarters when two or three inches tall. Larkspurs like a somewhat light, yet rich soil, and if a little spent hops, or old manure is worked in the border, one may have a gay display. The taller sorts should have the benefit of support by a few sticks. They bloom most profusely during July and August, and in present day sorts there is a splendid variety of colours.

Lunaria (Honesty). THE silvery pods of honesty are very acceptable to all who make a point of growing flowers for winter decoration, and though the purple and white flowers of this biennial are not without value in a border in summer, it is really the shining inner seed pods which, when dried, are the more sought after. Lunaria is a simple hardy biennial, needing to be sown out of doors in a sunny position in ordinary soil in May or June, pricked out and planted in its final quarters in autumn. It commences to bloom in the following May or June, and the stems should not be gathered until quite dry, which will not be before August. Plants grow about 2ft. in height and should always be planted in a warm position.

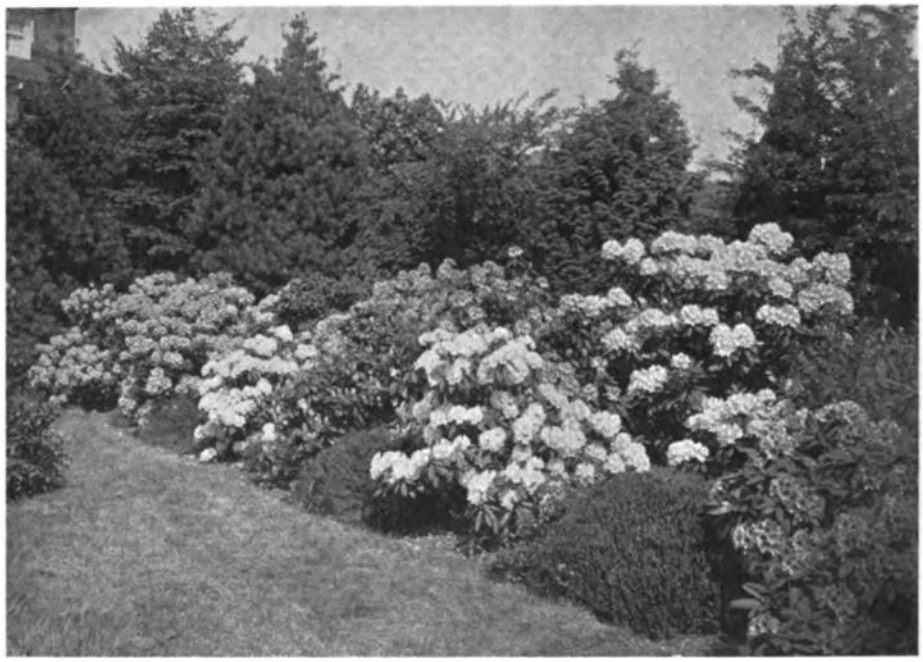
CHOOSING SHRUBS FOR SPECIAL SOILS

One of the most difficult problems which confronts the amateur gardener is the selection of plants for special soils. The accompanying lists of shrubby plants should prove most helpful to those who are faced with this difficulty and will greatly assist them to make a choice of subjects for spring planting.

MANY gardeners do not give sufficient attention to the point that, to a considerable extent, the nature of the soil should control the actual plants which are grown. Soils vary a great deal in different districts, and even in the same localities differences in the character of the land are to be observed. Of course, there are certain plants which will thrive in almost any situation, but, generally speaking, the majority are not so accommodating. To get the best results it pays to give plants those rooting mediums which experience has shown to be the most suitable. Of course, where the ordinary flowering plants of bed or border are concerned, it is usually a simple matter to bring the soil into almost any desired condition. In the case of shrubs and trees such adjustments in the soil are not possible to any great extent, and here it is really important to choose subjects which one knows will flourish in the natural soil. The following lists will help in making a decision as to what shrubs and trees to grow in the particular types of soil. In some cases it will be noted that the plants are repeated in more than one of the lists and such subjects can be relied on to give good results in varying conditions. On the other hand it cannot be too strongly emphasised that there are large numbers of plants which would give excellent results in one kind of soil but fail badly in another.



RHODODENDRONS SHOULD FORM A PART OF EVERY SHRUB BORDER WHERE PEATY SOIL CONDITIONS OBTAIN.

Clay Soils.

Land of this nature will contain upwards of 50 per cent. of clay, and, although it may be improved by digging, drainage and the addition of light sandy material, the soil remains relatively stiff and cold. Suitable subjects for a clay soil may be selected from the undermentioned :

Acer dasycarpum and A. platanoides, two really striking maples.
Amygdalus communis (almond).
Aucuba japonica.
Berberis Aquifolium and B. Darwinii.
Betula alba (silver birch).
Buddleia globosa.
Cerasus Laurocerasus (laurel), C. lusitanica (Portugal laurel), C. Avium and C. Padus (flowering cherries).
Clematis Flammula, CC. Jackmanii and vitalba.
Colutea arborescens (the bladder senna).
Cornus Mas (the Cornelian cherry).
Corylus Avellana.
Cotoneaster buxifolia and C. microphylla.
Cratægus (hawthorns) in variety.
Cytisus (broom) albus, CC. biflorus, purpureus and scoparius.
Deutzia crenata and D. gracilis.
Diervilla grandiflora.
Euonymus in variety.
Garrya elliptica.
Genista hispanica.
Hamamelis arborea, HH. japonica and virginica
Hypericum calycinum.
Hollies.
Jasmines.
Kerria japonica.
Laburnum.
Magnolias in variety.
Philadelphus coronarius.
Pyrus japonica.
Rhus Cotinus and R. glabra.
Ribes (flowering currant).
Robinia Pseudacacia.
Rosa repens.
Sambucus racemosus (elder).
Spartium junceum.
Spiræa ariæfolia and S. Lindleyana.
Tamarix gallica.
Viburnum Lantana, VV. Opulus and Tinus.
Yucca filamentosa and gloriosa.

AZALEAS MAKE A MOST BRILLIANT DISPLAY OF BLOSSOM IN EARLY SPRING.

Plants for Chalk and Limestone.

In these soils there will be an abundance of lime, and a selection might be made from the following subjects :

Acers in variety.
Amygdalus communis.
Berberis in variety.
Buddleia globosa.
Caragana arborescens and C. spinosa.
Ceanothus azureus, CC. dentatus and Veitchianus.
Cistus ladaniferus and C. villosus.
Clematis in variety.
Cornus Mas and C. sanguinea.
Cotoneaster microphylla and C. rotundifolia.
Cratægus in variety.
Cytisus albus, CC. biflorus, purpureus and sessifolius.
Deutzia crenata and D. gracilis.
Diervilla.
Escallonia macrantha, EE. Phillipiana and rubra.
Euonymus.
Fraxinus (ash).
Garrya elliptica.
Genista.

Digitized by Google

Hamamelis arborea, HH. japonica and virginica.
Jasmines.
Juniperus communis.
Kerria.
Laburnum.
Lavender.
Ligustrum.
Lonicera (honeysuckle).
Magnolia.
Philadelphus.
Phillyrea spinosa.
Pyrus.
Ribes.
Spartium junceum.
Spiræa.
Syringa (lilac).
Viburnum.

Plants for Peat Soil.

As a rule, a peat soil is deficient in lime and, on this account, is not suitable for many

SPANISH BROOM (SPARTIUM JUNCEUM) DOES WELL ON A DRY SANDY BANK.

plants, although some species show a distinct preference for ground of this nature. Here is a list from which a selection might be confidently made:

Andromeda polifolia.
Arbutus Menziesii and A. Unedo.
Arctostaphylos alpina and A. Uva-ursi.
Azaleas in variety.
Ceanothus.
Clethra alnifolia.
Colutea arborescens.
Cornus florida.
Daphne Cneorum and D. pontica.
Epigæa repens.
Erica.
Euonymus.
Fothergilla.
Gaultheria procumbens.
Hydrangea arborescens.
Kalmia angustifolia and K. latifolia.
Koelreuteria paniculata.
Ledum latifolium.
Magnolia conspicua, MM. glauca and stellata
Olearia Haastii.
Pernettya mucronata.
Philadelphus.
Rhododendron.
Skimmia japonica.
Spiræa.

THE DAISY BUSH (OLEARIA HAASTII) IS NOT PARTICULAR AS TO SOIL. *It is free flowering, hardy and easily grown.*

Staphylea colchica.
Ulex europæus and U. nanus (furze).
Vaccineum in variety.
Viburnum.

Plants for Light Sandy Soils.

Trees and shrubs that flourish well in light soils will be found in the following list:

Artemisia.
Berberis in variety.
Ceanothus in variety.
Cerasus (flowering cherry).
Cupressus in variety.
Cytisus in variety.
Elæagnus in variety.
Euonymus.
Forsythia suspensa and F. viridissima.
Fremontia californica.
Genista anglica, GG. pilosa and tinctoria.
Hamamelis.
Hibiscus syriacus
Hypericums in variety.
Hollies.
Junipers in variety.
Kerria.
Laburnum.
Lavender.
Ligustrum (privet).
Magnolias.
Ononis fruticosa.
Osmanthus fragrans.
Phlomis fruticosa.
Pyrus.
Rhamnus alaternus.
Rhus typhina.
Ribes.
Rosmarinus officinalis (rosemary).
Rubus fruticosus.
Ruscus aculeatus (butcher's broom).
Sophora japonica pendula.
Spartium junceum.
Symphoricarpus (snowberry tree).
Syringa (lilac).
Tamarix.
Ulex europæus and U. nanus.
Viburnum.

L. B.

THE DECORATIVE VIBURNUM TOMENTOSUM IS WORTH GROWING IN MEDIUM SOIL.

THE FRUIT AND KITCHEN GARDEN

About Pruning Trees.

THE following are a few hints on the way fruit trees and bushes should be pruned. The work of pruning causes much anxiety to amateurs who have not had any previous experience and find themselves the possessors of fruit gardens. Fruit buds are plumper and rounder than the wood buds and are formed as follows on the branches: on apples, on spurs of the last or previous year's wood; on apricots, on spurs, mainly; on blackberries, near the end of the current year's wood; on red and white currants, on every part of the bush, but mainly on spurs or the side shoots; on the young wood of black currants; on filberts on the sides of last year's wood mainly, some being on the previous year's growths. Gooseberries, on spurs and also on the last and some previous year's branches; on peaches and nectarines, on spurs, but mainly on the young wood of the current year's growth. Pears are similar to apples; plums, on spurs of the last year's wood, mostly. Raspberries should be treated as blackberries. When pruning shoots growing from spurs, all but one should be cut out entirely and the retained shoot pruned back, generally, to two basal buds. Leading shoots are treated in a similar way where the trees are trained on walls or on a trellis and have filled up the available space, but where there is room for extension the leaders should be cut back one-third their length. There are some varieties of apples which bear fruit buds on the current year's shoots—one bud at the extreme point—and as these shoots vary in length from 4ins. to 9ins. or so, they are frequently cut out by the inexperienced grower, thus cutting away practically all the blossom-to-be of the tree. Young trees over-burdened by fruit buds should have some of them cut out the first year or the specimen will not make much young wood for future development. Morello cherry trees bear on young wood of the last season and these young shoots should be laid in at approximately 4ins. apart. If there is any danger of overcrowding, young weakly shoots should be removed, also close attention should be paid to disbudding in the spring. Usually, we leave a pruned base of a shoot bearing three or four buds. Very strong shoots should have more buds left than weak ones. Thinning out is sometimes better than any severe pruning back.—G. GARNER.

Early Treatment of Newly-planted Fruit Trees.

IN practically all cases where cultivators were able to plant their young fruit trees while the soil was fairly dry—before it had become sticky—the soil has settled down firmly around the roots. Specimens that are to be trained on walls or wires may now be made secure to the supports. It is a mistake to plant a tree and forthwith secure the branches to walls or wires, because the tree will be prevented from settling with the soil; the branches are held securely and the soil sinks down, leaving the roots in a suspended position in the soil. In planting young trees a check to growth has been given, so there need be no delay in tying up the shoots to walls as the flower buds will be a little later in opening on account of the check. I am referring to flower buds on newly-planted trees several years old and in cases where the owners wish to have a few fruits the first year. Personally, I do not trouble about fruit the first year, except when I am in doubt as to the variety being true to name, and two years means a long time to wait. Where the soil is of a very retentive nature, refrain from standing on it when engaged in tying up the shoots. It is almost as injurious to put down a long board to stand on unless the board is raised above the soil on two bricks. Young shoots swell freely on healthy trees, so be sure you leave room for the growth of the branches when fastening them to the walls or wires. If tied too tightly, especially in the case of apricots, peaches, nectarines and plums, there is great danger of bruising the bark, when gumming results.—CHRISTCHURCH.

Cutting Down Stems for Grafting.

ALTHOUGH shoots may be successfully grafted when cut direct from a tree at the time when grafting work is being carried out, it is much better to heel-in the shoots in the autumn when the pruning is done. The sap should be more active in the stock than in the graft at the time. It is also wiser to cut down the stems, intended for the grafts, several months before the latter are inserted in them. The edges of the bark on the stems will be thoroughly healed and there will not be any loss of sap at the time of grafting. Before any stems are cut off, you should note their position, the direction in which they are growing, so that the heading-back will be done with a view to forming a good tree in the future. I am, of course, referring to rather large trees with many branching stems and not now to young stocks. A standard or half-standard tree possessing three or four stems forming the head should be so cut down that the stumps of the stems left will be about 9ins. long, this length allows for free insertion of the grafts in the various forms of carrying out this operation. After sawing off the branches, cut the ends of the stumps left smooth with the aid of a sharp knife. Later, if young shoots grow from these old stems, carefully rub them out, taking a small heel of older wood and bark with each one, then there is not much likelihood of more shoots growing. —HANTS.

Growing Early Potatoes.

IT is always harvest time with the gardener, the real, enthusiastic gardener, who tries to get as much as possible out of his garden. Almost before the year's potato crops are stored for the winter months, new "sets" are being prepared for the production of the earliest crop of young tubers. Where there are frames, litter and leaves with which to build hot-beds, and some nice mellow loam, light for preference, potato planting may begin early in the New Year. If no frames are available, the leaves and litter can be utilised all the same. It is not difficult to keep out frost with the aid of dry straw, mats or fern where there is a gentle heat arising from a hot-bed. The planting should take place early in the New Year, but, in the meantime, sprouts are growing on the earliest tubers and the latter should be placed in a box about 7ins. deep and half buried with leaf-soil; then, not only will the sprouts grow, but the roots as well. When the time comes for planting the tubers should be carefully lifted, with leaf-soil adhering to them and planted in the new, warm beds. The new growth will continue steadily. The tubers so treated should not be buried more than 2ins. deep. Later on, a top-dressing of loam and leaf soil in equal proportions should be applied, and this extra soil will cause the young tubers to swell more rapidly. In a frame, atmospheric moisture must be regulated and this can be done by judicious ventilation. In the frame lettuces and radishes can also be grown, but not on the outside bed, because the necessary straw or mat coverings would exclude light. To follow this early crop another one should be grown at the foot of a wall or fence. These are catch crops, of course, but valuable ones where they are well managed. Potatoes may be grown in pure leaf-soil without the addition of loam and manure.

Forcing Asparagus.

EARLY asparagus is always much appreciated. Open air beds yield "grass" early or late, according to the character of the soil, drainage position of beds and the part of the country in which the garden is situated. Thus we see that heat has much to do with the early growth in a natural way and we must provide it, mainly for the benefit of the roots, when we force the growth. Asparagus cannot be forced very satisfactorily in the bed in which the plants grow. The roots must be lifted and replanted in the most suitable quarters. The latter are frames on hotbeds, greenhouses or forcing structures where there is room for hotbeds or where hot-water pipes are available to heat the soil from the bottom upwards. I always found hot-beds in frames and houses answer better than heat from hot-water pipes solely, because the pipes dry up the bottom soil so much. The best time for the inexperienced grower to begin forcing is early in January. In the meanwhile it is necessary to collect materials for the hot-beds and to build them; to collect the soil and sift it. Litter, leaves and any littery rubbish that will, when heaped, engender heat, may be used in the beds in houses or in frames. Shake up the litter and spread it out evenly; do not place it in a lumpy state on the new bed; allow the whole to settle down gradually, without treading, but with the weight of the soil on it. A good bed should be 4ft. high when first built up, then it will settle down to a little more than 2ft. high. The total depth of soil should be 16ins.; 10ins. below the roots and 6ins. above them—above the crowns. Only the lower 5ins. or so of soil should be unsifted, the top layer should be passed through a half-inch mesh sieve, and this soil should be rather dry, then it will close in tightly around the roots. When the top layer has been placed on the crowns, apply tepid water liberally through a rosed watering can. In the case of a frame, close the lights and keep them closed until the first "grass" appears then ventilate judiciously, according to the weather. In frosty weather mats or sacks may be needed night and day to prevent sudden changes of weather causing checks to the growth of the plants in the frames. Even if the soil needs water, do not apply any during frosty weather, but try to keep the soil just moist all through. It is not advisable to force younger roots than those three years old and all crowns selected must be strong, plump ones or the resultant "grass" will not be of any use for cooking, only for placing in vases with flowers. Wherever the bed may be, have it quite ready before the plants are lifted from the borders. Lift them without unduly breaking off the roots, and plant and water before the crowns and fleshy roots have had time to become quite dry. The roots may be planted quite close together.—B.

Planting Horseradish.

LIKE rhubarb, horseradish is often delegated to some out-of-the-way corner of the garden; the roots are planted in badly prepared soil, allowed to become a thicket of roots and leaves and rarely given any detail attention. January is a suitable month in which to plant where light and medium-light soils obtain and the end of

Digitized by Google

the month or early in February in the case of heavy loams. The position should be an open one, that is, an open quarter of the garden. Trench the soil quite 30ins. deep, 3ft. would be better, and loosen the sub-soil below that point. Good, half rotted manure should be buried 18ins. to 2ft. below the surface. Do not place the manure in the trench in lumps, but incorporate it in the soil generally. The reason for deep burying of the manure is to induce the horseradish roots to go down straight and deeply in search of the moisture and nutriment. Select straight roots, young ones, about 9ins. long and place them in an upright position, 1ft. apart in the lined trench. Bury the crowns—single crowns to each root—2ins. below the surface. The rows should be 18ins. to 2ft. apart, as the resultant leaves from strong plants will entirely cover the whole of the space by August next and by the end of the year very fine roots will be available for lifting as required. The only attention needed during the summer is to hoe between the rows frequently to keep down weeds and maintain a loose surface soil.—G. G.

Soil Pests in Winter.

IT is important that the gardener should distinguish between his natural friends and foes. A good instance is to be found in the case of millipedes and centipedes. These strange creatures—which, by the way, are not insects—hide in cracks and under stones, in which positions they are often discovered during the winter. Now, millipedes feed on vegetable matter, such as roots, tubers, bulbs, etc., and should always be destroyed; on the other hand, centipedes live on insects, grubs, worms, slugs, etc., and, to a certain extent, render the grower many a good turn.

The differences between millipedes and centipedes are as follows: Centipedes have long feelers on their heads, while millipedes have much shorter ones. In the case of centipedes the body is flat, but with millipedes it is rounded and not unlike the familiar wireworms. Centipedes are usually reddish brown in colour and have a curious twisting way of moving about; they have twin legs on each segment of the body, that is, one on either side. Millipedes do not twist about so much when they move, and have four legs to each segment or two on either side.

Happily, there are plenty of easy ways of destroying millipedes. Soot or lime, employed as top-dressings or forked into the soil, are excellent. One or other of the well known soil fumigants, like Vaporite or Kilogrub, are sure remedies if the directions given on the packages are carefully followed. Millipedes are particularly likely to lurk in leaf-mould. Here a very excellent method is to pour some carbon disulphide (a tablespoonful to every bushel of mould) right down into the middle of the mound. Protect with sacks and leave for three days. The poisonous liquid will permeat the whole mass and kill millipedes and other pests as well. In the end the carbon disulphide will simply pass off in the form of a vapour.—L. B.

SOME MODERN VEGETABLES WORTH GROWING

TASTE and discrimination in the choice and enjoyment of good vegetables are not, I fear, attributes of the inhabitants of the British Isles, but few will deny the wholesome benefits derived from their consumption.

I suppose that less serious and systematic cross-breeding has been done with vegetables than has been the case with flowers and fruit, and yet, within the memory of most of us, the improvement and development of vegetables have advanced enormously and surprisingly I wonder what our fathers and grandfathers would have said to that superlative exhibit of modern vegetables that was staged by my friend Mr. Beckett at the Royal Horticultural Hall on October 19th this year. I will take it upon myself to go so far as to say that no such fine exhibit of vegetables has ever before been staged, and that nowhere but in Great Britain could it have been staged: that is the great point. Our climate, with all its so-called drawbacks, is, without doubt, eminently suitable for the cultivation of all vegetables, with, perhaps, the exception of certain tropical subjects, and even these offer no difficulties to men with such glass-house skill as Mr. Beckett and some of his contemporaries possess. Perhaps it would be better if I qualified a little the remark I made just now about less breeding having been done with vegetables than with other subjects. I should, perhaps, have said that a greater advance had been made all along the line in vegetables by selection and re-selection of stocks rather than by cross-breeding, for although I am, of course, well aware that a great deal of this latter work has been done with peas, beans, potatoes and certain other things, yet I consider that a great deal still remains to be done in this direction in vegetables generally. Let me give a few instances of what I mean. In lettuces, I should like to be able to find a cabbage lettuce or self-folding cos that tasted like the old black-seeded Bath Cos, for, to my mind, that is the only lettuce that possesses real flavour. I would like to find more of the newer productions in peas with the flavour of Ne Plus Ultra; breeders appear to be working for size alone, without consideration for flavour. Then, again, the tomato should be bred more for flavour than for crop, which latter appears to be the only object at present. To anyone with a discriminating palate, the enormous range of tomatoes now on the market differ in flavour to a remarkable degree, the yellow ones being, as a rule, the most delectable of all, and in this connection I may, perhaps, be allowed to draw attention to one called Orange Sunrise, which I raised some few years ago, and which a number of good judges still tell me they consider the best for flavour.

What applies to tomatoes as regards colour undoubtedly applies also to turnips, for a yellow turnip exceeds in flavour and quality the others, an outstanding example of this being the delicious little root named Golden Ball, a comparatively recent introduction.

The vegetable marrow, in its now numerous varieties, may justly be described as a rather tasteless and insipid thing, but the custard marrow does possess real and characteristic flavour, and some years ago it was my good fortune to hit upon a cross beween this and another variety from which was evolved the little orange-shaped marrow called Rotherside Orange, which I find, both for flavour and shape, seems to be popular with all who grow it.

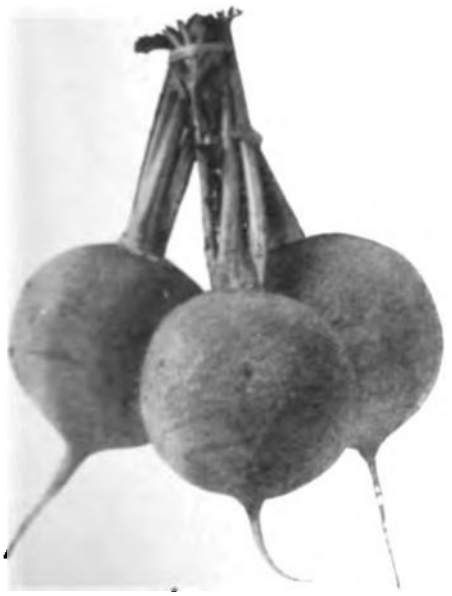
Harking back to tomatoes, I received some seed last year from America of a fruit denominated "Pepper-Tomato," which was claimed to be the result of a cross between the capsicum and tomato: from this seed I raised and fruited a number of plants. I do not doubt that the raiser *tried* to make the cross, but the result of his efforts is a rather curious fruit with no apparent trace of capsicum. It is just to all intents and purposes a tomato, but of a pinkish-purple colour, varying in shape, and a very poor cropper. It has the merit of being firm and very fleshy,

THE NEAT ORANGE-SHAPED VEGETABLE MARROW ROTHERSIDE ORANGE.

and is, I find, excellent grilled with bacon, as a breakfast dish.

Carrots are a vegetable I have not as yet named. When quite young and pulled from an early frame and cooked whole, they are a delicacy to look forward to and enjoy; but later in the season I find there is little demand for them in the kitchen except for flavouring purposes. The little long carrot, Carter's Holborn Forcing, gives good results if sown in a frame as early as November and taken care of. I find the roots mature and are ready for the table about a fortnight in advance of those sown in early spring, not a great gain, perhaps, but I think well worth it.

Broad beans are another crop that we always sow here in November, on the lightest piece of soil we can find on our rather heavy loam, and here also there is a gain in time on the spring-sown ones. Here let me note, and call readers' attention to, a new variety called Sussex Wonder; it has only appeared in the seed lists this year, but I have been fortunate enough to be able to sow and grow it for several seasons past, and for cropping, size of pod and early maturing it beats easily any variety I have yet seen. And let me add that early maturing



SUTTON'S GOLDEN BALL. A TURNIP WORTH GROWING.

Digitized by Google

is, with the broad bean, a very important point indeed. What I mean is this: One notices that, as soon as ever peas come in, very few broad beans are asked for, and Sussex Wonder, sown either in November or early spring, is, at any rate, a good time ahead of the earliest outdoor peas.

Coming to peas, and continuing my remarks on earliness, we find Sutton's Bountiful the favourite here. It gives a large and heavy crop of well filled pods, and the flavour, for a round-seeded pea, is excellent. This pea we sow in December, outside, and, although there is always a certain element of risk in sowing before Christmas, I find on looking through records, that we have had an excellent crop from Bountiful in nine seasons out of ten. In this variety I found a sport some years ago, growing rather taller, and the pods rather smaller and deeper green in colour, but these are almost invariably borne in pairs, and the plants give an immense crop, standing up against any sort of weather, and giving plentiful supplies when other sorts are scarce. For this reason I would not be without it for anything, but I have hesitated to introduce it and send it out, for, very possibly, the same thing may have already appeared and been sent out from other quarters, and there is little use in multiplying varieties in these days unless the article is quite top-notch.

F. HERBERT CHAPMAN.

WHAT OUR READERS SAY

HARDY CYCLAMEN.

SIR,—I note in your issue of December 18th, page 734, that Mr. Ralph E. Arnold has fallen into the error of stating that C. africanum is sometimes known as C. hederæfolium. I would call his attention to the fact that C. africanum is known under the name C. algeriense macrophyllum, and that C. neapolitanum has usurped the name of C. hederæfolium. Many writers have muddled the name of these three varieties. I have in front of me several leading catalogues, and there are not two alike in their description of C. hederæfolium. Reginald Farrer in "The English Rock Garden," Vol. I, writes: "C. repandum has often wrongly been called hederæfolium, a name to be dropped," but he does not state the reason. He gives C. neapolitanum the description of C. hederæfolium. I cannot conceive that C. repandum can be mistaken for hederæfolium, for repandum flowers in the spring and hederæfolium in August, September and October. In my possession there are some old books, and I find the name C. hedcræfolium, but I cannot trace C. africanum or C. neapolitanum. One book dated 1745 mentions autumn cyclamens and spring cyclamens. I use the plural because the book gives it, and to me it appears there were different varieties, most likely C. europæum and C. vernum. I am entirely of the same opinion as Mr. W. Robinson, author of "The English Flower Garden," in his second edition, page 364, where he states the great difficulties of our botanists in clearly defining the species of cyclamen. Another book I hold says Gerard cultivated C. hederæfolium in 1596. In the "Hand List of Herbaceous Plants Cultivated in the Royal Gardens, Kew," 1895, this description is given: "C. africanum, *Boiss & Reut.*, North Africa. C. hederæfolium, *Ait.*, South Europe. C. neapolitanum, *Tenore*, Europe." The authorities there evidently considered there were three varieties. I have come to the conclusion that C. hederæfolium can be traced back farther than C. africanum or C. neapolitanum, and should therefore stand before us as firmly as C. europæum continues to do.

At Croydon we have grown hardy cyclamen for twenty-nine years, and we have raised countless seedlings. In digging up an old bed lately we lifted a corm of C. hederæfolium 9ins. across. I have replanted this giant, and it has started well. It was one of the original corms planted at the time we made the bed twenty-nine years ago, so the age of a corm is great.—MARK MILLS, *Croydon*.

THE RATHER HANDSOME STAPHELIA GRANDIFLORA.

CHRYSANTHEMUMS ABROAD.

SIR,—I enclose two photographs which may interest your readers. The chrysanthemums, a white incurved variety, were picked growing out of doors on November 18th in a bed in the kitchen garden. During August and the first fortnight of September, very little growth takes place, but they develop with astonishing rapidity as soon as the first rains fall and the temperature cools, usually towards the end of September. Even single chrysanthemums, owing to the great heat during the summer months, when the temperature has been known to reach 110 degrees in the shade, never flower before the second or third week of October.

All staphelias do well here, where conditions greatly resemble their native haunts. S. grandiflora is a particularly handsome variety and the odour is less offensive than in many of the family, though sufficiently attractive to flies, which visit the open flowers, deceived by the resemblance of the scent to decaying meat, and lay their eggs, fertilising the flowers in the process.—CHRYSTOPHER SANDEMAN, *Jerez-de-la-Frontera, Spain*.

A NEGLECTED ROSE.

SIR,—Recently some readers of THE GARDEN have drawn attention to certain varieties of roses whose merits seem in danger of being overlooked, and I am glad the Editor has thought fit to publish their remarks. I in turn should like to draw attention to a variety which seems to be neglected unjustly. It is a rose of French origin, with a pretty and well deserved name, Gerbe Rose (Rosy Sheaf). It was raised by Barbier in 1905, and the National Rose Society catalogue says: "Pale pure pink. Climber. Pillar, bush, screen, wall. Dense glossy foliage. Nearly thornless. Large flowers for a wichuraiana. Flowers again in the autumn. Fragrant." That sounds to me cold, official sort of language. I grew it as a pillar in Cheshire some years ago on damp clay soil. It grew with extraordinary luxuriance, sending out so many fine growths I had to reduce if frequently to keep it within bounds. The foliage alone would make it worth while growing: a beautiful bright glossy green, always clean and healthy. The blooms are rather flat and not very shapely, but they come in such quantity and so continuously, are of so good a colour

A BOWL OF DECORATIVE CHRYSANTHEMUMS.

and so deliciously scented that one overlooks the lack of shape, which in any case is hardly looked for in roses of this type.

Wishing to plant this variety in my new abode in Yorkshire, I found difficulty in ascertaining where it could be had. It seems to have dropped out of some of the leading catalogues, but at last I found it advertised in THE GARDEN by a Yorkshire firm. It is a mystery to me why such a splendid rose should be given the go-by. I asked the firm from whom I got my original plant, but got no very clear answer. I think it is perhaps one of those not infrequent cases where the layman or amateur can exercise a healthy influence on the exuberance of the expert. After all, experts raise and propagate roses, and no one is more grateful to them than I, but in the main it is the ordinary folk who grow them on to maturity and often to honoured old age. It is we who know them in civil life, so to speak.

All this prompts me to ask—where are we getting to in the rose world? Perhaps the Editor will allow me a little more space later on.—H. F. J.

THE GARDENER'S LOG [BOOK.

SIR,—Your Editorial of December 4th, 1926, prompts me to suggest the advantages of using the card index system for the garden record. The card index is in very common business use and can, with ease, be adapted to one's garden. It consists merely of a series

Digitized by Google

of cards, which are always kept in alphabetical order. The blank cards are very cheap and can be bought in several sizes from any stationer. Cards tabbed with the letters of the alphabet can be had to subdivide the bulk under letter headings. Each card should have the name of the plant or shrub in large letters at the top and be filed alphabetically.

The system is most elastic. The gardener can give as much space as he needs to any variety of plant. Each variety of, say, pyrethrum, might have a separate card, but each one would, of course, be placed under the heading "Pyrethrum," behind the letter "P."

All comments on any particular plant should be written on its own card. Soil preparation and rotation could have cards to themselves.

Hosts of variations suggest themselves. For my tiny garden all the cards are together, but a large place could have separate files for flowers, vegetables and shrubs; a gladiolus enthusiast may prefer to keep those cards apart from the general record, etc.

The advantages of the method are (1) that it is never finished. As plants are added, cards are put in bearing their names. As plants or strains of seed are discarded the card remains to say why; (2) that the record of years is always present. Instead of having to search through a number of diaries, the behaviour of a plant during several seasons and in varying conditions is under the eye on one or two cards.

The idea has no doubt already been applied to many gardens, but probably other enthusiasts may welcome a simple way of recording their observations. One must be careful to return each card to its proper place in the file, that is the only point to watch.—JAMES W. HARKER, *Durham*.

A NOVEL MUSHROOM BED.

SIR,—Stable manure is very expensive, not easy to obtain and often of extremely uneven quality. In some quarters it seems no longer fashionable to feed horses on oats or hard food, with the result that the would-be grower of mushrooms who has no stables of his own is often faced with failure to a greater or lesser degree when attempting to grow this succulent fungus. Have any of your readers attempted to grow mushrooms on an "Adco" bed; and, if so, with what success? If successful, any hints on the preparation and treatment of such a bed would be of great value.—C. J., *Enfield*.

[We should be pleased if any readers who have experimented with Adco (a chemical material which greatly assists in the decomposition of all garden refuse and transforms it into synthetic stable manure) in this connection will give us their experience. There seems little doubt that this idea of our correspondent could thus be made extremely useful.—ED.]

STORING APPLES ON STRAW.

SIR,—My experience does not confirm your correspondent's method of keeping apples on a dry shelf on a layer of clean straw as by any means the best method of procedure. However clean the straw may be it will undoubtedly communicate its peculiar smell to the apples and, moreover, the dry shelf will hasten evaporation from the apples and soon leave them in a shrivelled condition. For those who have no special facilities for storing apples, I have found far and away the best method is to wrap each apple carefully in soft paper, perfectly greaseproof, pack them in a wood box closely, one layer on the top of another, having first lined the box with paper and then put the lid on and leave them severely alone until they are wanted. It is, of course, essential that only perfect apples be packed in this way; any with even the smallest insect bite in it will go bad. If, however, an imperfect fruit has inadvertently been packed up and goes bad, the wrapping of paper will effectually prevent it infecting any of the others.

In this way I have kept Cox's Orange in perfect condition without a sign of shrivelling until April; other apples have given equally good results.—A. T. MAW, *Leatherhead*.

SIR,—If Mr. H. A. Day wishes to store a few pounds of choice apples until Christmas and has no fruit room, ice house, etc., then why mess about with straw? Why not wrap each apple in tissue paper, they will keep quite well and certainly will not become tainted. Apples sweat and in so doing exude an oil; if this oil touches straw the musty flavour will at once be apparent when eaten. The state of my mind, I am glad to say, is not such that I cannot distinguish between an apple stored among straw and one that is not.—GEO. STUART.

THE MAKING OF LEAF-MOULD.

SIR,—I read in the issue of THE GARDEN for December 18 the correct method for making leaf-mould, and suggest my simple plan to those readers who also run a pen of poultry. From October till after the breeding season is over I run my young fowls in a roofed-over wire netting enclosure. When the leaves begin to fall I fill up this enclosure—4ft. or 5ft. deep—with leaves and add to this from time to time. I fling all grain fed to the birds among the leaves, which make excellent scratching litter. I fork the litter now and again, and by springtime the leaves have all disappeared and I have a beautiful fine mould for my seedlings.—N. F.

TRAPPING MICE.

SIR,—May I suggest that your correspondent should add to his instructions for the trapping of garden mice, the suggestion that the trap should be covered by a box or large flower pot, slightly tilted, to allow free passage to the mouse; but inaccessible to birds. I once set an unprotected trap and caught a blackcap and have never left one open since. I always find protected traps quite efficacious. —ANNIE J. HOBBS, *Lympstone*.

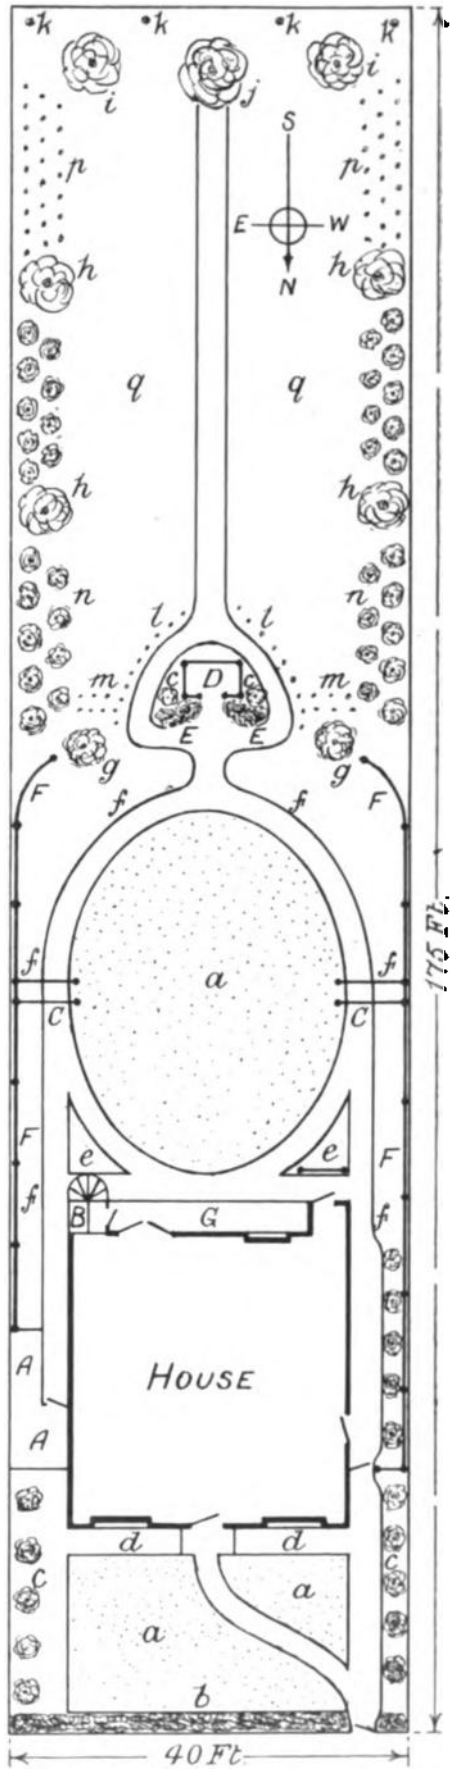
A REMEDY FOR ROUGH HANDS.

SIR,—I was interested in the paragraph, "A Remedy for Rough Hands," on page 705 of THE GARDEN, December 4th. Personally I have discovered a very fine remedy in a hand cleanser called "Adcol." It thoroughly cleanses the hands and keeps them very soft after the grimy toil in the garden and incidentally it contains a harmless disinfectant which cleanses skin wounds. I have also found it a cure for chilblains, if unbroken. Myself I have difficulty in purchasing it. The makers are Alexander Duckham and Co., Limited, of 6, Broad Street Place, London, E.C.2.—G. T. J.

THE DESIGNING OF A SMALL GARDEN.

SIR,—Garden design being the order of the day, I venture to enclose a sketch of my newly formed garden in the hope that it may interest your readers. In working out this design I had two main objects in view, to enclose the garden as much as possible and yet to keep the centre open and visible from the house.

The accompanying design may prove of use to those readers who desire to form an enclosed garden with a fair sized lawn for children to play on, etc. The herbaceous border, with the rose covered trellis at the back, looks very well indeed and a rustic summer house with a thatched roof and small rockeries on either side gives a finishing touch to the flower garden. The whole looks very pleasant from the house. The sketch sufficiently explains the scheme of planting.—L. B. PYCROFT, *Essex*.



A Shed and coal box. B Greenhouse. C Two arches. D Rustic summerhouse. E Two small rockeries. F Trellis or other trellis. G Veranda. a Lawn. b Hedge. c Shrubs. d Flower borders. e Two beds of dwarf roses. f Herbaceous border. g Bush cherries. h Half-standard apple and pears. i Standard plums. j Standard apple. k Loganberries. l Early-flowering cherry and clematis. m Standard lilacs. n Currants. o Gooseberries. p Red berries. q Space for vegetables. The trellis and summer house are covered with climbing roses.

THIS MONTH IN THE GREENHOUSE

The Heliotrope as a Winter Flower.

FLOWERS of delicious fragrance are welcome at all seasons, but never more so than during winter. In this connection one has a word of praise for heliotropes that at one time were more commonly grown for winter blooming, than is the case to-day. Some plants in my greenhouse have now been in bloom since November. In plants for winter flowering buds must be pinched out in summer, and the plants grown on specially for their later value. It is mainly a question of sacrifice and not heat. Just as one prepares cuttings of zonals in spring, and potting on the plants subsequently until, finally, pots of 5ins. are reached, so a similar line may be followed with heliotropes. The same compost suits either, *i.e.*, old friable loam, leaf-mould or spent hops, with a dash of bone-meal, and every flower bud discarded until autumn when plants are removed from frame to greenhouse. It is when heliotropes are so dealt with, and their blooming retarded, that one may count on a show of blossoms in a house the minimum winter temperature of which does not fall much below 55 degrees. Heliotropes make excellent plants for the back walls of lean-to houses, and, if reserved specially for winter blooming, provide quantities of sweetly scented clusters. Planted out in a border within a house, they will soon occupy a desired space if trained out.—CLAREMONT.

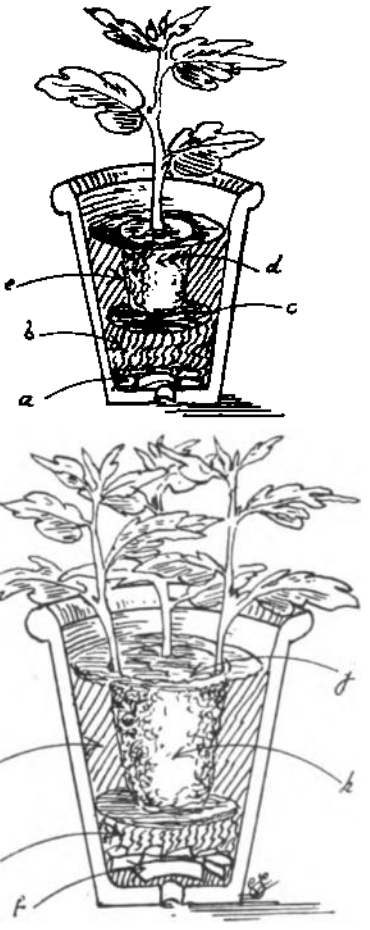
The Cool Orchard House.

IN this country, even in the southern counties, hardy fruits often fail to crop satisfactorily in the open air. They do not require any artificial heat, but the protection of a cold structure, that is, a house unheated, generally ensures good crops if the trees receive proper attention and, in such structures they do require more attention than in the open air with regard to watering, feeding and cleanliness. There is no better time than the present for carrying out certain work, cleaning the branches, the interior of the house, the renovation of borders and the top-dressing of those specimens that require extra rooting soil. The roof of the house should be cleaned first, the glass with clear water, the wood portion with soapy water, any wires existing with paraffin, the trees should then be cleaned, then the walls, the latter being whitewashed and the surface of the borders last, and before any new compost is added to border, pot or tub. After the trees are pruned wash the bark with tepid water and, whether scale or mealy bug be found, wash with a proper strength solution of Gishurst compound, but not touching eyes or buds with the mixture. Surface dressings should be of extra good materials. Fibrous loam, two parts; rotted manure, one part. To each bushel add a 6in. potful of bonemeal and for stone fruits an equal quantity of finely powdered lime. Make all new additions very firm with the aid of the blunt rammer and water at once to settle the new compost further.—G. G.

Potting Chrysanthemums for Exhibition and Greenhouse.

THE successful cultivator of the chrysanthemum decides what to do with his plants right from the cutting stage. If he grows for exhibition and also for procuring great quantities of bloom for cutting or furnishing the greenhouse, he should keep the plants separate from the start. Of course, odd plants, in a very young stage, being a surplus from the collection for show purposes, may be treated differently so as to bear many blooms finally, instead of the orthodox three or so.

From early in January until the middle of February, there will be batches of newly-rooted cuttings that must be potted singly or in threes, as shown in the sketches. The pots for the plants should be selected accordingly so that the shift to each one will be a suitable one. Early potting is essential to success. Never allow a young plant to remain too long unpotted when the roots need more soil to permeate. If young plants are once stunted, their stems, near the base, always remain thin and unduly hard, thus impeding the free flow of sap and nutriment later in the



season. Do not decide to pot up all young plants at once, whether they require this attention or not, but deal with a few at a time just as they do need potting, even if you are potting some several times each week.

Pots and crocks should be clean, of course. The compost need not be of a fancy mixture. Fibrous loam, two-thirds; leaf-soil, one-third, with a nice addition of silver sand or, better still, if available, builder's mortar rubble. A 5in. potful of bonemeal to each bushel of the combined parts is all the manure needed now.

The single plant shown is intended to bear exhibition blooms. At *a* a few crocks only are needed for drainage; at *b* a little of the roughest of the compost; at *c*, this is firmed, the ball of soil and roots placed in position; and at *e* the remainder of the compost is added sufficiently to fill the small pot. The three plants shown should be repotted from time to time, as required, without being disturbed at their roots. At *f* and *g*, drainage and rougher compost, respectively; at *h* the ball of soil and roots; at *i*, the new compost; at *j* the right depth to pot is shown, no new soil being placed over the roots and space is left for effective watering.—GEO. GARNER.

Begonias Under Glass in Winter.

THE great masses of flowers, borne by the winter-flowering section, are greatly appreciated at a time when the weather is, mostly, dull and cold. In the opening year there are few kinds of available flowers—even those from bulbs—that afford a more pleasing and brilliant display. The foliage of Begonia Rex is, too, a charming feature in the warm greenhouse. A glass structure with a summer temperature is ideal for both plant leaves and flowers. Then it is necessary to pay close attention to the atmospheric conditions and the watering. Feeding is not necessary as stimulants should be applied while the plants are growing and the pots filling with roots after the final potting. Excessive moisture and a low temperature spoil the flowers and often cause the leaves to damp at the joints and fall off. The winter-flowering plants do not possess tubers, but very swollen or thickened root stems and great numbers of fibrous roots; so we see how necessary it is to be careful as regards atmospheric moisture and water in the soil at this season. Probably Begonia Gloire de Lorraine, pink; Turnford Hall, blush; Elatior, rosy carmine; Emily Clibran, orange-salmon; Winter Glow, bright red and the hybrids resultant from the Socotrana crosses are the general favourites. Plants of the last-named class possess larger leaves and flowers than those of the Gloire de Lorraine class and are more susceptible to damp. In a short time, now, the flowering strength of the plants will fail and then they should be allowed to dry off a little at the roots and be subjected to a slightly lower temperature. A shelf about 2ft. from the roof glass will be a suitable position for them until the very early part of spring, when the influence of more moisture and a higher temperature will induce the growth of basal shoots suitable for propagation.—CHRISTCHURCH.

Sow Tomato Seed Now.

GROWERS who have special facilities, as, for example, a suitable greenhouse, a good source of heat and time to attend to the work, may raise tomatoes in December, but most people do not make their first sowings until January. The lack of sufficient daylight is a drawback with early sowings, for it is very difficult then to keep seedlings short and sturdy. It is always a wise plan to prepare a good compost beforehand. I am a firm believer in the efficacy of sterilised soil and, as has often been pointed out, sterilisation is best carried out some time in advance of actual needs. The compost must not be a rich one; good loam is required, a little sand and, perhaps, a little leaf mould, well rotted. At this time, however, seed must be ordered—and this is probably the most important point in tomato growing. Good seed, seed saved from pedigree and healthy plants, is distinctly essential—seed from a source that has proved itself reliable in past seasons. Good seed may cost more, but it is cheap at any reasonable price. Sow it when the correct time is determined on; seedlings will appear in a week and these may be got into small pots, deep down, as soon as they are a couple of inches high. He would be a daring man to list the "best" varieties; really there are many first-class kinds to be had and the difference is very small. Let us name a few—a good catalogue or catalogues will describe them—Market King, Sunrise, Selected Ailsa Craig, Matchless, Devon Surprise, Champion, Leigh Park, Everyday, Best of All, Aldowrie and so on.—LANARKSHIRE

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Damping in Frames.

Apart from the continual rain and sunless days, this season generally brings much fog and to all who have frames of various plants, such as lettuce, cauliflower, etc., damping off is one of the worst things to contend with. A quantity of unslaked lime, however, about the size of a coconut, put in a flower pot or small box and placed under each light will be found to absorb all the moisture which would otherwise settle on the plants. This answers the same purpose in a greenhouse where chrysanthemums are grown, firing being clear at this time and not a necessity.—C. E. J.

To Obtain Skimmia Berries.

Most garden lovers know that, owing to the unisexual nature of the flowers of Skimmia japonica, an isolated plant of this species cannot produce berries without artificial fertilisation—an operation which busy people generally overlook. It is not generally known, however, that by planting S. Fortunei, an equally attractive species, it is neither necessary to purchase male and female plants, nor to fertilise the flowers by hand, for every plant produces its crop of berries annually without the intervention of the gardener.—A. J. I.

Failure of Clematises.

When large-flowered hybrid clematises are planted against a hot, sunny, south wall, trouble often ensues if the sun is allowed to beat upon the base of the plant. Weak puny growth that is apt to shrivel and collapse is the usual form the annoyance takes, and often the plants will die off altogether in a year or two.

To obviate this nuisance, assuming, of course, that other conditions are favourable, moderately tall growing shrubs or perennials should be planted in front of the clematises. The benefit of the shade thus given is soon apparent, and strong healthy growth, with abundance of blossom, is the natural result.

We were troubled in just this way for two or three years, but since providing shade we have had no further difficulties. Curiously enough, C. montana, planted at the same time and along the same wall as the Jackmanni hybrids, forged ahead without the least check, and has long since reached the top of the house. Probably this and similarly vigorous species are immune from the trouble as they develop woody bark-protected main stems.—B. D. S.

An Efficient Method of Manuring Runner Beans.

This method I have found successful for many years. Choose the required position for the current year's sowing. Dig out a trench 2½ft. to 3ft. deep and 18ins. wide. Use this cavity all the winter for garden rubbish, such as leaves, old greens, even the stems of Brussels sprouts and household refuse may be deposited. Sprinkle with lime at intervals. When spring comes, fill in the trench and sow the beans in the usual way, a dusting of superphosphate at that time being beneficial. The trench proves a useful dumping ground and also provides in due course the necessary humus required for the roots of the bean plants to feed on. Pea trenches may be treated in the same manner.—S. H.

A Good Way to Get Early Peas.

Take some rough turf, cut it into strips about 6ins. wide and about 1½ins. to 2ins. thick. Turn the turf so that the grass is at the bottom. Then take a small dibber and make the holes big enough for a pea to go in, making three rows in each turf and 3ins. between each pea in the rows. Place in a cold frame and when the seedlings are about 6ins. high harden off and plant out. When planting, draw out a drill as if for potatoes, seeing that it is even at the bottom. Take the turf containing the peas and place it along the drills, then draw the soil up so as just to cover the turf. I find that the Pilot pea is the most hardy. A good time to sow is about the middle of January.—E. M. H.

An Economical Means of Using Lawn Sand.

Owing to the price of lawn sand, I find the following method most economical: Mark off with a garden line a strip 6ft. wide of lawn and with a large cocoa tin (1lb. tin) filled with lawn sand squeeze the tin so as to form an oval shape and just drop sufficient sand on each weed. Follow with successive strips until the whole lawn is dealt with. It is surprising how far a hundredweight of lawn sand goes if used in this manner.—A. W. M.

Forethought When Planting.

When forming plantations of trees and shrubs, it is always advisable to look into the future and allow of ample growing room. This is neglected in many gardens owing to the craze for immediate effect. When ample room is allowed good use can be made of the section planted with trees, in that, to form an undergrowth and to protect the shrubs, many varieties of cuttings can well be grown without difficulty. What shade is afforded by the trees will serve to protect the cuttings during the dry spell of their first summer. I have found that all varieties of poplar, willow and dogwood do well, while Buddleia variabilis and B. globosa, philadelphus, deutzia, ribes and elders are just a few of many others that can be treated successfully in this way. The advantages of this method are that the ground is fully occupied by permanent trees and by cuttings which after one or two seasons' growth may be lifted for planting elsewhere. In the meanwhile extra protection is afforded to the young shrubs by the growths of the cuttings.—R. B. H.

PROTECTION FOR GARDEN FRAMES

The Brick Frame.

THE garden frame may be termed the miniature greenhouse; it is a valuable asset, of which great care should be taken. Throughout the summer months it is only necessary to put on coverings to screen the plants from the sun's rays. But from November to mid-May coverings are needed, not only to exclude frost but also cold air and damp. If a frame is kept closed and covered for a considerable time the plants inside will suffer from excessive damp. But it is a fact that occasional covering with mats, bags or sacks will exclude fog and atmospheric moisture when the air is heavily charged with it. I strongly advise cultivators to use their discretion and put on the covering material at such times even when there is no likelihood of frosts occurring.

Brick frames are better than wooden ones for preserving plants during a severe winter because of the thickness of the walls, and, as frost strikes downwards, the owner of the frame or frames can concentrate on the top covering mainly. Frost follows air, so that one must be careful about the close fitting of the glass lights and see that the wall-plate fits well on the brickwork, and that the mortar is sound immediately under it. It is good policy to form a mild hot-bed against the walls in cases where any plants or vegetables are being forced. Strawy litter, freshly gathered leaves and old grass, the trimmings of banks and rough ground should be mixed together and piled against the walls of the frame. A mild heat will be engendered which will keep the walls warm and also the air immediately around the frame. I have used such materials for this purpose and seen the snow melt as it fell on the bed. With a mat placed directly on the glass and on the mat a foot-deep layer of dry litter 20° of frost can be excluded for two or three weeks. This is of considerable importance where there is tender growth inside the frame, which would perish if frosty air gained access. It is of the utmost importance, too, that all protecting material be kept dry. Litter, when on the frame, should be carefully raked straight down to form a thatch and thus convey most of the water to the ground, then the under layer will remain dry.

Wood Frames.

These are more common in gardens than brick ones; few of the latter are built now. The same principles can be applied, however, as in the case of brick frames except in regard to forming mild hot-beds against the walls. The heat and moisture combined would soon cause the wood to decay. But I use a lining, nevertheless; it is one of quite dry litter, which does not engender heat. The perfect covering for a wood frame—which, by the way, should not contain plants as tender as those in a brick frame—is one used as follows: Large, dry mats or sacks are first placed on the glass lights with their ends well extending over the sides of the frame, then a layer of dry litter and, finally, mats or bags on the litter. A few rather heavy sticks or boards placed on the mats will prevent the wind blowing them off and the straw too. Sometimes winds do in the night dislodge the covering material and then frosty air enters and kills or harms the plants. Furthermore, the mats keep the litter within bounds and tend to general neatness. Always put on the coverings, in case the nights are likely to be frosty, before the sun sets—one hour approximately. Do not remove the material too soon the following morning when frost occurs only during the night. Wait until the temperature is about 6° above freezing point.—G. GARNER.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumtances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Sowing Gardenia Seed.

I have been sent some seeds of gardenia from South America. They are hard, oval fruits about the size of a nutmeg. Will you kindly tell me if they should be planted whole, or how? Also in what soil and if now or in the spring?—A. G., Freshwater, I.-of-W.

The hard wood fruits of gardenia should be broken open before sowing the seeds. You can sow them now as they usually take a long time to germinate, sowing them in light, sandy soil, such as you would use for most seeds. After sowing, the pots should be plunged in a warm propagating case with plenty of heat at command. There are, of course, quite a number of species, most of them native of South Africa, China and Japan.

Establishing Mistletoe on Oak.

I want to graft mistletoe on an oak tree and I see in one of my bound volumes of THE GARDEN *that full directions are given; these I will follow. But it says, "Sow the seed on a bough three or four years old"; as the oak tree is fully grown, I cannot do this. Do I stand a fair chance of succeeding, if I sow the seed on an old bough of the oak? I have excellent mushrooms this year in a field and a few days ago I found them on a heap of old grass with sand and leaves mixed with it. Ought I to keep this patch undisturbed for another year or can I transplant it—so to speak—to another part of the field, so that I can dig the rest of the heap of rubbish into the garden? Owing to some slight alterations which I am making to my rose garden, I find that many of the roses will need transplanting and, incidentally, that some of the beds will have to be drained. The roses have been in their present positions for six years and I want to know if they will transplant successfully? I should like to say how much I enjoy your paper and what valuable hints I get from it.—E. N. C., Buckhurst Hill.*

The three or four years old oak branches are preferable, but older ones may be selected for sowing seeds of mistletoe on. Sow the seeds at the end of February, when they will be sufficiently ripe, in slits of the bark on the underside of the branch. Wrap some thin muslin over the branch and seeds, to protect the latter from the birds. Keep Christmas mistletoe berries until that time—February—in a cool, dry shed, retaining them on their branches. Mistletoe grows best on apples, poplar, mountain ash, thorn and lime. You may succeed with the mushrooms if you remove the heap carefully in large lumps to a well drained part of the field, but the mycelium may perish if disturbed now. It will be quite safe to transplant the roses now.

Camellias in the Open.

About fifteen years ago I planted out in an old sandstone quarry a small camellia from a pot. It has grown well, till now. It is fully 4ft. high and a fairly large size round. Up to the present it has never bloomed, but this summer I find it covered with large and healthy flower buds. Will you kindly inform me whether the bush should have any protection during the coming winter, and if so, whether it should remain covered or have the covering removed from time to time? I think my recollection of camellias at the Italian lakes and elsewhere is that they remain covered the whole of the winter, but I am not sure of this.—E. M. A. H., Lichfield.

The great difficulty with camellia culture in the open air is this country is that, though the plants are perfectly hardy, they flower in winter and early spring, being invariably damaged, if not destroyed, by frosts. The best arrangement is to fix up a light skeleton framework of wooden battens surrounding the plant, and over which frigidoma or some similar cloth covering can be placed during frosty weather. Remove the covering during mild spells, and, if possible, for a few hours in the middle of the day when the nights are cold.

A Lettuce Pest.

Early this summer a plague of small beetles attacked my lettuce beds. They demolished completely every sign of a lettuce, went on to the parsley and demolished that, and so on to thyme, tomatoes and dahlias, of which they only attacked the flower. They smothered in all about a quarter of an acre, doing great damage to other things beside the above, such as seedlings of cabbage, cauliflower, etc. I tried various washes, etc., without success. I showed the creatures to many local gardeners, who had never seen such things and could not help me. The beetles have a long proboscis and are about as large as a large flea, black and fairly hard. Can you tell me what these are and how to get rid of them?—G. A. H.-Y., Yoxford.

Judging from the description which you give of the small beetle-like insect, it is probably one of the phyllotreta, perhaps P. concinna. They are allied to the turnip flea beetle and do a great deal of damage to crops. All weeds, especially charlock, should be cleared off the ground and as much autumn tilling of the soil done as possible. Winter dressings of lime and summer dressings of soot keep down this insect considerably, also paraffin emulsion sprayed finely on the crops. The poorer and drier the soil, the more the pest attacks the crops.

Unhealthy Vines.

I am writing to ask if you will, through your paper, THE GARDEN, *give me some advice what to do with the Black Hambro vines here. They are quite all right as regards foliage and wood and they set quite well and stoned, but many of the berries neither swelled nor coloured properly, but turned quite red. The border is an inside one and I think the drainage is all right and the vines are not old, planted in 1923. I was wondering if lime would do any good as there is none in the soil here. If you can help me in any way I should be extremely obliged to you.—A. O. S., Mallaig.*

Young vines do, sometimes, behave in the way yours have. Undoubtedly some lime and lime rubble, mixed with the surface soil and watered in during the autumn, would prove very beneficial. Two or three ounces of bone meal per square yard would also do good. But your young vines may be over-cropped; if so, the berries would fail as you state; they even shank at this early stage. Attend to the watering in due season, avoid over-cropping, take care of the main leaves, allowing them room to grow in and get the wood thoroughly ripened.

Weeds on Lawns.

I have recently had a lawn made by a local firm of nurserymen gardeners, but find the turf full of weeds, as enclosed root. I have already pulled out several bucketfuls, but if I keep on pulling it out the turf will be spoilt, as there is so much of this weed impregnated in the turf. Can you tell me if the weed will die off during the summer if I keep the lawn cut close? The lawns here burn up in the summer through having no depth of soil. My garden was virgin sand six months ago. All the soil has to be imported.—G. F. H., St. Anne's-on-Sea.

It is unlikely that the weed in your lawn will be destroyed by the use of the mower, although constant cutting will undoubtedly weaken it. Docks, of which the weed appears to be a species, are rarely troublesome in lawns, but when they do appear they can be totally eradicated only by cutting out the roots. Have the weeds spudded out periodically.

Manure for Asparagus Beds.

I should be very glad to receive information as to the best manure to put on asparagus beds. My beds have been for years annually dressed with seaweed only. The result generally is a good quantity of very spindly "grass," and I should like some bigger and fatter growths, such as grow in the neighbourhood. I propose getting some agricultural salt this year and also some manure of a suitable kind. Some of the beds are old beds, and one was made three years ago, with three year old roots, which were said to be of the large variety.—L. T., Bembridge, I.-of-W.

The nutriment contained in seaweed is good, but not very lasting. Some light farmyard manure, applied now, as a top-dressing, and removed in March, would help Established beds can be improved wonderfully by feeding with diluted liquid manure during July and August—two soakings each week. The agricultural salt, judiciously applied, will be beneficial, too. Avoid over, and late, cutting.

Alpines for a Greenhouse.

I want to grow about twelve varieties of alpines in my greenhouse. They must be varieties and preferably of good botanical interest. Your suggestions would be much appreciated.—W. L. C., Birmingham.

With reference to varieties of alpines to grow in your alpine house, we should suggest a few of the following: Saxifraga Grisebachii, S. lilacina, Tecophylæa cyanocrocus, Dryas octopetala, Primula Winteri, P. Veitchii, P. Forrestii (Omphalogramma vincæflora), P. Chionantha, one or two of the meconopsis, one or two dwarf irises, Campanula Allionii, C. Zoysii, Androsaces, such as sarmentosa, villosa, carnea, one of the Celmisias from New Zealand, Eritrichium nanum (very difficult), Oxalis enneaphylla, and Shortia uniflora. From these you should be able to make a choice collection.

NOTES OF THE WEEK.

Disease Among the Hyacinths.

DURING the growing season of 1926 Dutch bulb growers have experienced a widely spread and disastrous epidemic of disease among hyacinths. Hyacinths have been grown commercially in Holland for two or three hundred years and probably during all this time the disease has been known, but it has been held in check by planting the bulbs each year on land which has not been occupied by hyacinths for several years. During the war, growing stocks were reduced to a minimum and resulted in sensationally high prices being charged. This, naturally, led to a rush of production. Hyacinth bulbs of saleable size take three or four years to grow and there is very little doubt that land has been, in many instances, kept in hyacinth cultivation and used over and over again, with the result that disease has sprung up on every side. Very few, if any, Dutch growers of importance grow all the bulbs they sell; none can claim stocks entirely free from infection and, as the disease cannot be detected in dormant bulbs without destroying them, they may buy in good faith but with disastrous results to the purchaser. Holland is blessed with richly fertile soil, and the skill and industry of her horticulturists are well known, but there is little doubt that there is a very widespread laxity in regard to diseased stocks and the disposal of affected bulbs. It is only fair to add that Dutch exporters of repute are deeply concerned with the present widespread outbreak and have suffered extremely heavy losses in the endeavour to stamp it out. There is at present no known cure for hyacinth disease. Its progress is rapid and is evidenced by the flower spike rotting within the bulb. The spike appears sometimes to grow an inch or so and then stop. On examination it will be found like a loose tooth and pulls easily out of the bulb, the lower end being a mass of rottenness. If you have the misfortune to find this trouble in your bulbs, do not hesitate to take the matter up with your dealer.

Information giving particulars of the date of purchase and source of origin of the bulbs is of interest to the Ministry of Agriculture, Whitehall Place, S.W.

The Temptation to Sow Old Seeds.

SEED lists, which are beginning to be circulated, remind us that shortly it will be time to decide what seeds we shall order for the coming season. In all probability, some of us at least will go to a certain drawer or box and there find remnants of last year's supply, and—perhaps for the sake of economy—we shall say to ourselves "it is a pity to waste it," and begin to debate within as to whether some of these old seeds cannot be turned to good account. In a word, "whether they will do." The questions which naturally arise are these:

(1) Are we ever justified in using old seeds in preference to buying new?
(2) Supposing they germinate, will they give just as good results as fresh seeds?
(3) Is it a paying proposition to make shift with old seeds?

These are questions which cannot be answered in the negative or affirmative without qualification, as so much depends upon the variety of the seeds and, incidentally, the source from whence they were procured.

Experienced gardeners have no hesitation in saying that, speaking generally, it is unwise to sow seeds kept over from the previous year without first subjecting them to a test, as it is well known that some hold their vitality much longer than others, which cannot be depended upon. In the case of brassicas—Brussels sprouts, kale, cabbage, for instance—while one sometimes finds their germinating power little diminished, "softer" seeds, such as parsnips, parsley, beet, celery, fail in the test. Again, in the case of flower seeds, the same difference will be experienced. Stocks, primulas, lobelias, asters, mimulus, helichrysums and rhodanthes may be instanced as having little "staying power," and should not be depended upon without first applying a test. On the other hand, seeds like sweet peas, balsams and wallflowers have been known to retain their vitality for a year or two.

Testing Seeds.—If one proposes sowing a bed, say, of carrots in March, it would be unwise to rely on old seeds unless, a few weeks before, a sample of the seed had been sown in pans in the warmth of a house or frame to test their vigour and germinating power.

Things that Matter.—After all, what is it that the average amateur gardener really needs? It is a fact that he requires very little so far as *quantity* is concerned—then why run any risk? Many gardeners do not believe that, supposing old seeds do germinate, the plants which are the outcome are as strong as those from fresh seeds! It seems to us there are three cardinal virtues in connection with the purchase of seed which the buyer would do well to bear in mind. They are these: quality, purity and freshness, and we submit that the last is as important as the first.

HAVE YOU

¶ *Dug and manured all vacant flower beds?*
¶ *Pruned and cleaned your late vines?*
¶ *Repaired the edges of your lawn and grass walks?*
¶ *Propagated your perpetual carnations by striking cuttings in a warm greenhouse?*
¶ *Lifted and stored in a cool cellar a quantity of Jerusalem artichokes? These will be ready for use during rough weather.*
¶ *Cut back decaying or overhanging branches of your deciduous trees?*
¶ *Examined your dahlia roots, gladioli corms and begonia tubers which are now in store? Diseased or rotting specimens should be removed.*
¶ *Washed and graded all dirty flower pots, and repaired and made new seed boxes?*

Secretaries of Horticultural Societies.

WE would again ask secretaries of horticultural societies who may not have seen our notice of December 25th last to send in to the Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2., a list of their meetings and shows for the coming year. In this way we shall be able to print week by week a complete diary of events in the horticultural world.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 6, which appeared in our issue of December 25th, have been awarded to

Mr. C. Brooke,
2, Overhill Road, Purley,

and

Mr. Charles Pine,
7, Villiers Road, Oxhey, Watford.

To each of whom a cheque for that amount has been sent.

We are indebted to Messrs. Sutton and Sons of Reading for the use of the illustration which appeared on the front cover of our last issue. It shows a group of hollyhocks growing in their trial grounds at Reading.

A NEW YEAR'S NOSEGAY

Even during the winter months there is no reason why there should not be some colour in every garden, though, naturally, winter flowers will be more numerous in favoured situations.

MANY amateurs seem to lose interest in their gardens during the winter months. The fact that some of them—the wage earners—practically only have a chance of seeing their gardens at the week ends may in some measure account for this. It is, however, surprising how many different flowers one may cull to form a New Year's nosegay, if the small garden is carefully planned.

On the wall or climbing over the porch the winter jasmine is in full flower, displaying its bright yellow spikes and mingling with the winter-flowering clematis (C. calycina). This is a native of Minorca and Corsica and in this country is better for the shelter of a wall. Not only are its large yellowish-white flowers very handsome, but the leaves turn a beautiful bronze colour to set them off to even better advantage.

The delightful little yellow bells of Forsythia suspensa may not open quite so early in the year, but there is the pleasure of watching the buds and waiting for them to open on the long leafless shoots.

In a sunny sheltered spot the winter-flowering honeysuckle (Lonicera fragrantissima) perfumes the air with its insignificant, but numerous little flowers. This was introduced from China by Fortune and, like the forsythia, flowers before the leaves appear.

Another shrub with deliciously scented flowers is the winter sweet (Chimonanthus fragrans). The flowers of a brownish-yellow, decorated with purple inside, are likewise produced on the bare leafless stems. If possible it is best to afford it the shelter of a south wall.

The laurustinus, or to give it its correct name, Viburnum Tinus, must not be forgotten among these rarer things, for, though it is so common, there are few shrubs that that are more beloved than this old garden favourite. Among the very much smaller shrubby plants the daphnes must take first place. Daphne Mezereum, with its bare woody branches clustered with its pink or white fragrant flowers, which do not attain their full beauty till a little later in the year, may, however, be counted on to open a few flowers here and there. The other daphne (D. Laureola), which flowers somewhat later, is, like Mezereum, a native shrub. Though not a showy plant, its green flowers are half hidden under its dark glossy leaves; it is of interest, for it was held sacred to Apollo. Ovid tells us how Daphne, the daughter of a river god, was turned into a laurel in order to avoid the pursuit of Apollo.

The neat little bushes of Skimmia fragrans will be in bud at the turn of the year, even if they do not open their fragrant white flowers till somewhat later. They hail from Japan and the sexes are on different plants, so if berries are desired, both the male and the female must be planted in close proximity.

Of smaller plants which can can be relied upon to enrich our New Year's nosegay, there are quite a number. The violet, which comes up so bravely even after a severe touch of frost; the polyanthus, with a stray bloom here and there; the primrose and more especially the blue primrose; the Christmas roses in variety; violas, and here I must make special mention of a winter-flowering pansy. Sown about August and pricked out when large enough to handle, this pansy will make fine plants by the time winter sets in and will furnish a succession of brightly coloured flowers throughout the winter months.

Then there is the Algerian flag (Iris stylosa, or unguicularis as it is now more properly called), growing at the base of a south wall and producing its lovely pale mauve, blue and white flowers half hidden in the long, grass-like leaves. If these are cut when they are still in bud and placed in a vase of water in a warm room, the flowers will be spotless and quite unblemished. I. stylosa makes a most effective house decoration, and yet one rarely sees it used for this purpose.

There are many dwarf iris species which are likely to be in flower at this early season. I. Histrio, a charming species from Palestine, is an early flowerer; and the winter-flowering crocuses, such as C. Imperati or C. Sieberi, may be showing bloom.

Galanthus Elwesii, an early-flowering snowdrop, is a dainty flower for a New Year's nosegay, and nestling at the foot of an old tree one of the hardy cyclamens may be carrying a few flowers.

Of bulbous plants one may look for a snowdrop or two, the winter aconite, with its pretty green collar and the great autumn daffodils (sternbergia), which will still be in bloom.

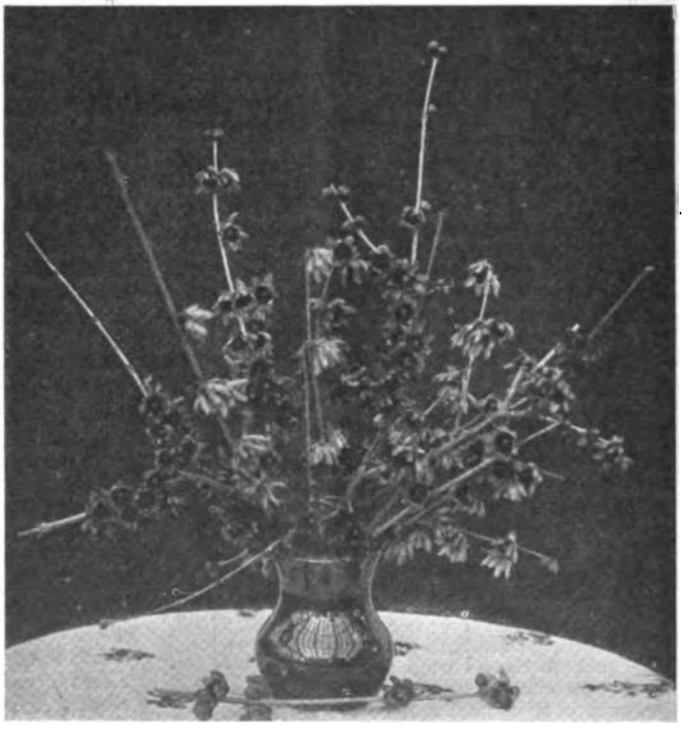
Lungwort (pulmonaria) should at least be showing buds, if not a stray parti-coloured flower. The double perennial wallflower, known as Harpur Crewe, should also be opening its buds. One is sure to be able to find a late marigold and perhaps a lingering red-hot poker.

On the rockery there are certain to be a few what we may call freak flowers. A big blue cup of Gentiana acaulis, a few blue stars of the training stems of Lithospermum prostratum (Heavenly Blue). The self-sown seedlings of the violet cress (Ionopsidium acaulis), which was sown last spring, will, as likely as not, be flowering again.

Perhaps I have named sufficient winter-flowering shrubs and plants to awaken the interest of the enthusiast of the small garden, but doubtless there are many more that could add colour and fragrance to our New Year's nosegay.

EDWARD CAHEN.

THE SWEET SMELLING BLOSSOM OF THE WINTER-FLOWERING HONEYSUCKLE.



THE WINTER SWEET (CHIMONANTHUS FRAGRANS) IS AN OLD FAVOURITE.

FLOWERING CLIMBERS FOR HOUSE FRONTS

Useful hints for clothing the house front, a problem that puzzles many gardeners who wish to have colour on their walls for at least a month or two of the year.

THE charm of flowering plants covering the walls of so many English homes is a source of comment from visitors abroad, and calls forth not infrequently much praise. The practice of enveloping walls with creepers and climbers is on the increase, and in certain districts we know there has sprung up a friendly rivalry in this direction. That plants beautify the walls of a house, making the most unpretentious dwelling very attractive, there is no gainsaying, and the best of it is, there is scarcely a wall where it is not possible to grow something that will bloom. At the risk of appearing prejudiced, we are of opinion that scarcely any flowering creeper has become more popular than various forms of the clematis, notably those in the Jackmanni and lanuginosa groups. Whether the wall to be covered is facing south or east, one cannot go wrong in planting these prolific blooming plants, and, when once established, they will improve as the years go on. But there is no lack of variety in the selection of suitable plants for the covering of any house. Roses were never more popular than they are to-day, and certainly there were never so many sold. Ramblers continue to enjoy a large share of patronage; American Pillar, with clear pink clusters, is to be seen everywhere; Albéric Barbier, with deep glossy foliage and creamy yellow buds and blossoms and Paul's Scarlet Climber are representative of the Wichuraiana group, while the old-fashioned Gloire de Dijon has countless admirers. Another useful climbing rose is R. sinica Anemone. For draping a house wall during May it is hardly possible to conceive a more beautiful subject than the old Wistaria sinensis, with its long racemes of blue flowers.

ROSE SINICA ANEMONE ON A HOUSE FRONT.

Another hardy climber, which seems now to be receiving much more attention, is Polygonum Baldschuanicum, noted for its exuberant growth and its myriads of white flowers, which are succeeded in autumn by red fruit. Another member of this family is to be found in P. Aubertii, stronger and more vigorous than the preceding, also producing masses of white flowers.

Two yellow-flowering shrubs that are not always associated with climbing plants, but which are quite amenable for training, are forsythias and kerrias. In the former, we have Forsythia suspensa, the blossoms of which appear some time before the leaves, and if this is planted on a south wall one may have its beauty in the early year. Kerria japonica, more often met with as a bush, is also suitable for a wall or a doorway and, trained out, will envelop with its pleasing foliage and orange yellow double blossoms in early summer. Handsome, both from the point of view of a flowering climber and for its immense laurel-like leaves, few things are more beautiful in their season than magnolias, and, for a sheltered position and a south wall, one could not have anything more attractive. M. grandiflora has large white waxy flowers, sweetly scented. M. conspicua, also white, bears blossoms in the greatest profusion in early May, if planted in a sheltered place. More consideration is being given to climbers on house fronts, that have a certain value for their flowers, but the chief charm of which lies in the berries or fruits which follow in early autumn. One such will suffice: it is the pyracantha, and the several members of the family have each a claim on the would-be planter for autumn effect. P. Lalandei bears, in summer bunches of hawthorn-like flowers followed by brilliant scarlet berries. P. crenulata has orange scarlet fruit; while P. Rogersiana, a comparatively new sort, yields orange red berries. All the pyracanthas are serviceable for planting at the foot of a north wall. They are evergreen.

Ceanothus azureus Gloire de Versailles is a beautiful shrub which can be trained up a house front. It bears clusters of rich blue flowers during the early summer, and is quite easily grown, succeeding in most districts. Cydonia japonica is well known as a wall shrub. There are several varieties of this shrub, but the most commonly grown is the scarlet-flowered variety. The best clematises to plant are the white-flowered montana, and, of the named varieties, Nellie Moser, silver white tinged with mauve and splashed with carmine rose; Prince of Wales, a deep bluish mauve with a satiny surface; King Edward VII, a beautiful violet; Queen Alexandra, large pale lavender flowers; Belle of Woking, double, silvery grey; Albert Victor, deep lavender; and Duchess of Edinburgh, a free-flowering, sweetly scented double white.

A MAGNOLIA THAT IS ALLOWED TO GROW FROM A SHADY POSITION UP TO THE SUNLIGHT.

Planting and Soil Preparation.—As weather serves, one may plant the subjects named at the present time. Due regard should be paid to the fact that, as they are intended as a permanency, more than ordinary care should be taken in providing suitable soil—loam for a basis—removing rubbish, which is so often found close to the foot of a wall, and substituting two or three feet of rooting material.

Climbers that are Self-Clinging.

THERE are not a large number of hardy climbers that will cling to a bare wall by means of stem roots or tendrils. Of course, in the forefront of the self-clinging climbers will be found the ivies and, indeed, in many situations, these can hardly be equalled. Some varieties of ivy cling more freely than others, but the majority will usually get a good hold when they are well established. Some ivies will grow where little else would succeed, and in an unfavourable situation there is nothing to equal the common large-leaved Irish ivy. This will grow almost anywhere, and it is easily kept in check by hard cutting in the spring. Other green-leaved ivies which are good include algeriensis, amurensis, atropurpurea, Caenwoodiana, corrugata, crenata, deltoidea, dentata, digitata, himalaica, minor, sagittæfolia and venosa. These varieties differ in the sizes of their leaves: for instance amurensis and dentata have very big foliage, while Caenwoodiana and minor have extremely small leaves. Silver and golden leaved ivies offer attractive forms. Good variegated silver-leaved sorts are to be found in marginata media, Crippsii, marginata rubra and maderiensis variegata. Some fine golden forms include aurantiaca, aurea elegantissima, chrysomela, chrysophylla, flavescens and palmata aurea. Practically all the ivies benefit by hard pruning in the spring.

After ivy the most important self-clinging plant is the well known Ampelopsis Veitchii

Digitized by Google

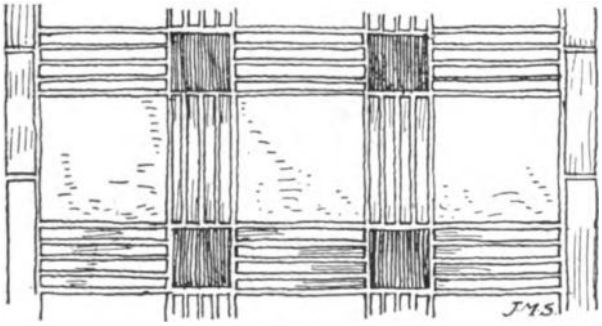
or Vitis inconstans, as it is at times called. As is well known, this plant clings by means of tendrils which secure a very firm hold on the wall. Another ampelopsis is called A. Lowii, which has very distinct foliage. Other self-clinging vines connected with the ampelopsis section include Vitis semicordata from the Himalayas, with foliage that is divided into three parts and is well coloured in the autumn, and V. Henryana, which is remarkable for its reddish silvery marbled leaves. The North American Vitis cordifolia is a very handsome plant, but this climbs by twisting its tendrils round branches, etc.

A climbing hydrangea from Japan is known as H. petiolaris, and this mounts upwards by means of aerial roots like ivy. The species should be used more extensively on walls, as it has an extremely neat habit of growth. In a sunny position it will flower freely during the summer. Every year, after flowering, the plant should be well pruned back. Two other related plants are Schizophragma hydrangeoides and S. petiolaris. Both these flower freely and attach themselves to walls by means of aerial roots. An evergreen plant known as Ercilla volubilis or Bridgesia spicata is sometimes offered as a self-clinging climber, but experience shows that the species is somewhat unreliable. Now and again it will cling well by means of aerial roots, but on other occasions it fails in this direction and needs support.—S. LEONARD BASTIN.

NOVELTIES IN GARDEN PATHS

AT this time of the year more than at any other gardeners realise any deficiencies that there may be in their garden paths. The rains of late autumn may have turned a grass path into a miniature morass, and the turf has suffered in consequence; while ordinary earth paths may be a sticky mass of mud. Therefore, some suggestions may be timely of a few novelties in garden paths.

It is as well, however, to remember that working paths, those which are in constant use and along which barrows are often trundled, should be entirely practical and made, if possible, of gravel, ashes or brick, or even, in very wet gardens, of concrete or asphalt. A fancy paving, however well it may be laid, cannot be expected to stand up against constant hard wear. It is amazing how often paving stones will be cracked or broken under the weight of a heavy barrow unless they are laid on a concrete foundation. The reason is obvious: if they are laid on earth, in time the foundation may be weakened or washed away under one corner, with the result that pressure on that particular corner of stone means an undue stress and consequent breakage. Utility paths are particularly necessary throughout the main vegetable garden, where most heavy work takes place.



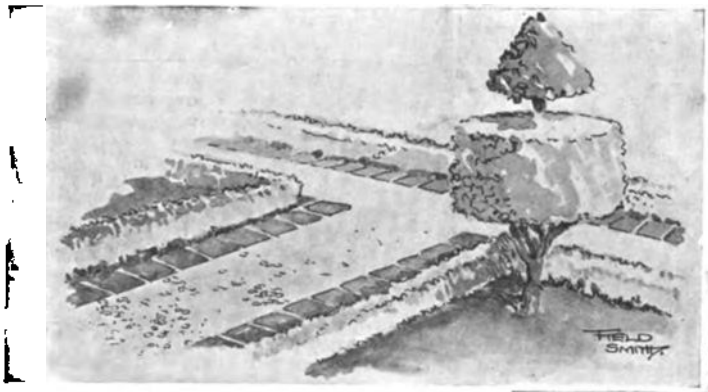
A PATH FORMED OF BRICKS AND TILES.

Made with 9ins. square tiles bordered by tiles on edge, 4ins. dark tiles at the junctions, and bricks on edge at the sides.

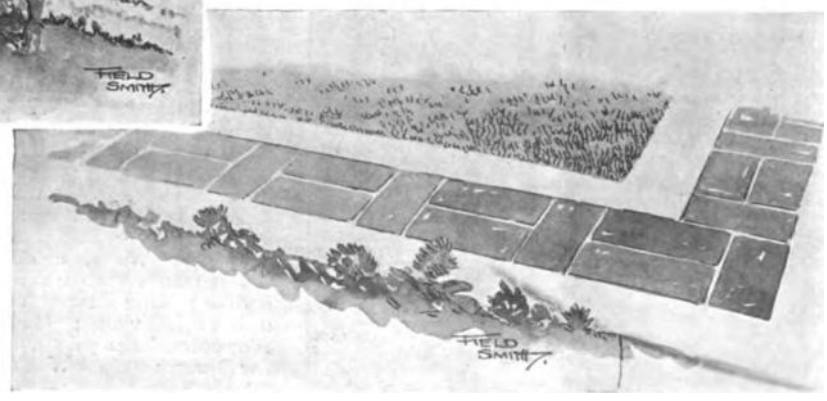
A STONE PATH BORDERED WITH GRASS.

It is in the flower garden that various designs in garden paths are so effective. The best path is undoubtedly that made of flags or old paving stones, but stone nowadays is so expensive that most gardeners find its extensive use out of the question. However, where a small quantity can be afforded, a most attractive path can be made either by using stone as a border for grass, or the converse—grass as an edging for a central stone path. In this way the quantity of stone required is not large; also, small pieces are suitable, which lessens the cost considerably. The only warning that should be given is to see, in both cases, that the grass is wide enough allow to a hand mower to be run over it, otherwise it will be difficult to keep neat and tidy. Although in the accompanying illustrations only stone is shown, yet an equally attractive path may be made out of grass edged with brick. For some reason or another bricks are not much used for garden paths, and this reason is difficult to find, for their mellow colouring combines well with grass, and, in addition, there are few neighbourhoods where bricks are not used extensively and where they are not made locally, which means a saving in carriage. They are easily laid without the help of skilled labour, and they are very permanent. They can be used in various designs; one of the most attractive is the herringbone, and this has an added attraction on the outside with its serrated edge.

An excellent brick and concrete path can be made where the inside is composed of bricks laid in parallel, each pair ended

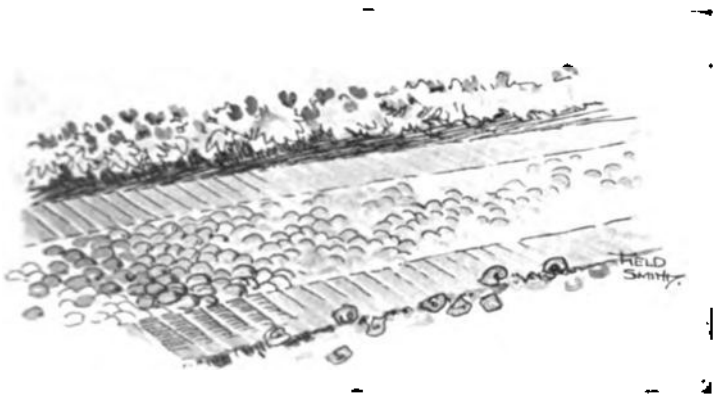


A GRAVEL PATH EDGED WITH BRICK AND BORDERED WITH BOX.

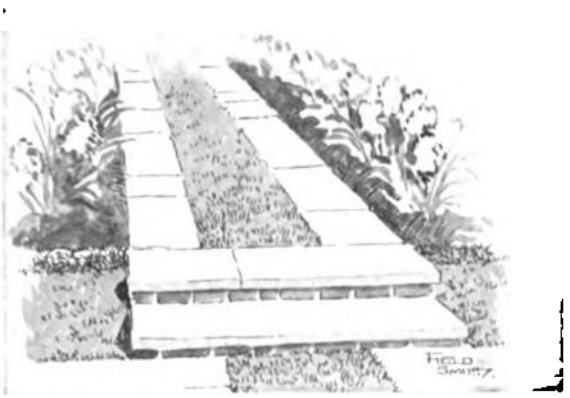


A PATH FORMED OF GREEN OR BLUE SLATES BEDDED IN CEMENT, WITH CONCRETE EDGING.

Digitized by Google



A COBBLE PATH EDGED WITH RED BRICK.



A TURF PATH WITH STONE BORDER.

with a brick laid across, while the outside edge is made of concrete. Here is a path that an amateur can make at little cost, provided he can spare the time. Still another attractive combination may be made by lining an ordinary gravel path with single bricks which have an edging of box on the outside. Gravel paths are often dull in appearance, and by means of a little ingenuity, as in this case, a novel and becoming path can be made, particularly at the side of a herbaceous border. In areas where tiles or slates are produced locally, and so carriage is cheap, there is no reason why they should not be used to give a little originality to the garden path. Readers can use their own imagination, but two examples of their use are shown on the opposite page which may help them in their choice. In all cases should gardeners make sure that the foundation is firm. Only too frequently are paths seen, excellent in design and execution, but which have become ragged and uneven through the ground sinking. It is not sufficient to level the soil; it must be beaten down and made perfectly hard before the finishing material is laid. In soft land it is always better to make a good foundation of old rubble, ashes or clinker. R. H.

THE LITTLE BOG GARDEN

An Interesting Experiment that Some of Our Readers Might Like to Try.

ONE of the most interesting additions to any garden is a small area of bog land. Of course, hardly ever will there be anything in the way of a natural site, and it is necessary to make the position artificially.

Situation and Size.

The situation for the bog garden should be fully exposed, as most of the plants which will be grown in the situation are sun lovers. The size of the bog garden will depend upon circumstances, but if the available space is limited the patch need not be more than 5ft. or 6ft. across. Here a basin is opened up in the ground to the depth of about a foot. The soil should be well beaten down and then coated with a layer of cement 2ins. or 3ins. in thickness. At the sides of the basin bricks will be found useful, but these should be covered with cement in order to keep back the water. Make an opening about 4ins. from the top of the basin to carry off superfluous water. It is also a good plan to have another opening in the bottom at the lowest point, which in the ordinary way is closed with a cork. This is useful should it ever be necessary to clean out the bog garden and drain away the moisture.

How to Proceed.

The filling of the basin is a matter calling for some care. Five or six inches of stones or bricks are first laid in, and these are succeeded by good peat soil. The surface of the rock garden should be raised into uneven banks and hillocks with large pieces of stone embedded in it here and there. In this way drier and wetter spots suitable for plants of different requirements will be provided. One side of the bog garden, which might be called the back, could be raised with rock-work, the stones being embedded in peat. Here, owing to capillary action, there will be plenty of moisture to sustain ferns and many other peat-loving species.

In most natural bogs there is at least a small trickle of water passing through the mass. This effect can be secured by filling in to the basin a few gallons of water each day, particularly during dry summer weather. It is very important to make sure that the bog garden never dries up—a happening which, in the case of a small basin, without natural water supply, is a real possibility. The retention of moisture is very greatly helped if, in the early days, the surface of the boggy tract is planted with sphagnum moss. The presence of the moss makes it much more easy to establish many of the typical bog plants than would otherwise be the case.

A LITTLE BOG GARDEN.

Suitable Bog Plants.

Many native plants form most interesting subjects for the small bog garden, and in addition there are some extremely handsome exotics which can be made perfectly happy in the wet patch. In fact, the number of species available is so large that there is a real danger of overcrowding. Among native plants one might mention pinguicula, drosera, parnassia, menyanthes, Viola palustris, Primula farinosa and the lovely marsh orchises. At the side of even the smallest bog garden a position should certainly be found for the osmunda fern, which will grow better in such a situation than anywhere else in the garden. Apart from British species attention may be directed to the interesting sarracenias, which, when once established, will develop their curious pitchers on an extensive scale. Trillium is another subject well worth growing and even the tiniest bog garden should not be without a plant of the moccasin flower (Cypripedium spectabile). In addition to the regular bog plants, practically all the choice alpines will thrive well in the drier or more elevated positions.

One of the great charms of the bog garden is that everything grows with vigour, no matter how dry the summer may be. In fact, one of the chief things on which to keep an eye is to make sure that the stronger plants do not overgrow and eventually destroy the weaker.

THE POT MARIGOLD.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow in the garden.

THE FAVOURITE SWEET ROCKET.

Calendula (Pot Marigold). ONE of the old-time hardy annuals, which of recent years has commanded a deal of attention owing to the introduction of improved strains. Flowers, both single and double, are of a deep orange and yellow, freely borne, and are much in request for cutting. Planted in groups in a sunny border, they make a brave show and continue in bloom for months from June onwards. They grow about a foot in height, and need but the simplest culture in quite ordinary garden soil to gain success. Seed can be sown out of doors in April, in a bed, from whence they can be transplanted, when a couple of inches high, to their blooming quarters. They are most effective when grown in groups. It is sometimes overlooked by those who have cold greenhouses—or houses where little heat is given—that calendulas may be had in flower late in the year, by sowing a couple of seeds in a 6in. pot of light soil at the end of August, retaining the strongest plant, and bringing them under cover a month or six weeks later.

Thalictrum (Meadow Rue). THESE hardy herbaceous perennials are very popular. Some are prized on account of their blossoms, and all because of the charm of their maidenhair fern-like foliage, which is of service for cutting, lasting in good condition for some time. A sunny or partially shaded position in the garden suits thalictrums, and any ordinary soil to which has been added leaves or vegetable refuse, to provide humus, will meet their requirements. A site should be selected where it will not be necessary to disturb them too frequently, and if it be half shady, as under a pergola, it will be found that, both in bloom and foliage, they will give the longest display. Their height varies from 9ins. to 5ft. In planting the clumps, which may be done in March, care should be taken to give each plenty of room for development, 3ft. between the strongest growers being none too much. Propagation is by seeds, which can be sown in April in pans of light soil in the greenhouse or frame, or by division of roots in October or April.

THE FEATHERY THALICTRUMS ARE ALWAYS POPULAR.

Hesperis matronalis (Sweet Rocket). IT would scarcely be accurate to include the double rocket, with its fragrant spikes of white and purple flowers, in a list of popular plants without qualification; but the fact is that, though once in high favour, particularly in Scotland, it is not grown as much as it deserves to be. Its neglect may be attributed to it being a somewhat peculiar plant, as, though hardy, it depends for its perpetuation on being taken up every second year and replanted in a fresh place. If this is not done, canker invariably sets in and it dwindles away. Even with this proviso, it is unwise to rely upon it mainly, but to propagate fresh plants from cuttings secured from healthy plants in early autumn, wintering them in a cold frame, either in pots or dibbled in a bed of sandy soil. The perennial forms grow about 2ft. in height, bloom from mid-May to July, and make good plants for the middle row of a hardy plant border. They are highly fragrant at night. When planted out they should be given a rich soil, in which old manure and sand have been incorporated. They love a sunny place, but like moisture at the roots in the form of humus.

Polygonatum (Solomon's Seal). ONE of the best of our hardy perennials for a shady position in the garden on the margin of shrubberies, doing well in town or suburban garden so long as it is planted in soil which contains a fair amount of humus. The flowers—seal-like appendages borne in clusters under their arching leaves—are singularly pretty. The plants grow from 2ft. to 3ft. in height, and if planted out singly should be given ample space. The best method of propagating Solomon's Seal is by dividing the roots in late autumn or March.

THE BUSY MAN'S PAGE

Cropping the South Border.

IN every garden there should be an early border where vegetables and salads may be sheltered and their growth advanced. To get the best effects this border should have a southern aspect, and it is a great advantage if it can have a sheltering background such as a wall, hedge or belt of shrubs. If nothing of this kind is available it is worth while fixing up a rough fence with hurdles, or forming one of laths between which straw is packed. Early produce is so valuable that it is worth while making an effort to get it, and if the south border is well sheltered, the first sowings can safely be made in January. Except in the case of extremely light soil, special attention should be paid to the drainage of the early border. In the case of a heavy clay it is an advantage to take it out to the depth of 18ins. and place in a layer of brick rubble and stones. When once the bottom is made dry the condition of the soil above can be gradually improved as opportunity offers. The surface of the border should have a good slope to the south to catch every ray of sunshine. Burnt earth, the sweepings from potting sheds, and any odd lots of compost should all be worked into the early border until a fair rooting depth is secured. The aim should be to get a depth of from 2ft. 6ins. to 3ft. and then it will be possible to grow anything.

On this border early vegetables of all kinds (peas, broad beans, turnips, carrots and even potatoes can be grown), but where the amount of space is not large, it is best to concentrate on salad plants, such as radishes, onions, lettuce, mustard and cress, etc. Should sharp frosts come along the early border must be protected. Fern, straw or any dry litter may be used, but sheets of newspaper answer every purpose. Spread the paper lightly over the plants and keep in place with stones at the corners. Have fresh paper every night so as to keep everything as dry as possible.

One great advantage of the early border is that it is practically in use all the year. Later in the season it will provide an ideal position for tomatoes, marrows, cucumbers and New Zealand spinach. Then, in the fall, the culture of salad plants will start again. One point should be borne in mind, and that is that the free drainage makes the border dry up very quickly. In the summer, copious waterings will be required if the crops are to be kept in a state of active growth.

January Reminders.

IN the flower garden and shrubbery any tender subjects should be protected with moss and fern. When the weather is open deciduous trees and shrubs may be planted. Manure and dig beds and borders. Any bulbs that are still out of the ground should be planted, except ranunculi, which are best kept over until next month.

In the fruit garden the planting of young trees may be continued. Wall trees should be pruned and trained. The growth of all fruit trees should be regulated, the branches, where badly placed, being thinned out. Mossy trunks should be dressed with quicklime. New plantations may be made for currants, gooseberries and raspberries. Old beds of strawberries should be mulched with manure.

In the vegetable garden protect broccoli and celery in frosty weather. Rectify all defects in drainage and trench, dig, and manure vacant plots. Early peas may be sown in a cold frame for transplanting into the open later on. This method yields better results than are secured by sowing out of doors at this early season. On a very sheltered border radishes may be sown. If a hot bed is available, mustard and cress, onions for salad, lettuce and carrots may be sown.

Plants for the Shady Wall.

ON the shady side of a rock wall it is important to select the plants with care as many subjects would not do at all in such a position. In the joints and courses of the wall flowering plants like willow gentian, ramondia, haberlea, Erodium Reicheri, Saxifraga longifolia, and most of the mossy kinds, Asperula hirta, Hutchinsia alpina, Campanula pumila, Omphalodes verna, Tiarella cordifolia and Viola gracilis would succeed. Such ferns as Asplenium trichomanes, A. nigrum, polypodium, ceterach and most

ASPLENIUM TRICHOMANES IS AN EXCELLENT FERN FOR CRANNIES IN A SHADY WALL.

kinds of polystichum would do well. If the wall presents a surface which is continually damp, one might insert Primulas viscosa alba, Cockburniana, latifolia, Bulleyana, Beesiana, and farinosa. At the foot of a shaded wall plants which would do well include trilliums, Lenten roses and Primulas rosea, japonica, pulverulenta and sikkimensis. The dodecatheons are useful subjects for such a position and, of course, many kinds of ferns might be employed with good effect.

Among the Shrubs.

THIS is the time of the year when fungus growths of many kinds are likely to appear on shrubs and trees. These growths, if not checked, are likely to do a great deal of damage and may even kill the specimen in the end. The attack always starts on some damaged or dead branch, from whence it may rapidly spread to the healthy tissues. Several times during the winter one should go through a shrubbery and examine trees, removing any dead wood. Branches and twigs that have fallen from trees should never be allowed to lie about on the ground, as these are sure to be the starting point for fungoid activities. Any abrasions on the bark should be treated with Stockholm tar, which will destroy any fungus spores that may have settled. After a strong wind or a snowfall, boughs may have been broken and, here again, exposed surfaces should be at once protected with tar.

Bracken in a Shrubbery.

THERE is no doubt that the bracken fern is an attractive addition to almost any shrubbery. Quite often attempts to establish the bracken in the garden are unsuccessful, and even if a few fronds come up at first, the plant disappears altogether the second season. Failure is largely due to the way in which the removal of the specimens from their original positions is carried out. The underground stems from which the plants arise should never be torn up from the soil as they hardly ever settle down happily in a new situation. The only way is to lift a good chunk of the soil in which it is known that the stems are present. Of course, the brown fronds of last year's growth indicate where the stems are likely to be. Mark out a rough square on the surface and then dig away round the outside of this to a depth of 8in. or 9in. Cut away the under part with an old knife and remove the whole lump. This should be settled in the new position so that the top part is level with, and is not covered by, the surrounding soil. A number of plantings of bracken may be made in this way, allowing about 6ft. between each clump. In the late spring the new fronds will come up and these will be of good size and generally not inferior to those borne by plants which have not been moved. When the bracken has become established it should be watched as it may spread to parts of the garden where it is not wanted. Fortunately, bracken may soon be cleared from land by the steady cutting down of the fronds when these are at the height of their summer growth. This practice so weakens the underground stems that they soon die.

Poultry Manure for Vegetables.

MOST gardeners realise that poultry manure is a valuable fertiliser, but they do not always use the material to the best advantage. On poor soil the poultry manure is an excellent stimulant for almost all kinds of vegetables and is especially useful in the case of celery, leeks and onions. As a rule it is better not to dig the material into the soil, for the best results are secured when it is employed as a top-dressing. It is well to make a practice of gathering the droppings from the shed at least once a week, and these should be placed on a large metal tray. The drying process may be hastened by placing the tray in any position where there is heat, such as on the top of a boiler. The manure is stored away in bags and it may be finally pounded with a hammer and passed through a sieve so that a fine powder is secured. In this way a good stock of the poultry manure is accumulated and it will prove of great service during the summer growing season. In use the manure is mixed with twice its bulk of sifted wood ashes or fine soil, and about once a fortnight this is sprinkled between the rows of plants. Use enough just to cover the soil with a fine coating, a large tin with a perforated top being employed as a sprinkler.

THE FLOWER GARDEN

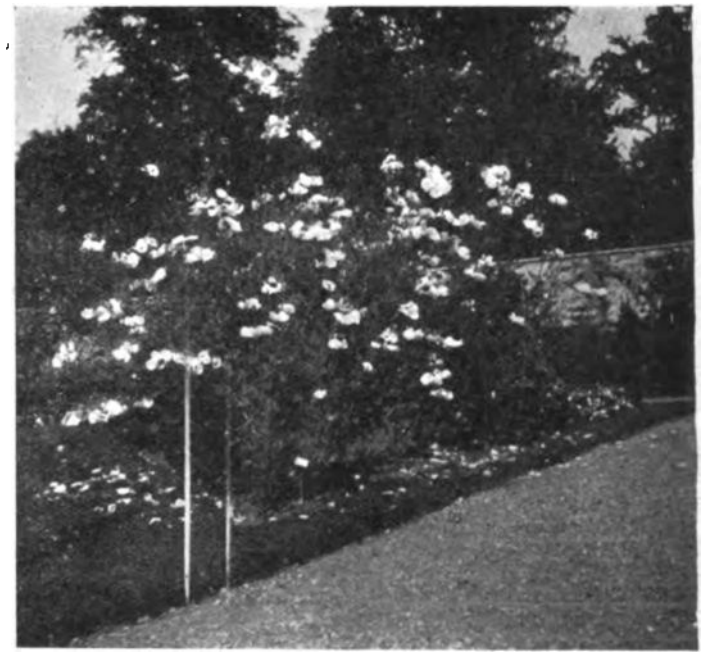
Cosmeas.

COSMEAS fell from favour for a time simply because they had too short a period of flowering; but matters have improved considerably of late, and they are sure to increase in popularity. They are among the very finest flowers for vase decoration, their slender stems, elegant and attractive "light" flowers and feathery foliage are a delight in the hands of those who can set them out daintily. Growers, when purchasing seed, should prefer the early-flowering hybrids; of these the singles are generally favoured, but the doubles are also very fine. The doubles are not fixed in any strain I have had, and, consequently, those who cannot grow as many as they would like may get plenty of singles from a strain of doubles. I should estimate that almost 75 per cent. come true to the double nature. Even with early varieties, early sowing is essential where the utmost has to be made of this flower. We advocate sowing in February in the usual way; from the seedlings select a number which are to be potted up in small pots. The latter, allowed to get pot-bound in April and May, flower as soon as they are put in the open, early in June. From the bulk of the plants, grown on in boxes, flowers can be had by the end of that month. Flowers will then be plentiful throughout the whole summer and the plants will remain in bearing right up till the first spell of frost. I do not urge too rich a soil for the cosmeas; they are at their best in a medium loam inclined to be dry, and, as everyone knows, they love the sun. An uncommon form is the Miniature Yellow, which bears small, star-like flowers in great plenty. Express, Pink Beauty and Lady Lennox are notable varieties of early-flowering nature. —CLYDESDALE.

COSMEAS ARE AMONG THE BEST ANNUALS FOR INDOOR DECORATION.

The Californian Tree Poppy.

THE Californian tree poppy has been described as a herbaceous perennial of the first water, and such praise is none too high for this noble member of the floral kingdom. Its succulent herbaceous stems attain a height of 4ft. to 6ft., and the leaves have a pleasing glaucous hue. The fine showy flowers are 4ins. to 6ins. in diameter, pure white, with crinkled petals and a central mass of golden yellow stamens. They are freely produced near the top of the shoots, and a well flowered example is a glorious sight. This tree poppy is much hardier than many imagine and it ought to be freely planted, except in the coldest parts of Britain. The best place for R. Coulteri is where it can get plenty of sunlight and away from overhanging trees and shrubs. Many corners on the south or west side of the dwelling house could be filled with a plant which would prove a thing of beauty from July to October.



THE CALIFORNIAN TREE POPPY, OR ROMNEYA COULTERI.

A deep, rich, sandy loam is an ideal rooting medium, but it will thrive in almost any garden soil providing it is well drained. This plant is an ideal subject for amateurs, and for those living in cold districts the near ally R. trichocalyx should be chosen, because this is the hardier of the twain, although from a floral point of view there is little or no difference. On one occasion I raised a batch of romneyas from seeds which were sown directly they were ripe, but the usual method of propagation is by root cuttings, which can be obtained at this period of the year.

It is not necessary to dig up a plant for this purpose, especially when only a few cuttings are required. With the aid of a spade or trowel it will be an easy matter to find a few thick, fleshy roots around the plant which can safely be removed without any undue disturbance of the specimen selected. These roots are cut up into pieces from 2ins. to 6ins. in length and then placed in pots or boxes filled with loamy soil. Cover the roots to the depth of half an inch and set the receptacle in a cold frame or shed till growth begins, when they are placed singly in pots or transferred to their final quarters. These tree poppies transplant badly, so young plants should be kept in pots till their final stations are ready. Purchased plants should also be pot grown.—T. W. B.

Geum Mrs. Bradshaw.

THIS is an indispensable plant and it is such a fine border subject that a large patch will be highly appreciated, while a bed filled with it would be a great attraction from May till July or even later. It is extremely popular, and when in bloom will be from 18ins. to 2ft. in height. The semi-double flowers are a brilliant crimson-scarlet and produced on stout branching stems, which render them ideal for vases and house decoration. Even when not in bloom the strawberry like foliage is always pleasing to the eye. This plant and others of its type will thrive in any garden where the soil is moderately good. A fine companion to G. Mrs. Bradshaw is G. Lady Stratheden; it is a glorified counterpart of the former bearing large clear yellow semi-double flowers, a strikingly handsome plant that is sure to give every satisfaction. It is extremely free-flowering, slightly more robust than Mrs. Bradshaw, and grows about 2ft. in height. A more recent addition is Orangeman, a characteristic feature of this acquisition being the flowering season, which is spread over a longer period than the two varieties already quoted. The flowers are semi-double and clear orange in colour. It is similar in growth and habit to the better known Mrs. Bradshaw, but a little taller.

The trio dealt with in this note are first rate border plants, they are quite distinct in colour from each other, and ought to be represented by several plants. Seeds are occasionally offered and this is a good method

Digitized by Google

by which the stock can be increased. I have raised a batch of G. Lady Stratheden in this way, and there was little variation in the colour of the flowers or habit of the plants.—T. BANCOS.

Nigella Miss Jekyll (Love-in-a-Mist).

THESE delightful annuals have always found favour among garden lovers, and especially those who often are forced to sow the seeds where the plants are intended to bloom. The nigellas are admirably suited for this purpose, but to secure the best results the seedlings must be thinned early to 6ins. apart. The thinnings can be transplanted to other beds or borders if the weather is showery.

The charming nigella illustrated is known as Miss Jekyll, and its easy culture, together with its free-flowering qualities, place it among the first dozen of our hardy annuals. The plant varies in height from 15ins. to 20ins., and the clear cornflower blue blossoms are produced on stout long stems, an attribute which makes them useful for cutting purposes.

The flowers are more or less surrounded with graceful, elegant foliage, and as a whole, particularly in beds or large patches they are most attractive.

In addition to the type, there is a dark blue variety of N. Miss Jekyll, well worthy of a place in the garden; while another counterpart of this annual has white flowers.

Although spring sowing is generally advocated, I would strongly advise readers to try an autumn sowing and note the difference between the plants. The latter will invariably produce by far the best specimens.—T. W. B.

Saxifraga aizoides.

OUR native Saxifraga aizoides must not be confounded with the silver saxifrage, S. Aizoon. It is of totally different character, and has, moreover, cultural needs of a distinct kind from those of the saxifrages of the Euaizoon section of this great genus. It is a moisture-loving plant, frequently found by the margins of runnels and streamlets on some of our mountain ranges. It has neat leaves and heads of small yellow flowers, insignificant individually, but, when the plants flower freely, quite pleasing in the mass. It is in reality a good little plant, only 3ins. or 4ins. high at the most. Pretty as it is, it is surpassed in attraction by the deep orange-coloured variety named S. aizoides aurantiaca, which is of quite a striking shade of reddish orange. It is an excellent plant and, as it frequently flowers late, it is welcome when in bloom. S. aizoides and its variety are easy to grow in a moist, sunny place, but where the soil is dry and as little attention as possible has to be given to watering, it may be planted in slight shade, and a soaking with clear water occasionally in dry weather will be much appreciated and will give better results. These aizoides saxifrages may be increased by division. They are perfectly hardy and may be planted in spring near the base of rockwork so that they may obtain any surface moisture flowing from above.—S. ARNOTT.

The Fumitories.

THESE useful little plants hardly receive the attention which they merit. They are not showy, it is true, and they have little variety of colour; but their fern-like glaucous foliage and neat habit of growth render them attractive, and with one or two exceptions they are quite hardy and will adapt themselves to almost any conditions, although they are happiest in a light soil. The best known among them is Corydalis lutea, which has become naturalised in some parts of England and is often regarded as a native plant. This will produce its bright yellow flowers in sunshine or shade from May onwards to the end of the summer; it is an admirable wall plant, and seeds itself so freely that it is apt to become something of a weed unless dealt with firmly. Much more uncommon, and earlier flowering than C. lutea are C. angustifolia (ivory white) and C. Alleni (cream flushed pink), the latter having specially pretty foliage. The tuberous rooted C. bulbosa, the colour of which is a rather dingy pinky purple, usually follows these in order of flowering, but in some seasons it leads the way, a note in my garden diary recording the fact that one year it was in bloom on March 29th; it is good for naturalising under deciduous trees. Corydalis cava, also early, is a brighter shade of purple than bulbosa, with which it is sometimes confused. Both these, as well as the white variety of cava, albiflora, have but a short flowering season and die right down in early summer; hence they often come to an untimely end by being forked up. None of the fumitories named exceeds 8ins. or 9ins. in height, but there is a still dwarfer one, C. ochroleuca, which is a charming little plant for the rock garden. Among the taller kinds—that is to say, those growing from 12ins. to 14ins. high—the best are C. cheiranthifolius (clear bright yellow), which seeds itself nearly as lavishly as C. lutea; C. Ledebouriana (pinkish mauve); and C. thalictrifolia (yellow). C. Ledebouriana is one of the hardiest of all, but C. thalictrifolia requires a little winter protection in the colder parts of the country; it is a pretty border plant (although it does best on a limestone ledge), its flowering season is long and its foliage turns a rich red in autumn. There are two fumitories that reach a stature of 2ft. or thereabouts which are seldom seen but are well worth growing, to wit, C. capnoides and C. nobilis. Both are yellow; the first blooms in spring, the second, which is the handsomer of the two, in summer. The latter does not increase quickly and its seed is slow germinating.—R. E. HEAD.

LOVE-IN-A-MIST MISS JEKYLL IS VERY FREE FLOWERING.

ONE OF THE TALLER-GROWING FUMITORIES, CORYDALIS NOBILIS.

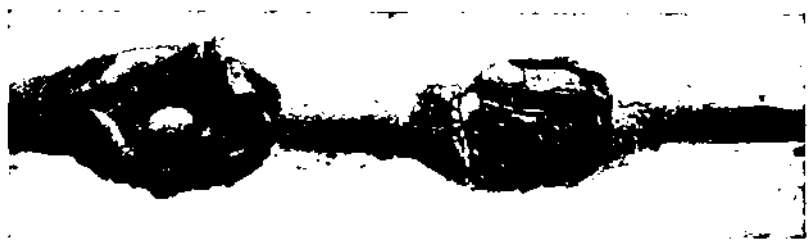
THE FRUIT AND KITCHEN GARDEN

Canker in Fruit Trees.

THE incidence of the amateur in fruit-growing and the large amount of Continental stock sold, have undoubtedly led to a wide spreading of canker disease. The disease is not always recognised, unfortunately, but as this is the time of year when it can most readily be "spotted," I would advise all readers to take a second look at their trees. Canker affects only the trunk and the branches, generally the lower part of the branches and, very often, quite close to the fork. At first it is merely a small patch of scab or rugged corky bark; later a wound appears with rough corky edges; this next increases in size and becomes ugly, but still retains the corky rugged edges; the last phase is when it encircles the branch and kills it. Fruiting bodies of the fungus or germ may be noticed as minute white specks in autumn or as minute red balls in spring; these are not readily visible to the unaided eye. An infested branch shows gradual diminution of fruiting power and vigour. Germs of this parasitic fungus can only infect a tree through a wound; wounds, however, may be due to insect attack, to the effect of storm, to the strain of heavy fruiting, to a casual knock, to tight ties, or friction against a post or wire. Some of these, such as bad insect attacks, tight ties, etc., may be prevented, and the first step towards immunity is, naturally, prevention. When an attack does materialise it may be prevented from doing damage by the early use of the knife; the infected part is cut clean away, much of the bark above and below the wound is removed and all discoloured wood in addition. The large wound, of necessity left open by this, is then covered with a cream of lime, clay and water, or, better still, it is coated with tar or paint, preferably the former. Badly infested branches ought to be sawn off, well back, too, and burned. As the spores of the disease may pass to open wounds from infested tissue lying on the ground, it is most important that diseased shoots are burnt at once. As these spores float round in the air, or since they may be carried about by other agencies, it is not wise to remove canker at pruning time; et it be done some time before or after, when the pruning wounds are partly healed up. It is most important to note that while apple, pear, plum and nut trees are often infested in gardens, yet the disease is found on beech, elm, lime, etc. Trees in or adjacent to the garden may, therefore, be treated with advantage at the same time. Fruits which send their roots down into a harsh, cold subsoil, are first to suffer, so we, in Scotland, often put slates or flagstones below a new tree. Some apples, too, are more susceptible than others, the more refined the variety the greater the chance of attack. The moral of this article is watchfulness on the part of the grower, particularly with new trees received from the nursery.—CLYDESDALE.

APPLE CANKER IN ITS EARLY STAGES.
The oval diseased portion can clearly be seen.



AN OPEN WOUND SURROUNDED BY SWOLLEN BARK, TYPICAL OF CANKER.

Leeks.

BEFORE the stock of leeks grown last year is exhausted, we are busy preparing for the current year's crop. Undoubtedly, large leeks are economical and better from a culinary point of view than small ones. It is not possible to grow large leeks from seeds sown in the open border in April. If they are fairly large they are not solid, owing to the undue forcing of the growth through the aid of stimulating foods. The big leeks are grown from seeds sown under glass, either in deep boxes or beds in frames. In any case the soil used should be passed through a ½in. mesh sieve, so that when the resultant seedlings are lifted for transplanting in their permanent quarters, or in other boxes, all soil will fall away from the roots, leaving the latter intact, a very important point. It is rarely possible to transplant the seedlings with soil attached to the roots. The depth of soil should not be less than 9ins., for, although the young plants are smaller and more weakly than young onions, their roots penetrate as deeply, often deeper. When leeks are planted in their summer quarters the roots should be placed in deep holes made by a hand trowel, not with a dibber. If there is a desire on the part of the cultivator to transplant before the final planting, transfer the young plants to boxes of soil or a bed in a frame. Do not pot them singly. I have tried this plan more than once and found it did not answer as well as planting in boxes. The trenches should be prepared now; I make them nearly 3ft. deep, put in a liberal quantity of rotted manure and soil, mixed; a small quantity of dry fowl manure and some bone-meal. When short of farmyard manure, I have used hop manure with splendid results. The trench is filled almost to the top, as I like to provide a good, deep layer of rich soil for the roots to permeate. By planting out time—the end of April—the soil has settled down firmly.—G. G.

Fruit Tree Suckers and How to Deal With Them.

PERHAPS the greatest trouble comes from plum, peach, nectarine and apricot trees as regards the growth of unwelcome suckers. As there are thousands of young trees being planted at this season, it will be helpful to inexperienced cultivators to give a few hints on treatment. I daresay that many readers have noticed slightly raised and roundish lumps on the roots of some young fruit trees when they are lifted for replanting or just received from the nursery. Very frequently suckers will grow from these lumps on the roots in later years and then it will be more difficult to deal with them. Carefully examine all roots and, with the aid of a sharp knife, cut off the lumps or slight swellings found, making that part of the root as even in size as the other, smooth part. If this is done a number of small fibrous roots will grow from the cut part and they will be of great benefit to the tree in after years. The stocks of plums give, I think, more trouble in this way than any others, and, where suckers are already growing through the soil, do not cut them off and be content. If cut so, they will rapidly increase and soon become a bunch, where previously there was only one. Carefully take away the soil and lay bare the roots from which the suckers are growing, then as carefully cut out the suckers at the base, removing a portion of the root also. It will be found that the lumps or swellings are formed as in the case of very young trees, only they will be larger and every bit of such swelled root should be cut out. When this work has been done, in the case of stone fruits, place a small spadeful of old mortar rubble round and over the cut parts. Fibrous roots will grow and the tree will improve in growth and fruit bearing.—CHRISTCHURCH.

Why Pears Fail.

PEARS are a precarious crop in many parts of the country, in others they are somewhat irregular, and only in comparatively limited areas do trees regularly bear crops of satisfactory excellence. There may be many reasons for the failures, but these, on investigation, generally reduce themselves to one or more of three. Years of experience show that attention to these three "possibilities" is a fairly certain guarantee of cropping.

A very general reason for unfruitfulness lies in the root system of the tree. Pears tend to root fairly deeply and the roots ramble below the usual depth to which a garden is dug; they then penetrate into a barren, harsh and cold subsoil, where nourishment is scanty and the soil cold and sour. Very often this subsoil is of a clayey nature, where the evil conditions are accentuated. However, I have clearly proved that as soon as the root system gets well embedded in the subsoil the tree begins to lose its ability to carry fruit. In time the tree may

Digitized by Google

refuse to bear any fruits, though it appears to be healthy. In the north, here, the laying of flat stones, slates and the like under pears at planting time is generally advocated. Old trees not fruiting must be root-pruned and, after pruning, it is a wise plan to slip in similar floors under the roots. I have seen excessively hard pruning of some quite old trees, but invariably the result is a rapid return to fruitfulness.

Very much similar to the above is another cause, starvation. Professional gardeners always fed their trees well in the past, but the present-day amateurs are too prone to expect miracles without kindness on their part. Pears must be fed fairly well. Provided that there is a fair amount of humus in the ground, artificials will do quite well, but the pear trees must have food annually. I find that application of artificials in the beginning of April, again in the beginning of June and a third application to help the buds (for next season) in August amply repay the expense incurred. For older trees a top-dressing of rotted turf, applied after paring off some of the exhausted soil, is excellent. In light soils a mulch in summer is also extremely useful. Where manure is plentiful I should apply it every year, or at the outside every second year.

In many parts of the country pear blossom is often blighted by cold winds, cold rains, sleet and frost. Invariably I find it necessary to protect some of the trees, and this I always try to do with frame and other sashes. Mats are also very good, provided that there is some suitable way to suspend them in position. Each grower will know exactly where protection is always needed and be prepared, but in certain years every tree needs to be seen to. Readers who may be annoyed at their pears will possibly find the reason for their annoyance explained above and be prepared in future. This is the correct time to renew the surface soil and to root prune.—CLYDESDALE.

Pruning Bush Fruits.

IN many districts the autumn pruning of gooseberries is rarely attempted on account of the birds. If the bushes are pruned then and left unprotected, very few buds would be left on them by spring. Where the birds can be kept off, undoubtedly autumn pruning is best, as then the buds retained swell more and the resultant berries are available for use about one week earlier than on bushes of the same varieties pruned in spring. Some of our finest varieties are of a pendulous habit of growth, and the lower branches sometimes require staking. A little extra care should be taken in the work of pruning the bushes so that all shortened shoots are cut to a bud pointing upward. If, year after year, this is the practice, the bushes are kept uniform and of a better shape. Where the big bud in black currants is troublesome, all pruned shoots must be burned and the remaining buds closely examined, so that all abnormal buds are removed. It is not of any avail to cut down bushes close to the ground with a view to eradicating big-bud. I have seen this done and the resultant failures. The year following, splendid shoots grow, but the second year the mite is at work again. Red and white currants should be so pruned that spurs, covered with flower buds, are numerous on the main branches. It is advisable to thin out freely branches near the centre of the bush, as finer fruits of richer colour result than on bushes of dense growth in summer.—G. G.

Early Peas.

THE most satisfactory method of raising early peas is to sow the seed in boxes placed in cold frames, and transplanting outside when the weather is favourable in early spring. Sowings may also be carried out under glass, and again at the end of the month on a warm south border in the open. The boxes in which early peas are sown should be properly drained and the compost should be light and well watered after sowing. On all possible occasions the lights should be kept off the frames, and only be used to protect the young peas from severe frosts. The seed should be sown fairly thickly for outside crops, in order to allow for a certain number of seedlings being destroyed by birds and pests. Dwarf varieties are the most satisfactory for early supplies, two of the best being Little Marvel and Carter's Giant Stride. The latter is the largest podded dwarf pea; it bears remarkably heavy crops, and is of excellent flavour. Little Marvel has small pods, but it is very prolific. American Wonder is a favourite dwarf pea; Excelsior is also good; and Carter's Daffodil, a good cropping variety with large deep green pods, can be well recommended.

WHAT OUR READERS SAY

A WELL-FLOWERED HYACINTH.

SIR,—The accompanying illustration may be of interest to readers of THE GARDEN who are interested in bulb culture at home. It is a hyacinth which gave eight blooms from the one bulb, grown in water by Miss Freeman at the Military Road Council School last season. In colour it was rose pink and is of unknown name.—HENRY E. COOPER, *Northampton*.

A HYACINTH WITH EIGHT BLOOMS.

THE ONOSMAS.

SIR,—The onosmas most generally cultivated are O. echioides, perhaps better known as O. tauricum, and O. albo-rosea, and both are very beautiful plants, full of interest and worthy of a position in all rock gardens, large and small. Popularly known as the "Golden Drop," O. echioides produces heads of amber coloured blossoms, drop-shaped and delicately almond scented; the stems are much branched and clothed with lanceolate, greyish-green and rather hairy leaves. The plant grows about 12ins. or 18ins. high and flowers May-June.

O. albo-rosea forms a tuft of grey woolly leaves and from it rises, during the early summer, panicles of white, flushed very delicate pink, blossoms which contrast exquisitely with the hoary foliage.

These onosmas should be placed rather high in the rock garden and they are never more beautiful than when their blossoms are tumbling over the edge of a bold stone; they enjoy full sunshine and a well drained gritty soil. During excessive winter wet, the protection afforded by a piece of glass may be advisable. They will, however, be quite safe fully exposed in any ordinary weather. Propagation is easily effected by cuttings inserted in sandy soil in a cold frame during the summer months.—RALPH E. ARNOLD, *Campden, Glos.*

AMERICAN BLIGHT.

SIR,—In your issue of December 25th, 1926, your correspondent "R. C." recommends the use of petrol for the destruction of American blight upon apples. There is surely no occasion for "marking the starting point," as petrol is of very little use during the winter months, when the colonies of the pests are safely protected within the bark or warmly ensconced underground. Petrol is highly effective during the summer months when the woolly patches of blight make their appearance on the bark. I have followed your correspondent's method—a little petrol in a tin and a small paint-brush—and the woolly colony vanishes like smoke. Petrol is perfectly safe on old bark, but it is too scorching for new and sappy growths. American blight is frequently found infesting young wood, particularly round the axils of the leaves. An agent of equal or even greater power of destruction is methylated spirit applied in the same way, and it has the additional advantage of not "burning" the young growth. May I suggest to your readers who may be troubled with mealy bug on vines that they *experiment* with a spray of methylated spirit and water on infested foliage?—HERBERT G. LONGFORD, *Abingdon*.

RED CURRANTS.

SIR—The article on the red currant in the December 18th, 1926, issue of THE GARDEN contained much useful information, but on two points I am not in agreement with the writer.

Firstly, the growing of bushes with a leg is, in my experience, a mistake. Most gardeners have experienced the irritation which a currant bush with only half a head causes. Disease is often responsible for a whole branch dying back, and, with some kinds, wind, or even the weight of a crop, will cause a branch to snap close to the stem. It is generally impossible to get a new shoot to replace the loss, and, sooner or later, the lop-sided head splits off entirely, or the gardener removes the eyesore.

My method is to plant cuttings without taking out the lower buds, thus ensuring the growth of suckers every year. This gives an opportunity to replace a breakage, and also to renew the tree branch by branch as it ages or

Digitized by Google

loses vigour. The only disadvantage is the growth of suckers which are not required, but if these are removed when soft, about twice during the spring, it suffices. It is worth doing to ensure a permanent tree, with growth renewable at will.

My second point of disagreement is in the age of permanent planting. Much better results may be expected if permanent positions can be found for the maiden bushes than if they are lifted and replanted in nursery rows, to be again lifted the following year and put into permanent places. There is no particular merit in a two year old bush for planting, beyond its age, and having reached that age with only one disturbance, instead of two, is surely to its advantage.—E. BROWN, *Sittingbourne, Kent.*

SYNONYMS AMONG TULIP NAMES.

SIR,—There was undoubtedly a good deal of confusion over tulip names before the appearance of that excellent report, compiled with infinite labour and patience by the Tulip Nomenclature Committee on behalf of and published by the Royal Horticultural Society in 1917. This work was rendered necessary by the keen revival of interest in tulips and the consequent introduction of many varieties which had, as one might say, been rediscovered in gardens; these were in some cases recognised and correctly named and in other cases renamed, causing considerable confusion. Therefore, in 1913, the Council of the R.H.S. decided to appoint a Committee of English and Dutch experts to draw up a scheme of classification, which resulted in the report above referred to. Going through Mr. Longford's letter in THE GARDEN of December 18th with this work before me, I find that the cottage tulip *Bouton d'Or*, has synonyms Golden Beauty and Ida. The cottage tulip *Bronze Queen* has synonyms Clio, Biscuit, Sensation and Duc d'Orleans. The cottage tulips *Orange Beauty* and Prince of Orange are synonymous, but I think the latter name is the better known, since it was exhibited at the Chelsea Show in 1924 by me, inadvertently, I must confess, as Prince of Orange, and received an award of merit under that name There are also the Dutch florists tulip *Prince of Orange* broken and the double early *Prince of Orange*. The cottage tulip *Globe of Fire* has its synonym Gesneriana aurantiaca. *General Ney* is an inferior Orange Beauty. The cottage tulip *Boadicea*, a very fine and deliciously scented variety, is similar to but rather smaller than *Hammer Hales*. The Dutch florists tulip *Panorama* has its synonyms Monument and Fairy. The parrot tulip *Crimson Beauty* has its synonym Cramoise Brilliant. The single early *Cramoise Brilliant* has its synonyms Carmine Beauty and Sparkler. Early Darwin is not mentioned. The Darwin tulip *Bartigon* has its synonym Lord Duncan and the Darwin *Mrs. Potter Palmer* has synonyms Mr. W. D. Fish and Fashion. The Darwin *Nauticus* has its synonym Sir Edward Grey. There are Rembrandt tulip *Dream* and the Darwin *Dream*, with its synonym Reve de Jeunesse. There is the Dutch florists *Grand Maitre* and the same broken. There is Darwin *The Sultan*, purple black, with its synonym Joseph Israel. *Suzon* is quite distinct and is rose shaded cream. The Darwin *Faust* has its synonym Ravenswing. The Darwin *William Copland* has its synonym Sweet Lavender. There are the single early *Blushing Bride* and the Darwin *Blushing Bride*. The cottage *Isabella* has its synonyms Blushing Bride and Shandon Bells. The cottage *Picotee* has its synonyms Maiden's Blush, and there is the Darwin *Maiden's Blush*. The Cottage *La Vierge* is an inferior Picotee.

The names recognised by the Tulip Nomenclature Committee are in italics. These varieties are only the few that Mr. Longford has drawn attention to. The Report gives a list of several hundreds of synonymous varieties and should be in the possession of everyone interested in tulips.—W. A. WATTS.

AN ATTRACTIVE CANADIAN WILDING.

SIR,—One of the most delicate and winsome flowers of the woodland in Southern Canada and the Northern United States in the blood root (Sanguinaria canadensis). Almost before the snow has disappeared, the flower stalk, bearing a small bud closely enveloped in a pale green leaflet, pushes through the ground. The stalk grows rapidly until it attains a height of about 6ins., when the sheathing sepals fall off, exposing the pure white petals, eight in number, centred by golden tipped stamens. Nothing is prettier among the shade-loving plants of the spring garden in the rockery or nestling among shrubbery. Gardeners are familiar with the single form, but the double flower is not so well known. Many horticultural writers, including Robinson, describe the single flower only. The specimen here illustrated is growing in the garden of Mr. W. T. Macoun, Ottawa, Dominion Horticulturist, the parent plant being in the possession of Mrs. Klotz, whose husband, the late Dr. Klotz, for many years Dominion Astronomer, obtained the original plant from the neighbourhood of Ann Arbor, Michigan. — GEORGE SIMPSON, *Ottawa, Canada.*

THE DOUBLE FORM OF THE CANADIAN BLOOD ROOT.

HAS IT GONE OUT OF COMMERCE?

SIR,—The enclosed illustration of Chrysanthemum Honeysuckle may interest many of your readers. I have had several gardeners and chrysanthemum enthusiasts round to see my little collection, and all have admired this chrysanthemum. None of them had ever seen or heard of it before, and I was asked where I got it and where it could be obtained. I have looked over one or two catalogues, but cannot find it listed. It is a pity if such a charming flower has gone out of commerce. No doubt one of your readers will be able to give me some information through the coloumns of your valuable paper and, incidentally, help my enquirers should they be readers of THE GARDEN. I shall not make any attempt to describe the flower, only that it almost exactly resembles (except for the yellow eye) that well known and beautiful climber after which it is named. —E. C., *Cullompton, Devon.*

THE BEAUTIFUL CHRYSANTHEMUM HONEYSUCKLE.

PLANTS FOR THE BEGINNER'S ROCK GARDEN.

SIR,—Among the plants recommended by Dr. R. Lloyd Praeger for a beginner's small rock garden Potentilla nitida is named. I have seen it growing wild in the Dolomites and, when covered with flowers, it is extraordinarily beautiful. But for the last ten years I have had it in my garden and rarely has it produced flowers, and that also is the verdict of friends from whom I have enquired about it. Therefore, I shall be glad to hear what your correspondent has to say in its favour. It is true that its silvery leaves are attractive, but it is hardly to be supposed that the owner of a small rock garden wishes to fill up his limited space with plants which rarely produce flowers.

I am also interested to see that "T. W. B." mentions as a point in favour of Campanula persicifolia varieties that "they are not aggressive, and will not encroach on their neighbours." That is not my experience. I am obliged to treat the endless seedlings as weeds. I am on the carboniferous limestone, and that may account for their fertility.

The information given in THE GARDEN would be still more helpful if the locality and the nature of the soil were mentioned by each writer.—W. STORRS FOX, *Bakewell.*

MICE IN THE GARDEN.

SIR,—A simple and effective mouse trap can be made with two brickbats and a few inches of galvanised iron wire. With a pair of pliers bend the wire into the shape of an S, making in the centre a kink, which is not obligatory, but is useful, as it helps to keep the bait steady. Thread a piece of cheese rind or, better still, a bit of Brazil nut kernel on to the wire till it is checked at the kink. All that remains to be done is to set the trap. Lay one brick on its side close to and parallel with a wall, fence or hedgerow—or the seed drill—on a flat bit of soil. Lay the other brick parallel to it on its edge, preventing it from falling flat by means of the S-wire, which with a little adjustment just holds the bricks apart. The only precaution to observe is that the second brick when it falls should have sufficient space to do so without catching the side of the first one, thus allowing the mouse to escape.—C. J.

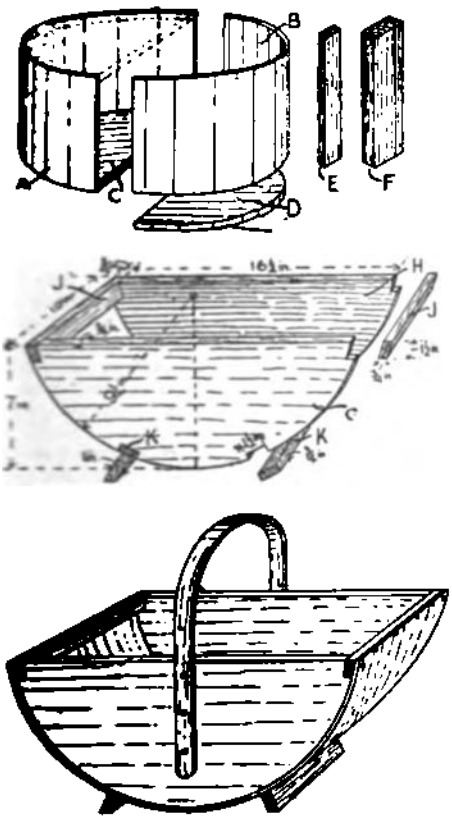
GARDEN ODDMENTS

Greenhouse and Garden Equipment.

WITH the advent of the New Year the thoughts of the gardener go out to the time when operations out of doors, such as the sowing of seeds, etc., may be commenced in earnest. As yet there is little one can do beyond finishing clearing any ground that still needs to be done and completing any digging when one can get on the soil. Undue haste in this direction, however, when the soil is not in a proper condition for working, is calculated to do more harm than good. But there are other matters to be attended to, and among them is the taking an inventory of one's stock in trade, so that when the time arrives for work one will be fully equipped.

For the Garden.

All tools should be thoroughly overhauled, and if it should happen that some of them show signs of rust, or were put away in



FIGS. 1, 2 AND 3.

not the best manner, opportunity ought to be taken to clean them thoroughly. This includes spades, forks, rakes, hoes and other hand-tools. The lawn mower put away last autumn should be examined, and re-oiled if need be. Pea-risers and bean sticks should be collected together.

For the Greenhouse.

Under glass it will soon be necessary to make plans for the sowing of seeds. With this in view pans and boxes should be looked up and any repairs that are wanted by the latter should be done. One of the most important articles used is compost, and this should be got together under cover. Loam, leaf-mould, sand, peat, are essential in most greenhouses. Manures and fertilisers needed must not be lost sight of. Soot, lime and wood-ashes, while only required in a moderate way for plants under glass, must be taken into account for use in the vegetable garden. Flower pots and sticks may need replenishing, and a stock of crocks ought to be kept handy for use when the potting on of rooted cuttings, etc., begins, and labels will not be forgotten by the one who desires to "know what is what."—W. F.

How to Catch Moles.

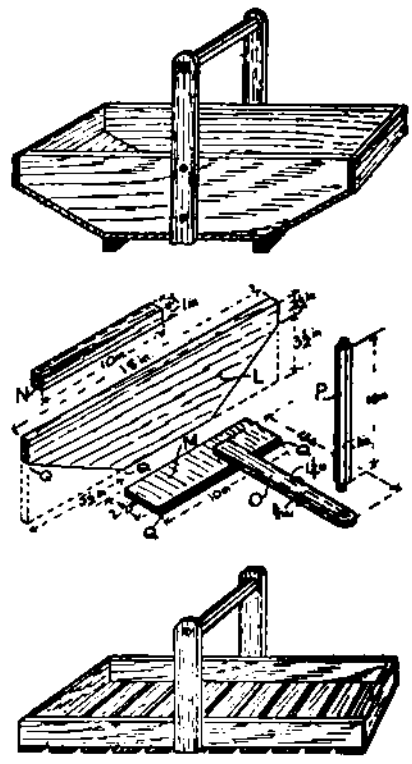
THERE is no royal road to success in mole-catching and the "secrets" which the mole-catcher is supposed to possess are humbug. Nor is the mole the peculiarly shy and cunning creature he is often proclaimed to be. The great essential is to find the right hole. It is practically useless setting a trap in one of those shallow, tortuous burrows which are the most aggravating evidence of Talpa's appearance in the garden. These are feeding runs and are seldom traversed twice. But, find the main avenue, the deep, firm-walled burrow, which the creature uses every time he goes to and from his feeding places, and, with no very exceptional skill, the mole should be trapped in a few hours. This burrow may come from a wall or hedge, it may pass under the garden path or take the line of least resistance around a boulder in the rock garden. Generally, there will be nothing to show above ground, but here and there one may see a little fresh soil pushed up. The trapper must depend on his trowel or a pointed piece of iron in discovering the track, and once it is found and proved to be the right one, it should always be marked for future use. I have used several such holes for nearly twenty years and they still catch whensoever there is a mole about.

Of the trap and its setting little need be said. I always use the ordinary iron pincher trap. The hole to take this, with nippers extended, is made across the run and the latter is cleared of any loose earth. The trap is then set so that the mole must pass between its nippers. A thin piece of turf, or sod, is placed over the hole and on each side of the trap, but not so as to hinder the free outward spring of the handles, and the thing is done. As I have said, I always scrape the hole clear with my hands, never trouble about handling the traps with gloved fingers and yet I am invariably successful. Should the trap be sprung by soil pushed ahead of the mole as he proceeds, clear the run, re-set the trap and the chances are that the following night will bring reward.—A. T. J.

Easily Made Garden Baskets or Trugs.

ALTHOUGH the name basket is generally given to articles made of wickerwork, the garden trug, made of wood, is often called a basket. The trug shown in Fig. 1 is a convenient shape for many garden purposes, and it is made quite easily from a cheese box. The method of construction is shown at Fig. 2, in which the lower portion of the cheese box has been cut in half, the two sections being marked A and B. One of the halves is used for making the body of the trug; this we will suppose is the section at A. As it is, there is only one side formed by the bottom of the box, as at C. To provide the other side, the bottom of the other half, as indicated at D, is fitted at the top of the section as shown by the dotted lines. To strengthen the top ends of the trug, two strips of wood, as at E, are screwed to the sides and outside pieces as shown at Fig. 1, and two pieces with bevelled edges, as at F, screwed to the bottom to keep the trug upright. The handle is formed from the band surrounding the rim. Another trug can be made by utilising the wood from the lid, this can be cut in half and the remaining section B screwed to the pieces.

A similar trug can be made from two sides of ¾in. board, as shown at Fig. 3. The sides G and H are joined together with strips of 1½in. by ¾in. wood, as at J and K, and the curved portion covered with thin plywood, a strip 10ins. wide and about 25ins. long being required. Thin plywood will bend to the curve, but the material should be screwed at intervals of 3ins. or so. Another form of garden trug is shown at Fig. 4, the various parts, with dimensions, are shown in Fig. 5. The two sides, L, should be cut from ¾in. machine-planed floorboard, a piece of ¾in. board or ¼in. plywood, M, being nailed to them; two feet, N, are then screwed underneath. The handle is composed of two strips, O, screwed to the sides with a length of round wood, broom handle will do, fitted between. The only difficult part of the construction is in the fitting of the mitred corners of the bottom pieces as at Q, but if a sharp plane is held at the correct angle, the edges of the wood are easily planed down. The best plan is to fit on the two end pieces, then the sloping pieces and leave the bottom piece to the last. The trug shown at Fig. 6 can be made to any convenient size, for the sides



FIGS. 4, 5 AND 6.

use 2in. by ¼in. wood and for the bottom strips, 1½in. by ¼in. wood will be stout enough. The handle can be made of strips similar to those used for the sides, with a length of broom handle fitted between. When finished, the wood should be sized and varnished or given a couple of coats of paint.

Keeping the Hands Clean.

MANY of the jobs to be done in the garden mean dirty hands unless one happens to be wearing gloves. Gloves are all right in their way, but there is no doubt that, to an extent, they hamper the movements of the fingers. To keep the hands, and particularly the finger-nails, clean it is really a very good plan to rub a cake of somewhat dry soap over the fingers before starting the work. When the hands are washed, at the conclusion of the job, it will be found that they are quite free from stains and the finger-nails are not filled with dirt. —S. B.

GREENHOUSE NOTES FOR JANUARY

Clematises as Indoor Climbers.

WE are frequently reminded of the beauty of clematises for gracing walls, pergolas and arches in the garden, and hear too little of their attractiveness for cool houses. It has to be said, nevertheless, that given right conditions some of the members of this showy family are never happier than when their blossoms festoon from a roof or glass porch, with enough air and shelter to admit of their flowers opening in fullest splendour. Sometimes one notices that greenhouses are erected against walls or the end of a house, and escape most of the heat of the sun; in fact, some of them only get the sun for a portion of the day. It is these houses in particular where one may look for and attain success with this, one of the chief of our flowering creepers.

Varieties.—The one clematis, which is the least hardy, and therefore best accommodated when grown indoors, is C. indivisa lobata, producing its white star-like blossoms in greatest profusion. Among the Jackmanni and lanuginosa types, there are some excellent sorts that, grown on the rafters of a house or trained on a trellis on a back wall, are seen to good advantage. From the first named type a selection could be made of sorts like Alexandra (pale reddish violet), Prince of Wales (deep pucy purple), Mrs. Cholmondeley (blue), and Smith's Snow White. The large-flowering lanuginosa group contains many of exceptional merit, and the owner of a cold house can make a good selection from Beauty of Worcester (bluish-violet with white stamens), lanuginosa (pale lavender), and Nelly Moser (light mauve with red bars).

Planting.—Clematises, with the exception of indivisa lobata (which is best planted out in a bed inside the house), are more conveniently dealt with grown in large pots or tubs, as at times (as for example, after cutting down), they may be stood out of doors for a while, or placed in a cold frame.

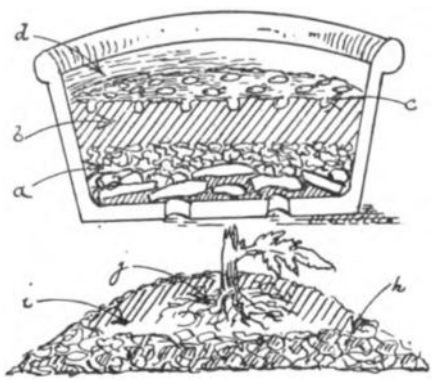
Culture.—In shifting them into their flowering pots, a compost should be made up of good rotted loam or leaf soil, in the proportion of two of the former to one of the latter, along with one part of decayed cow manure and a good sprinkling of sand. As clematises can always be procured in pots, it is an advantage to do what repotting is needful before much growth has been made, so that the roots may have a chance of being spread out in the new compost. Special attention should be given to provide sufficient drainage and so avoid at any period a waterlogged state.

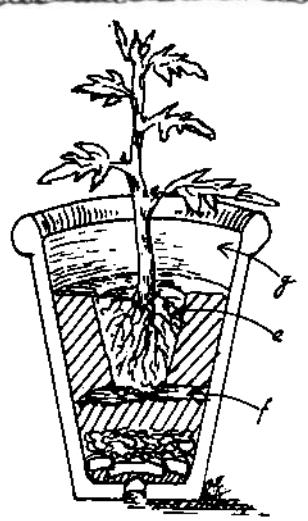
Training.—It may seem superfluous to suggest the training of shoots, but started early it is not a difficult matter to tie them carefully to the wires under the roof, which is preferable to allowing them to grow in any conglomerated fashion.

Watering.—This is a matter of importance, so much so that the pots containing the plants should be placed where they are easily seen and attended to. The general rule for plants as growth proceeds, and weather becomes warmer, to be more liberal with water, holds good in the case of clematises in a cold house, and ventilating on every favourable opportunity must not be lost sight of, particularly when it is remembered that they are of a hardy nature.—CLAREMONT.

Early Tomatoes in Warm Houses.

ALL cultivators of tomatoes know well enough how the young plants thrive in a temperature of about 75 degrees—about summer heat. They also know how difficult it is to get the plants past the seedling stage to the flowering of the first truss when artificial heat is deficient. We all are anxious to begin the work of growing tomatoes, but to those who do not possess well heated structures I say, wait a few weeks longer until the sun's rays are more powerful, then the seedlings will make good progress and soon surpass the earlier, stunted ones. The initial mistake is, generally, that of sowing the seeds too thickly and in soil that is too fine. Great care should be taken in the preparation of the seed pan, or pot; also, in the preparation of the compost. The pan must be well drained, clean and dry; and the compost should be a simple one, containing no manure. Press down the compost firmly and evenly with the fingers, level the surface, make tiny holes 1in. apart and about half an inch deep, water through a rosed watering can. One hour later drop one seed in each hole, fill with soil, do not water, place the pan on a stage in a warm position and cover it with glass and paper. All necessary watering afterwards should be by gently immersing the





pan in tepid water. Gradually expose the seedlings and prepare to transplant them singly, in small pots when each one possesses two rough leaves. Seeds sown at 1in. apart produce stocky seedlings that are quite easy to transplant. High shelves are not suitable for early plants; a stage about 3ft. from the roof glass is a better position. Have some nice, lumpy, fibrous loam in the house, warming and in readiness for the next repotting. The letters *a* and *b* show the drainage and compost in the pan; *c*, the tiny holes 1in. apart; *d*, space for seedlings to grow in without touching covering glass; *e*, the stage of root formation when final potting is done; *f*, rough compost; *g*, space left for top-dressing material. When the young plants are planted in a border for fruiting, provide, at *h*, rough compost and rotted manure; at *i*, fibrous loam without manure. The roots, *j*, being clear of manure in their early stages. All composts should be well firmed.—G. G.

Painting the Greenhouse and Frame.

IT is very important to paint a greenhouse or frame at regular intervals if the structure is to be kept in a good state of preservation. The work does not present any great difficulties, although it is important to bear one or two points in mind. Never paint a surface which is not dry and never do the work in frosty weather, as the paint is sure then to blister and peel off. If the surface has been coated with paint some time previously, remove all loose bits such as are not likely to adhere to the wood. If time can be spared the surface will be improved by sandpapering or light scraping with a putty knife. Work the paint well in, especially if the wood is new. Never employ any kind of preservative, like creosote, for the woodwork inside a greenhouse. It is even a good plan to remove all the more delicate plants before applying ordinary paint. If any fungi or moulds have attacked the wood it is wise to mix a teaspoonful of carbolic acid with each pound of paint. Full up any holes or the cracks in the wood with putty and renew any putty that has come away from the glass. It is important to leave no cavities in which water can stand, as should this happen serious rotting of the wood is likely to set in

Potting Composts.

DURING the next three or four months a vast quantity of "compost" will be required by all gardeners. The basis of all composts is loam and the best loam is a turfy, fibrous earth, which has been stored for some time. Turf from old pasture, cut and stored a year, cannot be improved on; this is the time to make a turf heap for next year. Loam from a garden will serve—often has to serve—but it should be soil from a plot "in good heart," well manured for the last crop and not exhausted, harsh or clayey. Amateurs in the towns who cannot procure turf normally may buy it from a nursery in bags, but the cheapest plan is to buy a cartful and store; it keeps for years. Sand is also required, a nice clean and sharp sand; builder's sand is, as a rule, quite all right, but it is found that almost any sand of normal nature serves. Leaf mould is obtained from rotted leaves which are rubbed through a small sieve; for seedlings it ought to be fine (¼in.), but for pot plants it may be coarser (½in.). The great point is to have the material thoroughly decayed, so that it crumbles easily into a fine earthy matter. That from oak and beech leaves is best, but good seconds are mould from elm, lime, and other leaves without hard stalks and thick midribs. Manure for potting composts is best dried and then passed through a half-inch sieve; it must, moreover, be well decayed, so much so, indeed, that the litter in it rubs down into fine fibre. Cow manure, horse manure with straw and pig manure are best. Old mortar consists of the refuse from house demolition, ground or tramped fairly fine; it consists of sand mixed with a very useful form of carbonate of lime (chalk). Ground limestone or chalk may be used in place of it or finely ground shells, in some cases. One thing more—charcoal; many neglect this, but we have repeatedly demonstrated that it is one of the finest things to use, not only to keep the soil sweet, to conserve its manurial content and to ensure porosity, but also to remove chances of suffering from that dread disease, "damping-off." Grind a quantity saved from the bonfire by tramping on it, and stir the coarse powder into all composts.—CLYDESDALE.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT.

Leaves and Bracken.

Large quantities of leaves and bracken should be carted to the shrubberies and spread evenly over the ground among rhododendrons, azaleas, viburnums and berberis, which respond well to heavy mulching. Dry banks and slopes planted with shrubs should be liberally treated, and, to prevent the wind from blowing the leaves about, spread a thin layer of bracken over the leaves; this will hold them in position the whole season. Bracken by itself is a splendid material for mulching: it has no equal for plants growing on peat or sandy soils, and where plenty is available a quantity should be cut about the end of July and thrown into flat heaps so that rain can penetrate into it. By November this will have become partially decayed, when it can be broken up short and used for mulching young trees and shrubs. This autumn mulch will help to retain moisture and will destroy most weeds that persist in growing between shrubs.—H. W.

The Maidenhair Tree from Cuttings.

Although plants of this peculiar tree, Ginkgo biloba, are usually grown from seeds imported from abroad and said to be the only means of increasing it. Plants may also be grown from cuttings, if taken at a favourable time, in spring, before growth commences. Short jointed cuttings taken off in late March or April and inserted in sand in a cold frame, or covered with a bell glass and shaded from bright sun, will emit roots before the end of August, when they should be transferred to small pots. Partly to sever the cuttings at a socket, or joint, by a gentle pull and allow them to hang on the tree until the wound is healed over, or forms a callus, will be found to be even more successful than the former method. The cuttings will be none the worse, and they will emit roots more quickly after being placed in the sand, than if they had been freshly cut and smoothed with a knife.—W. G.

Propagating Rambler Roses.

When rambler roses arrive from the nurseryman, cut the stems down to about 6ins. in length before planting. This will allow the strength of the tree to go to the root and you get much better results than if the growth had been left. Insert the cuttings in sandy soil, and you will find that even in November or December, if the ground is not hard with frost, they will take root and make good trees in a couple of years. Two beautiful new ramblers that lend themselves to this treatment are Albertine and Papa Ronillard.—E. M. S.

Making Carnation Cuttings.

I find it a good plan when making carnation cuttings to split them up from the base to the first joint and put them in a bucket of water for an hour or two, and then the base of the cutting where it was split will have turned outwards. This will allow the sand and soil to get in between more easily. I find that cuttings, treated thus, root better and have more roots than if they are put in as soon as split.—H. S. B.

Fastening Climbers.

Much time is gained if fasteners can be prepared beforehand. Take an old legging, boot or other leather article and cut strips about 1in. wide. Cut these into varying lengths from 2ins. to 3ins. Punch a hole each end. Through one of these holes pass a piece of soft wire, bent hairpin fashion, then bend over the ends and bring them through the loop and pull tight. When using pass the leather round the stem and bring the two strands of wire through the unengaged hole, thus encircling the stem with leather. Fasten the wires then to trellis, nail or other support. You will be surprised at the amount of fastening up that can be done in an afternoon if this system is adopted, and the fastenings are safe and comfortable.—N. D.

Planting Trees in an Old Shrubbery.

The following method adopted by my father has proved so successful that I think it worth putting on record. When he wants to plant one of his cherry trees (or any other kind) in a shrubbery fully occupied by long-established shrubs and trees, he gets an old raisin barrel from the grocer, knocks out the bottom, and digs it into the ground on the desired site. The walls of this barrel enable the roots of the newly planted tree to get thoroughly established before the staves rot, in about two or three years time. He has succeeded in establishing trees in this way in places where it would otherwise have been impossible to do so.—A. I.

Killing Wood Lice.

This pest is very destructive in cucumber and melon houses. To get rid of it procure some pure liquid ammonia, mix at the rate of ½ pint to 1 quart of water and sprinkle on the floor of the houses, closing all ventilators. This applies only to houses cleared of all plants. Take care that the fumes do not reach any adjoining structure containing plants, or the latter will die with the wood lice or any other creeping thing that may be underneath the stages.—F. D.

Eradicating Red Spider on Tree Carnations.

Procure a sheet of corrugated iron and place near a water tap with a hose pipe attached. If no hose pipe available a good syringe with a jet fitted will do as well. Slightly raise one end of the tin so that the water will run off down a grating, then lay a plant on its side on the tin and commence to spray the plant thoroughly, using plenty of pressure of water. Turn the plant round occasionally so that every part, both the under and the top sides of the leaves, is thoroughly syringed and the minute insects washed away. This is a much cheaper way than using insecticide, and just as effective.—J. H.

WELL ROTTED MANURE

MANURES are animal, mineral or vegetable. Manures are mostly referred to as organic when they come from the farmyard. They are, generally, very beneficial to soils that are deficient in humus. Virgin forests, when cleared, produce fine crops because the soil is so full of humus; full of it, but not sour, so that crops thrive for a time without the application of lime or any other ingredient. Organic manures are sometimes regarded as being favourable to the increase of soil pests, but it is a fact that they materially help to kill predatory insects and vermin—enemies of plant life. All animal and vegetable manures promote the growth of plants; there is an economical way of treating such manures and thus getting the utmost out of them. Amateurs very often are obliged to use a quite strawy manure late in spring. Such manure is not valuable, especially if the summer season is a dry one. Decomposition of strawy manure in a dry medium—the soil—cannot be satisfactory, and so the crops do not benefit, in certain cases the manure does more harm than good. In the autumn fresh or green manure and litter also may be dug into the soil and allowed to remain there all winter for the benefit of spring and summer crops, but, where possible, the amateur should treat his stock of manure before applying it to the soil. The manure should not be left exposed to the weather, especially to rain, as all the goodness will soon be washed out of the heap. I daresay many readers of THE GARDEN have noticed exposed heaps of manure near farm buildings and also where the liquid has flowed down the nearest ditch or hollow, and how luxuriant the herbage is on both sides of the sluggish stream. Well, it all means that the farm land is being robbed of valuable manure. The ideal way is to have the manure covered under waterproof roofs and a big well made near by to collect any liquid flowing. From such catch-pits or wells the liquid can be pumped and conveyed to the land. In the small garden the manure should be under a shelter of some kind and near by there should be a small catch-pit to collect the liquid. How valuable, when properly diluted, will such liquid manure be to the enthusiastic amateur when he wishes to feed his plants.

Moisture must come into contact with dry, strawy manure to cause it to rot. To this end the gardener should sprinkle water on it in moderation, then turn over the heap, always lightly, not in lumps. Fortnightly turnings for about six weeks will cause rapid decomposition, and where it is possible to obtain seaweed the latter will reduce a heap of littery manure to a rotted state in a very short time if mixed with it at the first turning. Rotted manure from any source should be kept cool and dry. In light soils it may be used more liberally than in heavy. Into the latter it may be dug during the autumn, into the light early in spring. Fresh organic manure should not be used for potatoes; rotted it is excellent for this crop, also for celery, leeks, onions and winter greens in poor soils, and for cauliflowers, savoys and cabbages during the summer even in the best soils. Stable manure is best for heavy loams, and cow and pig manure for light. When farmyard manure continues to rot in the soil it also hastens the decay of other organic remains in it too, and in a decomposed condition the manure absorbs moisture in a more beneficial way for plant life than when it is fresh—littery mainly—so I would again urge its decomposition before applying it to the soil, meantime keeping it cool and covered from rains. G. G.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Plants which can be Grown in a Disused Quarry.

Will you please advise me as to what I can grow on the stony sides of a disused quarry and also in the quarry itself, which forms two sides of a rectangle, the third side has a low boundary wall and the fourth is open. There are at present a few trees, yew, birch, Scotch fir and holly, besides a few laurels and lilacs in the space, and I am clearing out the laurel and opening up the place so that the trees can be seen. I am also cutting back the ivy on the stony sides of the quarry and want to plant them with something that will throw masses of flowers over them. There is a certain amount of soil in the crevices. If I can do this and get something to grow under the trees, the effect should be very good. Would you please suggest something? I do not propose to make regular beds, but want the effect of a woodland glade. The place will, of course, be shady, though I am opening it up freely.—J. D. B., Templecombe, Somerset.

You should enlarge the holes in the sides of the quarry to ensure more soil space for the plants. The following would soon form masses, the foliage of some hanging gracefully: Aubrietias, Cerastium tomentosum, Saxifraga umbrosa. If it is possible to provide soil at the top for several plants of Clematis montana, a great deal of wall surface would soon be covered: or the clematis could be planted at the base. Azara microphylla could be used for covering lower spaces. Periwinkle, major and minor, and St. John's wort could both be used to great advantage under trees. Kalmias, laburnum, several flowering thorns, philadelphus, Prunus Pissardii (for coloured foliage) and azaleas should combine to make an effective display.

Alpines for a Small Rockery.

I wish to make a rockery on a piece of raised ground facing north at the foot of an elm tree and shall be obliged if you can tell me the names of the most suitable plants to use and the correct time to plant them. Will laurel cuttings take root if planted at this time of year.—L. W. S., Mill Hill.

The following kinds of plants should succeed on the rockery, namely: Achillea rupestris, Alyssum saxatile, Arabis albida, Arenaria balearica, aubrietia, Campanula garganica, alpine dianthus, Erinus alpinus, Iberis corifolia and Little Gem, Linum flavum, Phlox amœna, Primula japonica, sedums, saxifrages, Veronica repens, Statice incana nana, Silene acaulis. Plant early in spring. It is late to insert cuttings of laurel, but you may succeed if the cuttings are taken with a small "heel" of older wood, inserted in a cool, north border, with sand at the base, and the soil kept firm around the base.

Materials for Path Making.

I shall be glad if you will advise me if crushed bricks will make a satisfactory path, screened about as fine as the top-dressing of a hard tennis court. Kindly say if this would "pick up" after frost, and if liable to grow green.—W. P. S., Droitwich.

All loose material, from soil to cinders, picks up after a thaw unless the thaw comes with heavy rain. Ashes and brick dust do not pick up as much as gravel, because they are more porous and become dry sooner. If you roll down the brickdust path very firmly it should make a really good lasting path on which moss or green matter will not form as freely as on a gravel one.

Mushrooms and Rhubarb in a Cellar.

I should very much like to try to grow mushrooms in a wine "cellar" (so called, though it is not underground), and as I am entirely ignorant of what is required, I should greatly appreciate it if you would give me full directions. The cellar is perfectly dark and dry, and as hot-water pipes run through the upper portion, the temperature is round about 55 degrees Fahr. I propose growing the mushrooms in boxes; how deep should these be? Should the stable manure have any loam mixed with it or any placed on top? How far apart and how deep should the spawn be planted? Will you also kindly tell me exactly how I could force rhubarb in this cellar.—H. S. H., Hampstead.

You will need some fresh stable manure, collected every day, spread out thinly in an open, dry shed, and turned over daily, to allow the rank gases to escape. When about ten barrow loads have been collected, make up the bed—on the floor preferably—and tread down the material firmly as the bed is being built up—18ins. at the back, 12ins. at the front. When the heat is declining and registers about 85 degrees, insert the lumps of spawn—2ins. square—9ins. apart and 2ins. deep on the surface. Put on a layer of maiden loam—from a pasture for preference—2ins. deep and cover with clean straw. Do not put soil with the littery manure, and do not water. Keep in darkness and avoid cold air. The rhubarb roots may be packed in fine soil close together on the floor, and watered once. Growth will soon commence.

Fruit Varieties for a Small Garden.

I am taking over a new house in Wallington in January and I wish to plant a few fruit trees, etc., now, and ask your advice as to which I should choose. The soil 2ft. 6ins. down is chalk. I require about four eating and cooking apples, about three or four eating pear trees, about one eating cherry tree, about one plum (eating). I thought about two dozen raspberry canes (Lloyd George, Laxtonberry), also about fifty strawberry plants, whichever you select for me, also a few black and red currant bushes.—W. C. H., Tooting.

We think the following varieties would suit your purpose quite well: Dessert apples: James Grieve, Ellison's Orange and Egremont Russet. Cooking apples: Rev. W. Wilks, Stirling Castle and Newton Wonder. Dessert pears: Conference, Louise Bonne de Jersey and Durondeau. Dessert cherries: Napoleon and Governor Wood. Dessert plums: Victoria and Dennistons Superb. It would be best to plant two of each sort of cherries and plums. Lloyd George is the only raspberry you would need to plant, while the two strawberries to go for are Royal Sovereign and Sir Joseph Paxton. For black currants, Seabrook's Black and Goliath will be best, and of the red currants, Perfection and Royal Castle.

It would probably be best to buy half-standards or standard plums and cherries, and to plant these as a sort of "break" or screen along the bottom of the lawn. The apples and pears, however, would be best as bush trees, planted down the pathside as you suggest. Of course, the pears and the apples would do splendidly as cordons along the pathside trained on a simple wire trellis. The strawberries should be given a separate bed away from the fruit trees, but the currant bushes could well be planted between the larger trees.

Plants for a Narrow Border.

Can you tell me what to plant in a bed 30ft. by 3ft., so as to get a good show for next summer. The bed is above a rockery and has a rustic fence with ramblers at the back.—P. J. B., Sidcup.

As the border is a narrow one, you should not attempt to grow tall-growing subjects. Several clumps of herbaceous phlox Coquelicot, delphiniums and medium height sorts of Michaelmas daisies, and the remaining space should be filled with doronicum, Coreopsis grandiflora, Anemone japonica, erigeron, Achillea The Pearl, scabious, gaillardias, with annual larkspur, clarkias, godetias and viola clumps in front. These plants will bear flowers from early spring until November.

Self-Fertile Apples.

I have just purchased a small bush apple tree, asking for a self-fertile variety, as it is the only one in my garden at present. I am afraid the nurseryman has let me down, as he has sent me a Worcester Pearmain. Will you please tell me if I must get another to set the fruit on it? If so, would Laxton's Superb do, or is there a better one?—A. H. W., Buckhurst Hill.

The Worcester Pearmain apple tree is partly self-fertile, but would set better crops if another tree of a different variety were planted close by. Laxton's Superb would do quite well, or failing this, James Grieve.

Liming Soils and Transplanting Shrubs.

I dug over in September and manured with old decayed manure my rose beds and a herbaceous border which I intend to plant early in spring. I wish to know which is the best time to dig in some lime—whether to apply it now or wait until the spring. The beds have not been limed for some years. Soil, fairly light, with gravel subsoil; rather wet in winter. Is it possible to transplant successfully three year old bushes of Spanish and ordinary yellow broom, both about 4ft. to 5ft. high?—S. E. J., Twickenham.

Apply the lime now; do not bury it deeply, but mix it with the surface soil at the rate of one bushel per square rod. Great care must be taken with the broom plants. Secure as many fibrous roots as possible, and stake firmly when they are replanted. If blown about then they will not survive. Keep the soil moist.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2876 Saturday, January 15th, 1927 Price TWOPENCE

AQUILEGIAS, more commonly known as Columbines, form an elegant group of garden plants which cannot receive too high praise for their beauty and usefulness. All are hardy perennials of great merit and should find a place in the border or rockery of every garden, where they are most effective if grown in bold clumps. They are also admirable subjects for all kinds of decorative work indoors. The many fine strains which are now obtainable show a wide range of colour with all gradations of "blues" and "reds," which make for the most charming colour combinations. They are easy to grow. They may be sown under glass this month or out of doors in April and May.

NOTES AND COMMENTS

A Mild Winter and Its Effects.

OWING to the unusually mild conditions which all parts of the country have experienced during the past few weeks, many plants, which according to all the rules of the game should still be in a dormant state, are commencing to push into growth. The crowns of many herbaceous plants are swelling and young tender growths are already tentatively pushing their way through the soil covering. While these will not suffer to any great extent from late frosts, unless they are exceptionally severe, they are open to the greater danger of attacks from slugs at this time. Many herbaceous perennials make tasty bites for slugs, and no plant more than the delphinium. Whole plants may be ruined by slug attack, and all gardeners who grow these handsome border subjects should take every precaution at protecting the plants now by placing round the crowns, which in all probability will be bare of soil, a dressing of sand and fine ashes with a dash of lime to a depth of 1in. to 2ins. This dressing will carry the plants over the trying period and will serve as additional protection to the crowns if severe weather occurs later on.

On the other hand, it is unfortunate that so many shrubby subjects are breaking into growth so early in response to the mild weather. The swelling buds are apt to suffer severely from late frosts, and the health and appearance of the plants are thereby impaired. Do not coddle any of the shrubs in the garden unnecessarily and thereby hasten them into premature growth. Rather retard them slightly until we are more or less sure that all danger of really hard weather is over. The winter jasmine is now at its best, and many a house front looks exceedingly well with its drapery of bright yellow blossoms. The witch hazels are bursting into bloom, while fat flower-buds are showing on Daphne Mezereum, the Cornelian cherry, the corylopsis and many of our early-flowering hardy heaths following on their winter-flowering relatives. These hardy heaths make a most brilliant show when planted in colonies, their bell-like pink and white blossoms borne so profusely and their neat, compact clumps of foliage being much appreciated in bare corners of the garden. There are any numbers of other shrubs showing signs of early flower, and gardeners should make a note of any plant which strikes them as worthy, and, if possible, include one in the spring planting scheme to brighten the garden next winter.

Not only should a look-out be kept for isolated flowering subjects, but keep an observant eye for attractive flower and shrub groupings at this time of year. Not so long ago we noticed a very effective association of winter aconites and the dogwood. The aconites were in full flower and looked extremely well against the background of the brilliant red stems of the dogwood. The dogwoods are a valuable and useful group of shrubs, as many of them are as handsome in summer with their variegated foliage as they are in winter with their richly coloured bare stems. There are innumerable combinations one can have with winter-flowering plants, and the gardener who is observant will learn much to his advantage by a walk round many of our public gardens at this time.

To Secretaries of Horticultural Societies.

AS has already been mentioned in these columns, it has been decided to include in each issue of THE GARDEN a diary of events for the week following that of publication. It is our desire to make this diary of forthcoming horticultural events as complete as possible, so that it may serve as a useful guide to all gardeners in different parts of the country, and in this connection we would again ask all secretaries of horticultural societies who may not have seen our previous references to co-operate with us, and to send in a list of their meetings and shows during this year addressed to The Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2. By this diary of events we hope to stimulate interest in the work of all the local horticultural societies and at the same time to call the attention of our readers to any interesting lectures and shows which may prove helpful to them in their gardening duties. Much can be learned at these meetings and local flower shows, and many of our readers, we feel sure, are interested to know of the activities of societies in different districts and to note the general trend of horticulture throughout the country.

HAVE YOU

¶ *Set up the tubers of your first early potatoes in single layers in shallow boxes placed on a light shelf in the greenhouse? They will soon sprout in this position.*

¶ *Completed the pruning and planting of your fruit trees?*

¶ *Taken more cuttings of your chrysanthemums and geraniums?*

¶ *Sown seed of tuberous begonias, gloxinias and streptocarpus in your warm greenhouse?*

¶ *Made a sowing of broad beans and dwarf peas in one of your frames? After hardening off the seedlings they can be planted outside in April.*

¶ *Prepared your sweet pea trenches?*

Generous Offer to Devon Apple Growers.

IN view of the recent reports as to the probable very serious shortage of apples to meet the ever-growing demands for Devonshire cider, the offer recently made by Whiteways of Whimple is a very practical step towards encouraging the fruit industry in Devon. At a very largely attended meeting of the farmers, fruit-growers and cider merchants recently held under the auspices of the Devon Agricultural Association at Exeter, Mr. Henry Whiteway announced that he would give farmers who were regularly selling his firm their cider apples ten trees for every hundred they planted.

The growing of cider apples in Devon is a very important and profitable industry. According to figures put before the meeting, there are already nearly 25,000 acres of orchards in that county. Any scheme by which this acreage can be increased is of enormous benefit in the present rather depressed state of the agricultural industry and to a certain extent will assist in the promotion of apple culture in this district.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 7, which appeared in our issue of January 1st, have been awarded to

Miss E. H. Lyster,
Crofton Grange,
and **Orpington, Kent.**

Mr. R. S. Gepps,
6, Rue Taillade, Colombes,
Seine, Paris.

To each of whom a cheque for that amount has been sent.

We are indebted to Messrs. Sutton and Sons of Reading for the use of the illustration of aquilegia which appears on the front cover of this issue.

GROW SWEET PEAS IN THIS YEAR'S GARDEN

There are few flowers which can be used with such beautiful effects in the garden as the sweet pea. They are easy to grow and all gardeners should prepare for a summer show of these lovely annuals by sowing seeds during the next few weeks.

HOW often we overlook the great value of sweet peas for garden decoration, regarding them simply and solely as excellent and generous providers of cut flowers for the home. Yet, given suitable treatment and judicious choice of sites, they will fulfil the dual rôle, and there are few subjects which will surpass sweet peas as border plants.

Where to Grow.

The line of division between the kitchen garden and the flower garden sometimes presents a problem which a row of sweet peas will solve. Such a hedge is not, of course, permanent, but the fact that it may be moved every year, if necessary, is not without its advantages. Planting sweet peas in rows may be considered rather too formal a method if one wishes to bring out their full artistic value, and the most effective method, it will be found, is to plant in rings or clumps about 18ins. in diameter, six or eight plants to each clump. There are many positions which such clumps will fill admirably, but in choosing sites one should not forget the height to which the plants will grow and its relation to their immediate surroundings. Clumps of sweet peas naturally lend themselves to the back of the annual border, here and there in the perennial border, at intervals on either side of paths, both in the flower and kitchen gardens, or between the uprights of the rose pergola. They will give a bright and welcome splash of colour along the edge of the shrubbery or in narrow borders right against a sunny wall of the house or garage. In spite of all that has been said and written to the contrary, modern sweet peas are *sweet* sweet peas still, and their delightful perfume in favourable weather conditions will add to their other attractions when planted near windows of the house. A beautiful effect may be obtained by placing clumps in small beds on the lawn, relieving any bareness round the base of the plants with a "carpet" of violas or some other free-blooming and showy bedder.

A ROW OF SWEET PEAS MAKES AN ATTRACTIVE SCREEN BETWEEN THE FLOWER AND VEGETABLE PLOTS.

Sweet peas are invaluable as screens for unsightly outhouses, for covering fences and trellis work, or even the wire of a fowlrun, their lengthy flowering period giving them a decided advantage over most other climbers where brightness is needed rather than permanency.

Even when garden space is so limited that there is little or no room for the Queen of Annuals, small tubs, large pots or deep boxes may be utilised, crocking their bottoms to facilitate drainage and using a fairly rich potting medium. Plants grown in this way will need fairly frequent feeding with liquid manure and soot water, but when in full bloom may be moved to positions it would otherwise be difficult to fill.

How to Group.

After selecting appropriate flowering quarters for our sweet peas, the next consideration is their colours. Always we should bear in mind the immediate surroundings of the plants and endeavour to choose colours which will harmonise with these, or present a pleasing contrast. We may strike out a mixture of varieties as out of the question. For clumps, the rule should be one colour one clump, unless one's taste inclines to two harmonising shades. In the latter case, it will be found that cream will blend well with almost all rich, bright shades, such as orange, orange-scarlet, scarlet, scarlet-cerise, salmon-pink, maroon, purple, cerise, lavender or deep cream pink. Whites "go" with almost any of the dark and rather harsh shades, maroon and most other colours which are not on cream grounds. Light blues and lavenders blend very nicely with the lighter cream pinks or the pink blushes. Personal taste will no doubt suggest many other pleasing combinations. Bright or very light colours should obviously be associated with dull backgrounds. Even when planting in long rows instead of clumps, some kind of colour blending or pre-arranged order of planting should be arrived at in which the varieties—although kept separate in the row—harmonise with their immediate neighbours. This most certainly enhances the

THE STAKING OF SWEET PEAS IN THE GARDEN OFTEN PRESENTS A DIFFICULTY TO THE AMATEUR GARDENER.

Pea sticks make a most effective method of staking and afford considerable protection to the plants themselves when young.

Digitized by Google

colour effect taken as a whole, each variety then appearing to the best advantage.

Culture.

Just a word or two respecting culture. This will be found very easy if one bears in mind the simple needs of the plant. Early treatment of the soil is of great importance. Deep digging or, better still, bastard trenching, 2ft. to 2½ft. deep is advisable, also the incorporation of a fair quantity of farmyard or other animal manure, or, failing this, hop manure enriched with bone meal. The manure should be well mixed in with the soil, not placed in a layer, and not brought nearer than 9ins. to the surface. A dressing of bone-meal and wood ashes incorporated in the top 9ins. will help the plants, particularly in their early stages. Sweet peas do not like badly drained soil or a shady position. Failing an autumn sowing, the next best method is to sow in pots or boxes in the early spring, say, in February, giving slight heat at the outset to encourage a quick germination, but only until the seedlings are through the surface. Then gradually harden them to cold frame treatment, removing the glass lights except during frosty weather. The great point is to keep the plants hardy and sturdy until transplanting time in March or early April.

Training and Staking.

Sweet peas are climbing plants and need supports, and such supports—where decorative garden effect is required—should be neat. Too often one's attention is caught by ugly supports rather than by beautiful flowers. Where sticks or netting are used, these should, of course, be strong enough to hold the weight of haulm, but also unobtrusive. Lateral growths may, with a little care, be tied here and there to the outside of the supports, horizontally if necessary, so as to hide the netting or sticks and leave no unsightly gaps.

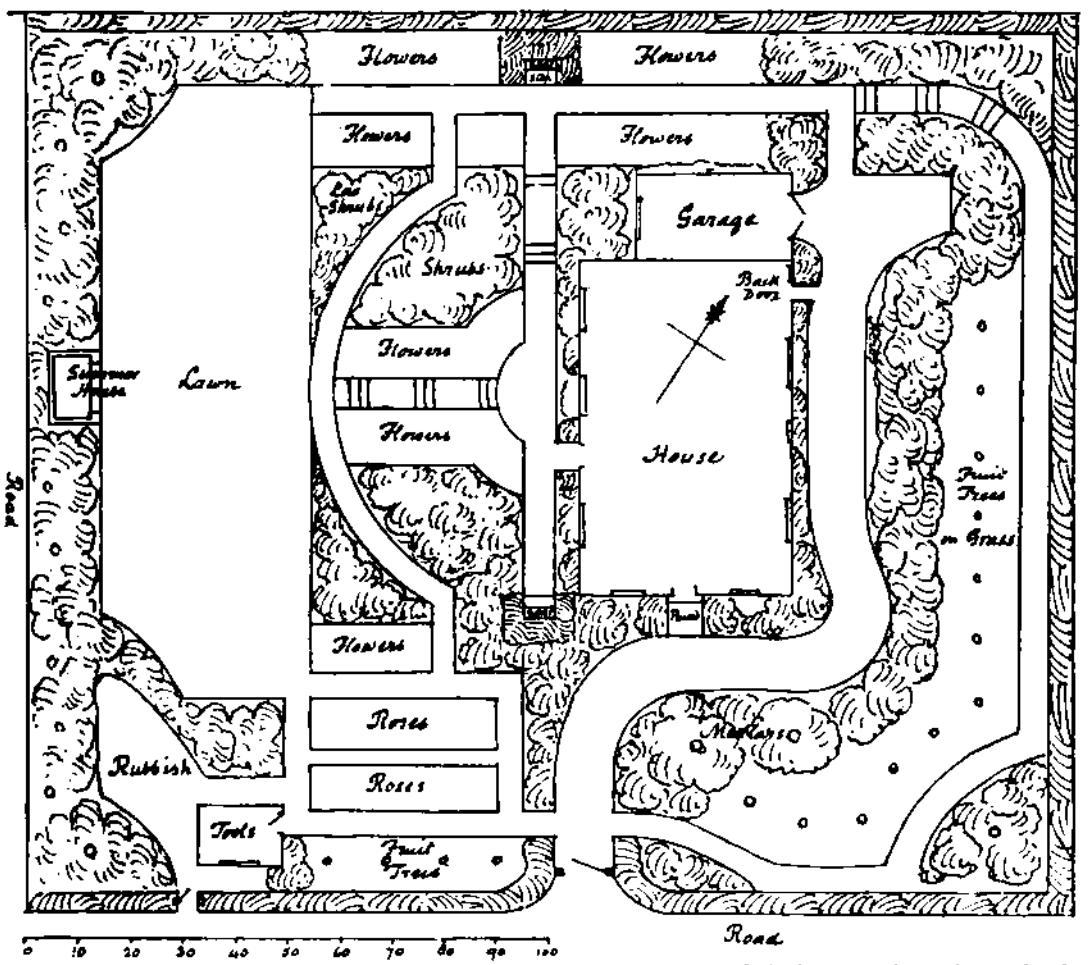
Removal of faded blooms, together with judicious watering and feeding, will stimulate growth and prolong the flowering period, and thus extend the decorative effect in the garden.

C. H. A. S.

THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

THIS is a corner site, and different from some that have been lately considered in that the house is larger in proportion to the ground. This approaches a square, as its measurement is 200ft. by 175ft. The ground is high on the north-east, so that the drive from the garage to the south-east angle of the house is an excavation. An extra space is cut into the higher ground opposite the garage entrance; the returning car will run into this, steering to the right, and can then back into the garage. This space and the near scarp that is parallel with the house will have some dry walling as a retaining wall to the higher ground above. It should be remembered, in such a case, that the walling cannot be built hard up against the scarp, however solid this may be. Builders who are not accustomed to dry-walling are apt to overlook this. There must be a space of at least a foot of loose earth at the back of the stones; then, as each course goes up, the earth is rammed tightly to the back of the stones and partly over them, for some of the stones will be "headers," the better to form a key into the bank. It will have a good effect if the planting round and about at the garage end is all, or nearly all, of one kind of evergreen—yew or box, common or Portugal laurel. From opposite the back door to some way along, the joints and top of the wall will be planted, first with kitchen herbs, convenient for the cook to run out and gather just what she requires of thyme, sage, marjoram, savoury, etc.; then of ornamental flowers, such as catmint, iberis, aubrietia, rock pinks or any of the small flowering plants that seem to be happier in a wall than anywhere else. Then will come a bank of flowering shrubs, and then a row of fruit trees, either in grass or with smaller fruit bushes in cultivated ground between. Nearly opposite the front door, in the widest part of the shrub planting, there would be room for two medlars: spreading, shrubby things, beautiful both in flower and foliage.



Besides the bank at the back, there is a semicircular mass of spare earth in the front highest and even in level with the house above, gradually falling and spreading out fan-shape to the lower level, in front and to right and left; it is from the excavation at the back and the spare stuff from levelling for the house and from the openings for the foundations. This is planned for a double flower border sloping down, and a path between with short flights of wide shallow steps that is raked by a sitting-room window. The path at the top bows out a little in the middle to meet the top flight and runs out both ways to a seat at each end bowered in yew. The ground is made up at the south-east end so that the path goes on the level to the seat, but on its longer way to the other seat there had better be steps. It could, of course, be a sloping path, but steps always have a good effect and the division into separate levels is better as to design; it also saves the path from the tendency of being washed out in heavy rain, which is apt to happen on even a quite slight slope. The foot of the pile of spare earth comes to the semicircular path shown below; the path passes out on the north-west to flower borders, and to the south-east to some rose beds. There are also banks at the lower corners of the lawn, sloping down from the extreme angles to the lawn level. In each of these a good shade tree—oak, lime, chestnut or any tree better liked—will be planted and a belt of shrubs, mostly evergreen, to make a good thick screen from the road. A summer-house will come well in the middle, and is always desirable, not only for its own pleasant use, but also as a definite object to end the garden view from above.

As the line down the steps is not in the middle of the ground, it enables the lawn to be symmetrical and yet to allow of a useful space and the south-west corner for a rubbish place and tool-house. It will be convenient to have a gate here; either a hand gate, or possibly one wide enough for a cart to back in and tip a load of manure.

Biodiversity Heritage Library

THE BUSY MAN'S PAGE

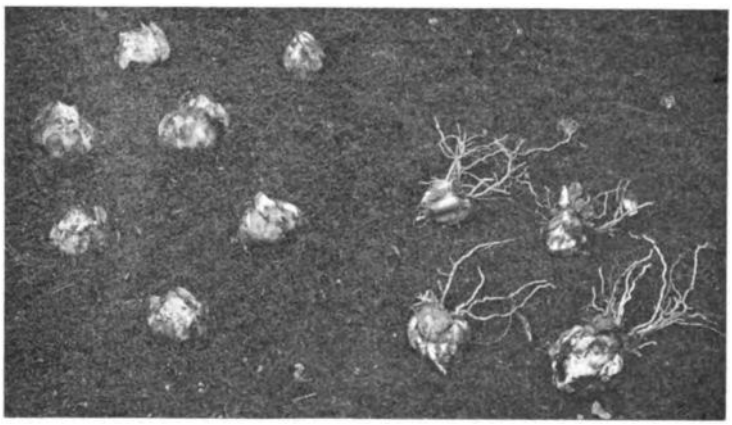
Hints on Planting Lilies.

AS many amateurs will very soon be purchasing lily bulbs for planting, a few hints, most of them hoary-headed, may not be out of place.

Condition of Bulbs.—If the bulbs on arrival are soft and flabby, or have damaged scales, do not plant them at once. Allow them to rest and recover in a box of moist peat or leaf-mould. When the bulb becomes firmer and the roots begin to move is soon enough to think of planting them. Before thus maturing them a good washing in soft water is no bad thing, but after washing they should be excluded from the light till the scales are nearly dry. Before planting, remove all damaged scales, and, if the bulb is of a rare or expensive species, it is not an unreasonable precaution to remove two or three healthy scales, planting them base down in sharp sand and a cold frame. In planting, note that:

(*a*) Except with L. candidum—which should not be planted now—the depth of planting should be three times the diameter of the bulb.

(*b*) All lilies, even the swamp lilies, appreciate good drainage.



THE METHOD OF PLANTING LILY BULBS.

These should be spaced out in irregular groups care being taken to avoid injury to any new fleshy roots.

(*c*) The addition of a handful of charcoal on the top of the drainage is of great value.

(*d*) Each bulb is the better for a good thick waistcoat of sharp sand, and, if good oak-leaf mould be available, do not be afraid of using it, as, generally speaking, it is of greater value than loam, clay or peat.

(*e*) When the lilies begin to grow it is essential to keep a sharp eye on the slugs, which like them; remembering at the same time that the majority of slug-destroying compounds contain lime, a substance unfriendly to most, though not all, of the lilies.

(*f*) It is an advantage if you can manage to consult a recognised handbook on the lily—all have their peculiarities of cultivation and growth.

Helpful Odd Jobs.

AT this time of the year there are many things that can be attended to that will prove helpful later, when, it may be, the cultivator has less leisure. This refers more particularly to the lover of a garden who is occupied from early morning until early evening away from home. We know, well enough, that there are thousands so occupied in every district throughout suburbia. By artificial light in the potting-shed or other outbuilding, or even in the greenhouse, labels, stakes, pots, pans and boxes can be made or mended. The neat little stakes, painted green in readiness for the pot plants and border subjects in summer; the clean pots and pans, new or repaired; boxes; or the heap of pulled turves, sifted leaf-soil and stored sand will all be found most helpful when the days lengthen and the hosts of seedlings, rooted-cuttings and root-bound plants require prompt attention. Indoors, there will be the planning-out of the vegetable quarters; the list of summer bedding plants needed and the neglected seed orders to make out, all to be duly considered; then, when the time comes for dealing with each subject, the work will be facilitated and made more pleasurable.

Bulbs for Greenhouse and Dwelling-Room.

BATCHES of hyacinths, tulips, narcissi, freesias, crocus and scilla bulbs can all be grown from this date without a lot of trouble. The return in the way of blossom for the small amount of labour expended upon them is very great and, if the correct treatment is applied, very satisfying. Unlike some kinds of flowering plants, they can be left unattended longer without harmful effects. Perhaps many readers now possess batches of bulbs in pots and boxes in various stages of development, some being under ashes or sand, where the new leaves and flower stems are forming. It is a fact that numerous cultivators fail to grow bulb flowers with long stems; the latter are too short—stunted—and the flowers on them are stunted too. Usually, this happens when the exposure to full light has been too sudden and at a too early stage of development. A prolonged supply of flowers is obtained by subjecting small batches at a time to the greenhouse heat. When taken from the covering material the exposure to full light should be gradual. If feeding is done by placing the bulb pots in saucers of manure-water all night twice a week, the flowers will be larger and the stems longer. The daily attention will not require more, on average, than fifteen minutes.

Seeds to Sow Now and the Depth to Sow Them.

IN the warm border in the open garden, when the soil is sufficiently dry, the following kinds of seeds may be sown, namely, long-pod beans, early cauliflowers, early cabbage, early sorts of dwarf-growing peas and a few early potatoes should be planted. The beans should be sown about 3ins. deep, the peas nearly 2ins., the potatoes 4ins., the cauliflowers and cabbage nearly ½in. It is a good plan to place a thin layer of dust-dry soil on the seeds before covering them with the ordinary loam. In the cold frame a few seeds of lettuce, carrots, radishes and mustard and cress should be sown and all just buried from sight except the two last named, which must be left uncovered, simply pressed down into damp soil with a piece of flat board. In the warm greenhouse a few seeds of the flowering plants should be sown in pots or pans: cyclamen, ½in.; cannas, 1in.; anthurrhinums, petunias, hollyhocks, verbena, ½in. deep, except the hollyhocks, which should be buried a little deeper. Also sow just a few seeds of cucumber 1in. deep; tomatoes, ½in.; celery, white, merely covered mainly with sand; dwarf beans, 1in. deep. It is always unsatisfactory to sow twice, owing to sowing the seeds at the wrong time, or to lose seedlings through sowing too deeply.

Guarding Against Rose Mildew This Season.

WHERE mildew was present last summer it will be worth while to examine roses at the present time for the purpose of removing any white, woolly patches on the twigs and fruit. These should be cut off where they can be spared and burnt immediately. If their removal is not advisable, the offending "tufts" should be scraped off and the shoots treated with "Abol" or a preparation of a similar nature. With regard to ramblers, it is not an easy matter to overhaul the shoots thoroughly, but as much as possible of the fungus should be removed. It is well to bear in mind that unless the growths of these have been properly thinned, many may be dispensed with entirely; the others may then be more conveniently dealt with. The foliage carries the summer spores of mildew and the disease spreads rapidly at that season, but a great deal may be done in the way suggested in winter to mitigate the trouble.

Some Practical Tips on Growing Vegetables.

WHEN planting cabbages and cauliflowers, carefully examine the roots and stems, for there is sometimes a knot on the stems containing a grub. These plants should be discarded, or the grub destroyed, before planting them. It is well always to puddle the roots of cabbage plants in a mixture of liquid manure, soot and lime.

The ground should be well and deeply dug and heavily manured for crops such as broccoli, cabbages, savoys, cauliflowers, leeks, etc.

In sowing all sorts of roots, such as beets, carrots, parsnips, etc., the soil should be trenched or dug deeply. Well rotted manure may be dug in during the winter, and the more evenly it is mixed with the soil the better. It is inadvisable to give farmyard manure in the springtime to any of these crops because it tends to cause forked roots.

In preparing ground for spring sowings of onions see that it is well firmed. Onions bulb better when so treated. Autumn-sown plants should be planted on deeply dug and well manured plots, but with the soil made firm on the surface. It is always advisable to scatter soot and lime and salt over the onion plot after planting, sowing, weeding or hoeing to keep grub and fly at bay. Have you ever tried winter spraying of the onion-bed with paraffin when digging the soil? It is effective in checking insect pests.

Scatter soot along the rows of peas and it will prevent the sparrows from their customary depredations. Chopped whins put into the drills when sowing peas will keep mice from destroying the crop. Peas, it need hardly be said, should be sown in successional plots or rows. In small gardens it is better to distribute the pea rows here and there, as it takes up less room. If you sow tall-growing peas in grouped rows you must allow 5ft. to 6ft. between the rows. Cabbages that grow about 2ft. high should be in rows 2ft. apart and 1ft. between the plants.

THE FLOWER GARDEN

A Good Rose Species.

ALL through the winter this small species of rose, R. nitida, is attractive and pleasing. Leafless though it is now, it is yet bright, with its red stems and spines, and for a long time in autumn its glossy foliage gave us a wonderful combination of tints. In this respect it vies with the larger R. lucida. Then, in summer, it has small bright rosy pink flowers which are succeeded by round hips of a bright coral red. The plant only grows about 3ft. high, more or less, generally less, unless in strong soil. It will thrive in poor sandy soil and might well be associated with R. spinosissima, the Scots or Burnet rose. With so many good qualities this little rose ought to command a bigger share of favour. It is not an expensive plant and may be planted in autumn or spring.—S. A.

A Fine Garden Primula.

PRIMULA pulverulenta is a handsome and robust perennial, the large healthy leaves proving that it is by no means miffy or difficult to cultivate. The brilliant maroon crimson flowers are produced in whorls on stout spikes, from 2ft. to 3ft. high, these being covered with farina or meal, which renders it distinct from its near neighbour, P. japonica. The best specimens are obtained in damp, partially shaded positions, although if the necessary moisture is available shade is not so important. Fortunately it seeds freely and if allowed to remain a host of seedlings will appear in close proximity to the parent plant, while seedlings can be readily raised on a damp, shady border or in a cold frame. This primula is an ideal subject for naturalising in a shaded moist corner of the garden. Many hybrids, of which P. pulverulenta is one of the parents, have made their appearance in recent years and among the best are Red Hugh, with fiery red flowers and a good constitution, and P. Unique, of a pretty shade of reddish crimson. These are perennial. P. pulverulenta has shown some variation, and the first form to appear was named Mrs. R. V. Berkeley, which is similar to the type, but with creamy-white flowers. There are many damp borders where these primulas would thrive, while shady nooks in the rock garden could be filled with these charming plants. The soil should be a loamy one, preferably on the heavy side, and the planting done now while the roots are dormant.—T. W. B.

Bedding Ranunculus.

ALTHOUGH the three classes of bedding ranunculi are generally listed in every bulb catalogue, they are much too often overlooked when the bulb order is being made out. Of course, they are not bulbs at all; the tubers are quite distinct, but being "lifted" early in summer, they are generally sold and planted along with the bulbs. In the north we prefer delaying the planting of the tubers until we get a few dry days at the end of January or early in February; farther south, disrespect may be shown to the weather by planting almost at any time before that. As with bulbs, initial preparation of the soil goes a long way towards ensuring maximum success later; deep digging and the incorporation of some well rotted manure or leaf-mould, or hop manure, are almost a necessity. Do not plant immediately after digging, but let the ground consolidate for a week or two first. When choosing a site for these flowers, select one well drained and in sunshine; nothing militates against success worse than soil repeatedly and continuously soaked with water, land soured by stagnant soil water. Plant the claw-like tubers with the claws downwards and at a depth of some 2ins.; should the soil be clayey and stiff, draw a trench and fill in with some greenhouse compost, after planting. Tubers which have become dry and shrivelled may, with advantage, be stored over-night in a can of tepid water to hasten sprouting after planting. During March and April hoe the plants regularly to assist aeration and soak them well with water or wash, if droughts are persistent. Flowers will come along with the tulips in May; the colours are very fine and good plants bloom profusely. When the foliage dies down the tubers may be lifted; this is often done too early, to their detriment, but, as a rule, they are ready for lifting in good time to let late summer bedding be carried out—say about the middle of June. Plants frequently seed; this seed may be stored and sown next spring. The three different classes sold are the French, the Persian, and an intermediate possessing the attributes of both these, the Turban. The Persian is earliest, but the French are tallest and most popular.—LANARKSHIRE.

A FEW TUBERS OF ONE OF THE RICHLY COLOURED STRAINS OF RANUNCULUS SHOULD BE INCLUDED IN THIS YEAR'S BEDDING SCHEMES.

THE CANDELABRA SPIRES OF PRIMULA PULVERULENTA.

A Native Cinquefoil for the Rock Garden.

THE rock cinquefoil can claim to be one of the loveliest of our native flowers and the choicest of the indigenous members of its race. In a wild state it is extremely local in this country, only being known to one or two localities, and it does not appear to be widely distributed in the Alps, where it haunts dry limestone regions as it does with us. In the rock garden this is a singularly attractive subject. From a woody, perennial root-stock it puts forth a copious rosette of pale green leaves above which rise the erect and stately 12-18in. flowering stems. These are a reddish orange tint

Digitized by Google

and, branching freely, they bear at their elegantly decurved tips large white blossoms centred with golden anthers. The flowering season extends from June onwards for many weeks. From Corsica comes a very delightful variety of P. rupestris, a pocket edition in the form of P. r. pygmæa. This is a gem of the first water, an exact replica of the type species in miniature, growing to no more than 3–4ins. in height, yet maintaining all the beauty of leaf, flower and grace of the larger plant. Both of these are of easy culture in the rock garden. They do not insist on lime, but appreciate a little. What they do need is rather a dry crevice on a well drained, sunny, fully exposed ledge. Thus accommodated they will live cheerfully and indefinitely.—A. T. J.

A Dwarf Lupin.

(*Lupinus nootkatensis.*)

THE Nootka Sound lupin seldom figures in good gardens, and it must be said that the march of improvement has not been so noticeable with this species as with Lupinus polyphyllus. It is a dwarf species from the Nootka Sound. It is only about a foot and a half high and has spikes of pretty rose, blue and yellow. It is a capital little plant for near the front of the border, quite hardy and satisfied with ordinary garden soil. It may be raised from seeds, sown in spring under glass, or in shallow drills in the open. Plants of good size may also be divided in spring or autumn. It is an excellent little plant.—S. ARNOTT.

CARNATIONS TO BEAUTIFY YOUR GARDEN

In this article will be found a list of modern varieties of border carnations, all of which are worth growing and which can be planted during February and March.

DURING the early part of the winter the temperature has been unusually high for the time of year, and the soil is in an excellent condition for planting. There is no reason, therefore, why carnations should not be planted during the next few weeks if the weather remains open and mild. If transplanted in the open at this time of year they should be made firm, staked if the position is bleak, and the plants regularly examined after frosts to ensure that they have not become loosened. Should frosty conditions prevail when the plants are received they can be potted up, housed for the coming weeks, and transplanted in March.

Choice of Site and Soil Preparation.

Carnations are not exacting subjects. They will stand any amount of frost, but they do not like sodden conditions. Choose an open, sunny situation when selecting a site for them. Soil that is badly drained may be improved by the addition of mortar rubble and strawy manure. Horse litter is best for heavy soils, cow manure advisable for light soils. Lime should be used when preparing the soil if it is not of a calcareous nature. The addition of bone-meal is also beneficial.

The Purchase of Stock.

Well rooted layers, propagated from healthy stock, are cheapest in the end, and the grower is advised to deal with firms whose reputation rests upon the high quality of the goods they despatch. So-called cheap stuff of doubtful quality is dear at any price and not worth garden room nor trouble in growing it.

Varieties of Border Carnations.

There is a wide choice of reliable sorts. Here is a popular selection of eighteen varieties that are not too expensive: Elaine, white; Salmonea, salmon pink; Grenadier, scarlet; E. K. Wakeford, crimson maroon; Mary Murray, yellow; Loyalty, apricot; Purple Emperor, purple self; Mrs. G. D. Murray, white ground marked with violet; Mrs. Edmund Charrington, white with regular lilac markings; Centurion, yellow, barred with scarlet; Enid Lowe, apricot, barred with lavender on rose; Lady Shackleton, yellowish pink, minutely spotted with pink and red; Linkman, yellow, barred with brilliant scarlet; Pasquin, yellow, suffused with rosy pink and lavender; James Griggs, soft grey lavender barred with bright rose; and the four cloves—Fragrance, crimson maroon; Steerforth, white ground edged and splashed with crimson maroon; Mrs. Andrew Brotherston, wine colour covered with minute white spots; and Blush Clove, pale blush pink.

For a larger collection the following may be considered: Mrs. J. L. Gibson, reddish apricot marked with heliotrope, after the style of Kelso but a better grower; Mrs. Horace Lakeman, brilliant rose on an old gold ground, after the style of Rony Buchanan, a good grower and very free; Radio, a distinct and unique fancy, vieux rose splashed and pencilled on a primrose yellow ground; Columbine, a brightly coloured white ground fancy of strong growth; Border Mauve, a fine grower with well shaped mauve flowers; Gordon Douglas, a glowing crimson maroon self; Benedict, a fine deep rose pink self, flowers of fine substance and a lovely colour in artificial light; Ravenswood, white ground heavily striped with maroon crimson; Joan Wardale, a deep crimson of large size and perfect form; Peace Treaty; and Mrs. "T. B.," both lovely fancies of the Linkman type; and Myrtle Pettigrew, a new and novel colour blend of old rose and scarlet.

Perpetual-flowering Border Carnations.

This race is being improved each year, both as regards habit and constitution, and new colours are being steadily evolved. They are perfectly hardy, even in northern districts, and they are more easily propagated from cuttings than border carnations, which are more satisfactory when layered. I have grown practically all the varieties that are on the market and have had good results with them, both in the open and under glass. In addition to blooming during the period when the border carnations are at their best, they throw a later crop of bloom that will open outside if the late autumn months are favourable, but the flowers need protection from rain, mist and hoar frost after the middle of October. Temporary glass protection can be erected around them for this purpose, or the plants can be lifted in the same way as chrysanthemums and they will flower during late autumn and winter in a cold house.

Cultural treatment in the open is the same as for the border carnation and old plants need trimming before winter sets in.

The following is a selection of useful varieties: Highland Lassie, white ground edged with red; Sussex Beauty, deep heliotrope flushed with rosy salmon; Sussex Crimson, deep crimson like the old clove; Sussex Lass, a beautiful shade of clear rose pink; Sussex Maroon, light maroon crimson; Sussex Perfection, white ground flaked with red; Sussex Pink, peach pink, one of the older varieties, but very free-flowering and of good form; Sussex Purple, crimson purple; Sussex Supreme, a beautiful shade of deep flesh pink; and Sussex Scarlet, a brilliant scarlet of the same shade as the old border carnation, Cardinal. Newer varieties of merit are Sussex Flake, Sussex Ray, Sussex Multi, Sussex Tricolour, Sussex Lady and Sussex Sunrise. These form a fine group of bizarres, and the colours are similar to the carnations that were popular in Tudor and Stuart times.

NORMAN LAMBERT.

FLAKED PERPETUAL BORDER CARNATIONS ARE MOST ATTRACTIVE.

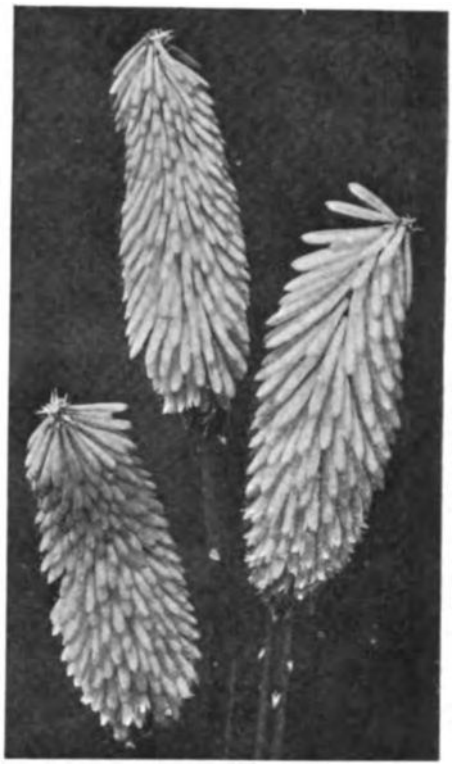
THE FEATHERY PLUMES OF GOLDEN ROD.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.



THE RICHLY COLOURED RED-HOT POKER.

Solidago (Golden Rod). AN old tenant in many gardens, to be seen in all parts of the country. Easy to grow, quite hardy and thriving in soil that cannot always be described as rich, the solidago brings masses of yellow flowers during August and September. It will grow in sun or shade, and varies in height from a foot to 6ft. As a back-row plant for a border it has still many admirers. When so located it should be given plenty of room for development. Division of roots in spring or autumn is best for this old plant.

Statice (Sea Lavender). THE perennial forms of statice enjoy a popularity as being useful for positions in a garden where repeated change is not desired. They are, for the most part, dwarf in character, seldom exceeding more than 2ft. in height, and their flowers, borne in large spreading panicles, are useful for cutting, as they last a considerable time in a dried state. Grown on sandy soil, they are hardy, needing no shelter in winter, but they dislike a cold, heavy soil.

A sunny place on a south border is a desirable spot for the statice, where it should be given ample room for the development of its spreading leaves and flowers. Propagation is usually undertaken from division of roots in late autumn, or from seed sown in light soil in a cold frame in spring, but raising plants in the latter way is rather a long process, and the amateur will be best advised to purchase plants.

Aquilegia (Columbine). AN old-time perennial which needs no recommendation, on account of the beauty of its flowers and gracefulness of its foliage, and by reason of the new long-spurred varieties. No amateur should miss the columbines, as they are of the easiest possible culture and may be planted in either sun or shade. They delight in a soil of a fairly light texture, which has been improved by the addition of rotted manure and leaf-soil. If necessary they can be propagated by division of roots, but they care for little disturbance in this direction, and it is better to increase the stock from seeds, which may be sown in pans of light soil in a cold frame in April or September; but, like other things in a garden, they often produce from self-sown seeds without having to resort to sowing. Average height about 18ins.

Kniphofia (Red-Hot Poker). A VERY popular plant, to be found in all parts of the country, in cottage and suburban gardens alike. It is fairly hardy, soon establishing itself, and if planted in a sunny position never fails with its rich spikes of bloom. Of stately growth, one may, by a careful selection of varieties, have it in flower from June to October. Colours vary from lemon yellow to coral, to flaming red and scarlet. The kniphofia likes a deep, rich and, above all, a well drained soil, which contains a good proportion of well decayed manure and leaf-soil. During winter the grass-like foliage is best tied up to stakes, to prevent the rotting of the crowns which sometimes takes place after prolonged falls of snow. Propagation is from division of roots in autumn, or from seed sown in a cold frame in May in light soil.

Trollius (Globe Flowers). THE trolliuses are hardy herbaceous perennials of the easiest culture. They commence to bloom in May, and continue for several weeks. If, after the first flowers are over, the old stems are cut away, other blooms will be forthcoming later in the season. They will grow in ordinary soil, but best results follow if an addition is made to it of leaf-mould and old manure. They benefit greatly by mulchings of rotted manure or spent hops, approaching the flowering season. They like the sun, but will also thrive in a half-shady border. Trolliuses make a nice addition to a garden where May-flowering tulips are grown, flowering contemporarily with the latter, and are most effective. No amateur should overlook them, for the town garden especially. In the rock garden they are also useful for filling up odd corners. Propagation is best effected by dividing roots, after flowering, or in spring. They can also be raised from seed sown in pans of light soil in spring in a frame, but a couple of years will elapse before plants commence to bloom, hence root division is preferable.

THE SEA LAVENDER (STATICE) IN MIXED BORDERS IS A PLANT FOR ALL GARDENS.

ANNUAL FLOWERS TO SOW NOW

Prepare for a bright display of bloom in your garden this summer by making a selection of annuals from this year's catalogues, and sowing the seed within the next few weeks. A suggested list of annuals, all of which are easy to grow, is given below.

THE present-day gardener has a wonderful range of bedding annuals at his disposal, and gorgeous results can be obtained for little initial expense; indeed, the only expense necessary is to purchase a packet of seed: with labour and a good greenhouse the results are *his* to claim. In the main, seed is sown in January and February; the seedlings are transplanted in due course, grown on for a time in the greenhouse, and then hardened off in the frame. No skill is required; common-sense culture is all that is essential. The subject, fully treated, would be large one, so these notes are confined to a mention of the common things.

Alyssum.—Among the last sown, Little Dorrit, Sweet Alyssum, Silver Queen and minimum are the best. Required for edgings and ribbon designs. All dwarf.

Ageratum.—The low-growing kinds are most useful, although the tall sorts serve for cutting. Little Blue Cloud is a novelty; Dwarf White, Tall White and Tall Blue are good. All grow compactly and neatly.

Antirrhinums.—Sow soon and select colours to suit from the many varieties listed in a good catalogue. The intermediates are 1½ft. and most useful. Dwarf bedders and the Tom Thumb sorts are also good. Mixed seed gives a most delightful blaze of fine colours.

Asters.—The China asters are referred to. Do not sow until March. The Comet is very popular, also the peony-flowered, giant incurved, Victoria and chrysanthemum-flowered. We recommend specially the mignon and the Avalanche sorts. Single-flowered are also exceedingly fine for cutting.

Balsams.—Not often grown, but most effective in the border. Do not plant out till late in June. The miniature sorts, 9ins. high, have remarkably large flowers and look charming.

Begonias.—Sow early to get good plants, and be kind to the seedlings. Not only should the tuberous-rooted varieties be grown, but also Loveliness, Fairy Queen, Crimson Bedder, and other fibrous-rooted sorts. A good strain of seed is most essential.

Clarkias.—Grown in a cool atmosphere and close to the glass these do exceedingly well, flowering freely. Vesuvius, Brilliant, Chamois Queen, Snowball and others are good varieties. Height 21ins.

Cosmeas.—To get the best out of the cosmeas procure the early-flowering varieties and sow early; watch that they do not get drawn too severely. The doubles throw many singles and are not yet fixed.

Dahlias.—Many varieties can be raised from seed, including Coltness hybrids, Cheal's Tom Thumb, collarette, singles and others. Sow at once.

Eschscholtzia.—The present varieties of this flower are all the gorgeous tints of Californian sunsets. Some good kinds are Mikado, Mandarin, Fireflame, Dainty Queen, Vesuvius, Geisha, and so on. They are border flowers simply, and are no use for cutting. Height 9ins.

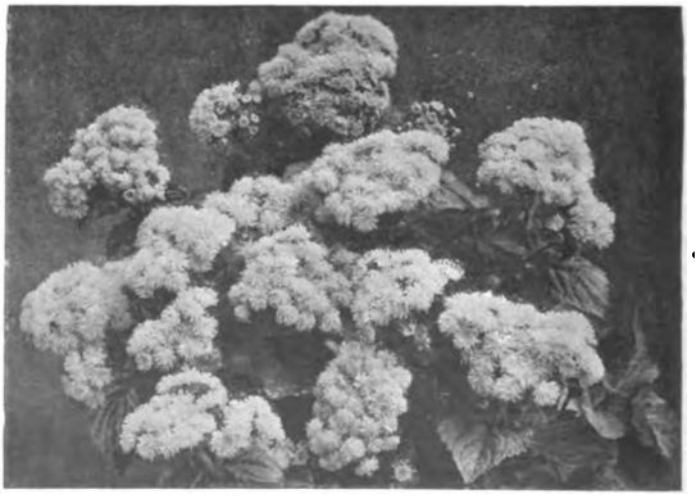
Gaillardias.—These perennials are often treated as half hardy annuals; they are always conspicuous and fine in colouring. Large single, Crimson Glow, The Bride and Lorenziana are very fine. About 18ins.

Godetia.—These are very fine for striking effect in the border, their long, graceful, floriferous sprays being highly decorative. Strong plants will often grow well over 2ft. in height. Crimson Glow, Double Rose, Sunset, Gloriosa, Marchioness of Salisbury, Satin-rose and others are favourites.

Heliotrope.—These are most effective for their sweet perfume. The newer strain Regal, a dwarf, giant-flowered type, is the

AN EFFECTIVE GROUPING OF ANNUAL FLOWERS IN A BORDER. THE ANNUAL BORDER REMAINS GAY OVER A LONG PERIOD FROM EARLY SUMMER UNTIL MID-AUTUMN.

NEMESIAS WITH THEIR BRIGHT AND VARIED COLOURINGS ARE DECORATIVE SUBJECTS FOR EDGINGS TO BEDS AND BORDERS.



THE COMPACT HUMMOCKS OF BLUE FORMED BY AGERATUM LITTLE BLUE CLOUD, A FINE HALF-HARDY ANNUAL.

Digitized by Google

best I know. Height 15ins. Harden off carefully; pinch when 4ins. high.

Kochia.—Undoubtedly useful as dot plants; foliage effect only. Height 2ft.

Larkspurs.—These annual delphiniums are fine for bedding effect against shrubs. Sow early. The Regal strain and the stock-flowered always do well. Both very tall.

Lobelia.—For edging purposes few things equal the fine strains of lobelia now offered. The compacta kinds are most popular, chiefly the blues. The tall ramosa blues are well worth a trial. Lobelia cardinalis is still without rival as a dot plant, particularly the improved forms.

Marigolds.—I have a certain dislike for the African section of these; but the French, double and single forms, are undoubtedly fine. So, too, are the calendulas or Scotch marigolds, like Orange King. The dwarf French sorts are fine for edgings.

Mimulus.—The large-flowered, blotched mimulus flowers profusely in moist borders and is an extremely useful plant to grow.

Nemesia.—Nemesias are indispensable, particularly in the north, as they give a glorious blaze of delightful variation. The large-flowered and hybrid sorts are best. Height 1ft. Grow under cool conditions and only sow in March.

Petunias.—Only really successful in warm sunny gardens, but exceedingly fine there. Double pinks and whites are probably most effective.

Phlox Drummondii.—Less popular than it once was, this must be considered invaluable for bedding purposes. The flowers are very showy. Nana compacta, carminea and other named varieties are choice things to grow.

Salpiglossis.—This is equally good in pots and in beds. It is one of the most ornamental flowers in the border, and a good strain of seed gives very fine colour variation in the large flowers. I again emphasise the value of good seed.

Salvias.—Once grown always grown, may be said here. Fireball and Harbinger are the two best kinds for the border. Height 15ins.

Stocks.—Not only among our sweetest scented flowers, but beautiful in themselves, the different kinds of stocks can furnish flowers through a very long season. The kinds to sow now are the intermediate varieties, including the East Lothian, Covent Garden, Beauty varieties, etc. Later come the ten-week stocks in many varieties.

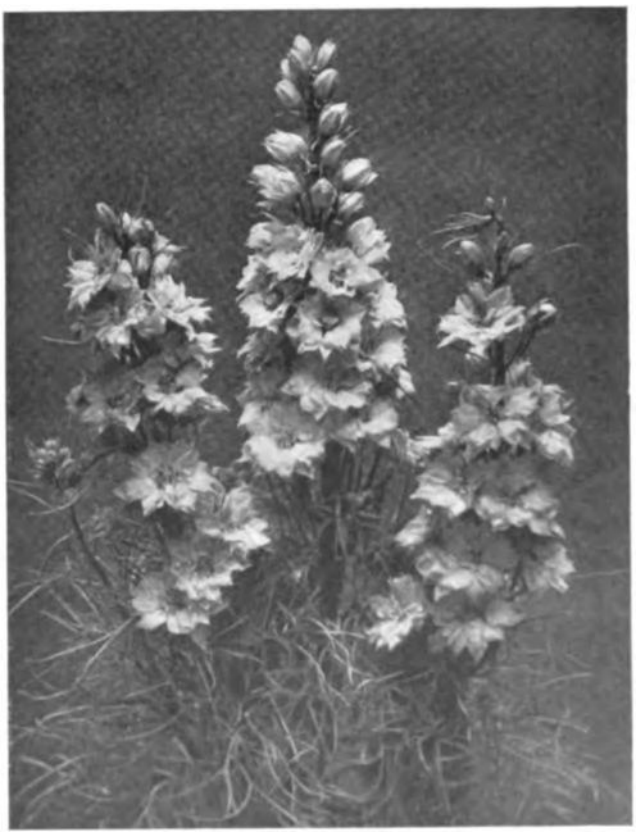
Verbenas.—Verbenas have always been favourites for summer bedding; they must be sown very early, preferably in January for first flowers, with another sowing a month to six weeks later.

Zinnias.—The newer kinds of zinnia, including the giant dahlia-flowered varieties, are receiving more attention yearly and are worthy of it. H. A.

SALPIGLOSSIS ARE EASILY GROWN HALF-HARDY ANNUALS, WHICH LOOK BEST WHEN GROWN IN CLUMPS AT THE BACK OF THE ANNUAL BORDER.

DEEP ORANGE ESCHSCHOLTZIAS PRODUCE A BRILLIANT EFFECT FOR MANY WEEKS IN BEDS OR BORDERS.

There are now many fine varieties of these gaily coloured poppies, and once they are given a corner in the garden they will be grown year after year. All they require is a sunny and warm position to look at their best.



ANNUAL LARKSPURS FLOURISH IN ALMOST ANY GARDEN AND ANY SOIL.

Not only are they attractive as border plants, but they are excellent as cut flowers.

THE FRUIT AND KITCHEN GARDEN

Preparing Ground for Parsnips.

IT was notable last year and during the two recent hot summers that parsnips, grown in a natural sandy, deep soil, were exceptionally clean and large. It was proof that this useful winter root liked a deep, light soil, inclined to dryness on the surface. Although sandy soil is soon dried on the surface, it takes a long time to dry at 9ins. to a foot below the top crust, and it is easy for the tap-root of the plant to penetrate deeply after moisture. The surface, being consistently dry, does not affect the crowns of the plants adversely, whereas a clayey loam does during wet weather, and we have blemished parsnips which do not gain prizes at the autumn shows nor keep for later use in the household. Now, these conditions of weather and soil should teach us so to deal with naturally heavy soils that they will be kindly, as it were, during the summer and early autumn time. In naturally light, well drained ground the seeds should be sown early in February; but in a more retentive soil it will be better to defer sowing until the end of the month, notwithstanding the fact that parsnips require a long season of growth to come to perfect maturity by September. The cultivator should not neglect the first opportunity to trench untrenched ground and to dig sandy soils very deeply; in each case finally dealing with the soil as a body only leaving the surface to be actually prepared for the seeds at the right time. Just at present, leave the top soil in a lumpy state.—HANTS.

How to Obtain Early Supplies of Rhubarb from the Open Ground.

A DISH of forced rhubarb always proves a welcome addition to the menu in the spring. The earliest supplies are, of course, obtained from roots which are lifted and placed in heated sheds or greenhouses.

Many amateur gardeners, however, do not possess the facilities for forcing rhubarb in this manner, and are, consequently, obliged to resort to other methods. The easiest way is to force the roots where they grow in the open ground, and the resultant "sticks," although not as early as those grown in artificially heated structures, are not less luscious.

FORCING RHUBARB OUT OF DOORS WITH THE AID OF AN OLD APPLE BARREL AND A COVERING OF LONG, STRAWY MANURE.
This is a sure and simple method of obtaining early supplies of rhubarb.

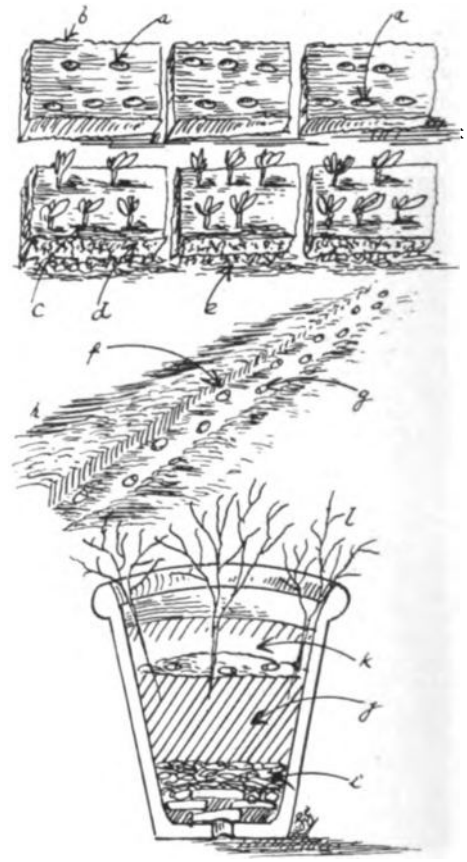
In the absence of specially made forcing pots, all that is necessary is a number of large flower-pots, boxes or small apple barrels—in fact, anything that will exclude light and admit of sufficient head room to allow the rhubarb to grow. These should be inverted over selected roots and the surrounding ground covered thickly with fresh stable manure to keep the roots warm; and if sufficient of this material is available, the whole pot or box may be covered with advantage. Should stable manure not be procurable, leaves may be substituted, although these do not induce such rapid growth. If the top of the box or barrel is made detachable, it will be found much more convenient for examining and pulling the "sticks" as they attain a usable size. Roots treated in this manner are not in any way deteriorated. —T. H. EVERETT.

Growing Onions to Perfection.

THE onion is one of our most valuable vegetables. From its seedling stage to full maturity the plant can be used in the household; instead of discarding the surplus seedlings like those of turnips, for instance, they may be eaten by themselves or in a salad. Some cultivators may be obliged to depend upon spring or box-sown seeds; others may wish to supplement their autumn-raised stock. In both cases box-raised seedlings will be valuable, as the onion plant requires a long season in which to grow and mature. Furthermore, where soils are stiff and retentive of moisture, they are not, generally, in a fit state for seeds to be sown in them before the month of April, whereas there is nothing to prevent the cultivator sowing seeds in boxes or in beds in frames now. The resultant plants will be available for planting out in prepared beds about the middle of April. Thus, we can realise how important a good start is. It means a little extra work, but fine vegetables are not grown without trouble being taken with them—and we all know how keen amateurs are to grow big onions. The boxes must be sound ones—avoid old fungus-infested boxes—about 6ins. deep and not too large, so that they can be easily handled. The best compost is one of maiden loam two-thirds, and leaf-soil one-third, with a fair quantity of old mortar rubble added. Sow the seeds thinly, cover them ¼in. deep. Seeds barely covered with soil produce crooked-necked seedlings and many deformed bulbs. Place loose squares of glass and some paper on the boxes, but gradually expose the young seedlings to full light at an early stage. Do not over-water nor allow the soil to become dry, and the plants will make good progress. The open borders for all onions should be trenched nearly 3ft. deep.

The Raising of Early Beans.

THE bean is a quick-growing plant; is not difficult to manage during the summer months, and yields a good return for the labour expended. The runner bean is not, usually, grown under glass, except in the seedling stage; but the dwarf or French bean is forced very successfully where sufficient fire heat is available. The broad bean is extensively grown from seeds sown outside in the autumn, also from seeds sown under glass. Cultivators who did not sow seeds in the autumn may do so now, under glass, and in a month's time in the open border. The plants raised in the garden frame in turves in the greenhouse or in pots flower and bear pods one month in advance of those raised in the open border. I prefer to sow seeds in turves in which the grass has just died, and have been very successful in the practice. The work entailed is not great. The turves are shown in the accompanying



sketches; they may be of various sizes. Those, as shown, 1ft. long, should contain five seeds. Make holes, as shown at *a*, *a*, in the turves *b*; one seed is sufficient for each hole, then fill the holes with ordinary soil, watering-in the seeds not after they are covered with soil. Place the turves in any conveniently light position, but preferably on a soil base; then the young plants, *c*, will root through the turves *d*, into the loose soil *e*, and when they are transferred to the prepared trenches early in April, they will not be seriously checked, as the turves will be permeated with roots. Seeds should be sown in warm borders in broad, shallow trenches as shown at *f* and *g*, then covered several inches deep with the soil *h*. Early varieties of dwarf beans should be sown in 6in., 7in. and 8in. pots. Good drainage is necessary, shown at *i*, good fibrous soil, *j*, leaving space, *k*, for additional compost; but put some little branching sticks, *l*, in position when the seeds are sown. A summer temperature and a moist atmosphere, careful watering and ventilation are all essential.—GEO. GARNER.

The Care of Seed Potatoes.

WHEN the fruit is gathered from the trees and bushes, the latter are often very much neglected—in fact, forgotten—by many, for a time. It is much the same with regard to potato tubers for planting purposes. They are safely housed from coming frosts in the autumn, and then left in their snug quarters until the time comes for planting. When uncovered, the tubers, especially those of the earliest varieties, are found with long sprouts growing from them. All such sprouts

Digitized by Google

are, of course, useless and are discarded; but a great loss has to be recorded. The tubers are weakened and not capable of producing a big crop, however well they and the soil in which they are grown are treated. Treat the soil well, also the tubers. Begin now with the tubers those that have been quite covered up all through the past early wintertime. Carefully remove all the long, useless sprouts, but retain those that are just beginning to swell, as they will be nice sturdy sprouts about half an inch long by the time they are needed for planting. I have seen such tubers taken into the left hand and vigorously rubbed all over with the right hand, with the result that all sprouts, both good and bad, are rubbed off. Place the tubers in single layers in shallow boxes or on dry shelves in a light position, and by the end of February they will be quite green and nicely studded with stubby sprouts, just the sort that will develop into strong haulm if the cultural treatment is right. Do not retain more than two sprouts on each tuber.—G. G.

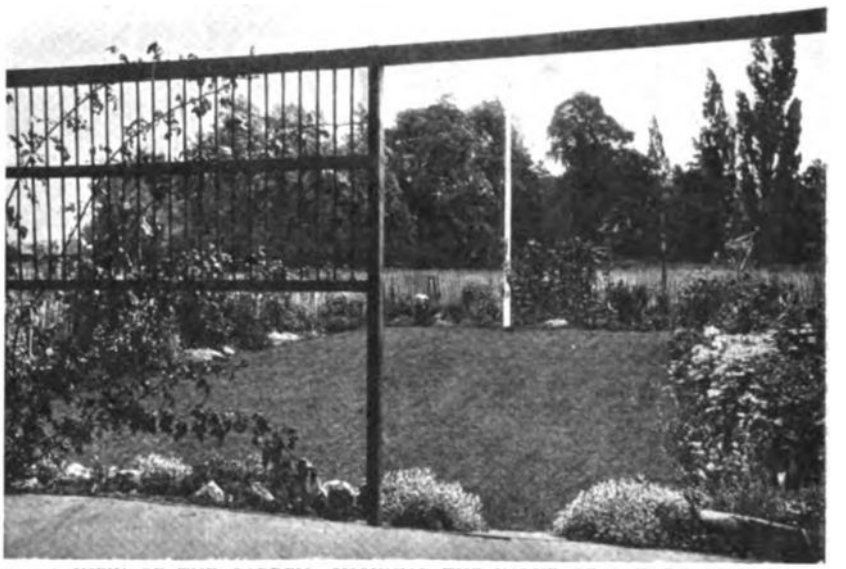
WHAT OUR READERS SAY

THE AUTUMN-FLOWERING FORM OF DAPHNE MEZEREUM.

SIR,—I was reminded by a note which I read the other day that this variety of the Mezereum is still in cultivation. I had lost sight of it for a very long time, and it will be a great pity should it go entirely out of cultivation. It is a good plant for the front of the shrubbery or for the rock garden. It may be called a replica of the ordinary Daphne Mezereum, but flowering in autumn and, in a mild winter, continuing to bear a few of its purple flowers during the dull months of the year. It is commonly sold as grafted plants, but some would prefer those raised from cuttings. Like the double varieties of D. Mezereum, it is exceedingly rare in our gardens now.—S. ARNOTT

A READER'S GARDEN.

SIR,—You are to be congratulated on the recent change that has been made in your paper. With its wide appeal to the small garden owner, I have found it much more helpful and interesting in connection with my own little plot, and as you are now giving designs of small gardens you may like to publish the two enclosed photographs which indicate attempts in gardening during the first year of occupancy. It is the general type of semi-detached villa residence that has sprung up by the thousand during recent years, and when I took over early in the year the ground was just meadow land with a decided slope away from the house; this, I found, was an advantage, as the soil was very heavy clay. I first set to and levelled the ground, which gave me a 3ft. bank at the house end; this, you will see, I made into a miniature rock garden, using a load of large clinkers and broken concrete obtained from the builders. Access was obtained to the house level by a flight of three steps. To cover this rockery simple plants were used—cerastium, arabis, dianthus, etc. This was effectively covered in the first year.



A VIEW OF THE GARDEN, SHOWING THE VALUE OF A WIDE STRETCH OF LAWN SET OFF BY ADJACENT BORDERS.

Above this an unusual type of screen was put to make the garden self-contained; this was built of posts, 3ins. by 2ins., cemented into the ground, and round dowels put through the crosspieces. American Pillar Rose was used as a clothing, and there is every promise that the coming summer will give me a good show. Round the sides and at the end are herbaceous borders, the garden, 35ft. by 100ft., being too small for vegetables, and it being necessary to have as much lawn as possible as a children's playground. The view from the house, as you will see from the second photograph, is quite pleasant — marred, perhaps, by making the mistake of painting the inevitable wireless pole white: but we learn by our mistakes.—H. C.

A MINIATURE ROCK BANK BUILT IN LIMITED SPACE.

PLANT LABELS.

SIR,—"T. A. W." (page 746, December 25th, 1926) is surely pessimistic on the subject of labels. Evidently he has never come across the "Wizard" labels, which solved my problem about four years ago. This label fulfils the two conditions "T. A. W." lays down as necessary for the ideal label—it costs very little, and it certainly lasts for years. In addition, while it is perfectly legible, it is never staring or unsightly.

It is made in two shapes, the one about 5ins. long and 1in. wide. This is similar in shape to the small pointed wooden labels sold in boxes of 100. The other shape—and the one I would recommend, on account of its extra strength—is a small oblong tablet; these are in two sizes—2½ins. by 1½ins., and 1½ins. by 1in. They are fitted either with rustless wire supports for standing, or with loose wire ends for hanging. All the labels are made in a fine quality clay, baked to the shade of a good red brick. The surface is as smooth and easily written upon as writing paper. A

Digitized by Google

waterproof ink is used. After the names have been neatly written and allowed to dry, I dip all my labels into clear copal varnish and allow them to dry thoroughly before exposing them to the weather. For a few days they are unpleasantly shiny, but this very soon wears off. If the larger size is used, there is the advantage of being able to add, in addition to the name of the plant, the country from which it originated, the name of the giver, or brief cultural directions, such as "prune hard in April," "No lime," etc.

Every year, during a spell of warm, *dry* weather, I make a round of the garden with a shallow tin of copal varnish, into which I dip each label, replacing immediately where it belongs. Please note, the weather must be dry, or the varnish clouds. By means of this annual dip the names are preserved perfectly distinctly for years. I have several labels now entering upon their fourth season. —GWENDOLYN ANLEY, *Woking*.

[Our correspondent, "T. A. W.," will find particulars of these labels as described by this writer in the advertisement columns of THE GARDEN.—ED.]

CYANOGAS FOR RAT DESTRUCTION.

SIR,—I have been informed that cyanogas is a very effective rat's bane in outside rat holes. If this be so, I should be grateful for details as to its use. Whether the cyanogas is laid in windward holes and the fumes allowed to drift through the earth, or whether a blower is used. Also, what amount suffices, and if, as in a greenhouse, a temperature of 60° Fahr. is essential for the best results.—J. C.

SCILLA MARITIMA

SIR,—As is well known, the chopped root of this bulb is an admirable rat poison, possessing the great advantage of being harmless to domestic animals. Have any of your readers grown or attempted to grow it in this country, and with what success? If it can be grown, any hints as to cultivation and position would be acceptable.—C. J.

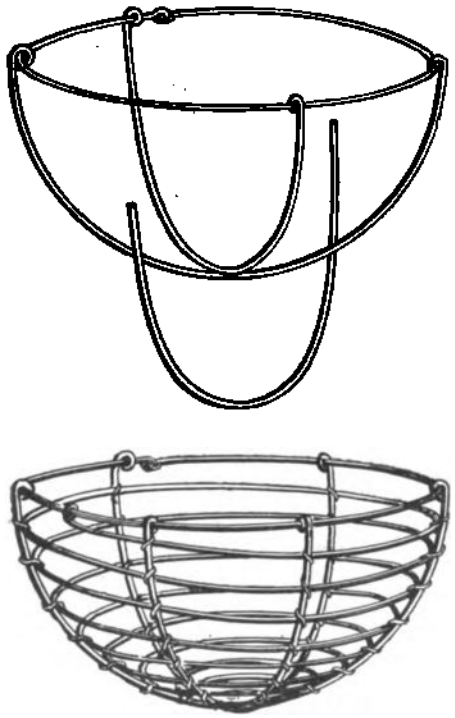
[We should be glad to have readers' opinions on this point.—ED.]

HANGING BASKETS for FERNS and FLOWERS

How to Make and Repair Them.

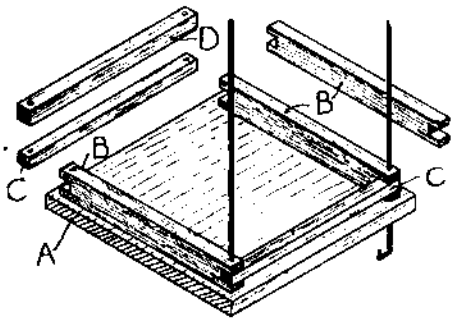
THERE are several methods of making hanging baskets to hold ferns and flowers, the best materials to use being either metal or wood. Ordinary osiers or cane may be utilised, but these materials do not last very long.

Wire baskets are not difficult to make, a typical shape being shown at Fig. 2. It is usual to hang these baskets with three or four lengths of chain. The method of forming the framework is shown at Fig. 1. A suitable diameter is 10ins., with a depth of 5½ins. The wire, which should be galvanised, is



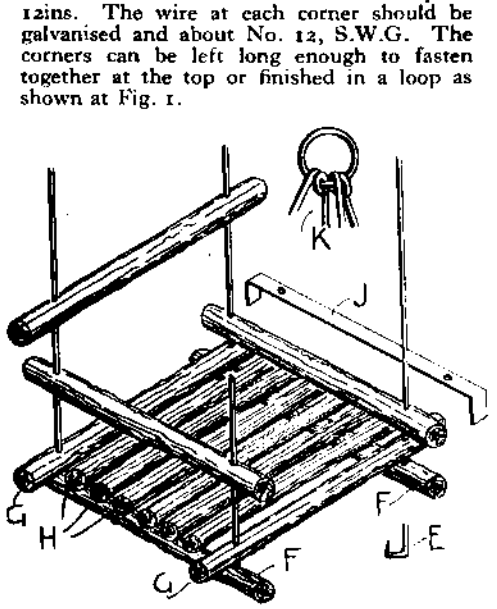
Figs. 1 and 2.—Method of making a wire basket.

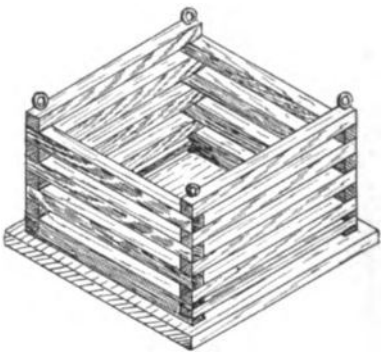
No. 10 S.W.G., will not be difficult to shape if kept in the original coil. When the four lengths composing the framework are joined together as shown, the sides should be filled in with No. 15 S.W.G., commencing at the top as shown at Fig. 2. These pieces should be spaced apart evenly and held in position with No. 18 S.W.G. wire. The whole of the wirework can be done with a pair of flat cutting pliers and a pair of round nose pliers, but extra strength can be imparted to the work by touching the main joints with solder.



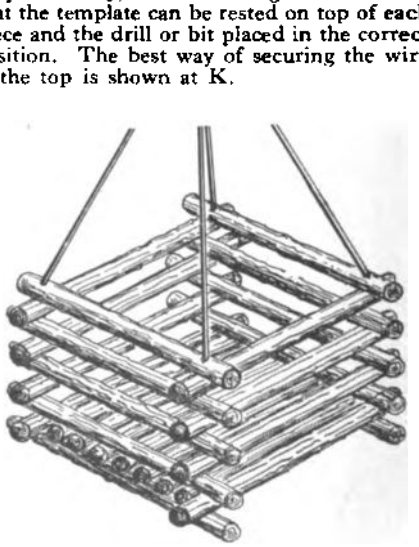
Figs. 3 and 4.—A simple basket made from odd pieces of wood.

A simple form of basket is shown in Fig. 4, it is made from odd pieces of wood with strong wire corners. The method of construction is shown in Fig. 3, the basket being built up with a base A, two fairly thick pieces nailed or screwed across the grain, as at B, two narrow strips which fit into slots cut into the ends of the two side pieces, as at C, and then the sides are completed by a number of strips of square section as at D. The actual dimensions do not matter very much, the particular basket shown at Fig. 3 being made with a base of 10ins. square by ¾in. thick, two side pieces 9½ins. by 1 in. by ¾in., two narrow pieces 9½ins. by ¾in. by ¾in., and fourteen lengths 9½ins. by ¾in. by ¾in. The latter dimensions are suitable for a base up to 12ins. The wire at each corner should be galvanised and about No. 12, S.W.G. The corners can be left long enough to fasten together at the top or finished in a loop as shown at Fig. 1.





A similar form of basket, made from short lengths of tree prunings, hedge trimmings or branches of larch or other trees, is shown at Fig. 6. The method of threading the pieces on the wire supports is shown in Fig. 5. It will be seen that the lengths of wire, about 12 or 14 S.W.G. galvanised iron, are bent at the bottom ends as at E, and are first threaded through four lengths, as at F and G. These pieces project at the corners, but the bottom pieces, H, are cut to the outside length between the two pieces at F and are nailed to them with oval brads or wire nails. With the exception of the bottom pieces at H, the rest of the strips are cut to the same length and bored at the ends with holes the same distance apart. In order to do this accurately, a strip of tin should be shaped as at J, the ends being bent down so that the template can be rested on top of each piece and the drill or bit placed in the correct position. The best way of securing the wire at the top is shown at K.



Figs. 5 and 6.—A similar form of basket easily made from thin pruned branches.

FLOWERS, FRUIT & VEGETABLES UNDER GLASS

Early Cucumbers.

THESE should be grown in a house or pit heated with pipes, then there will not be any danger of a big drop in the temperature during any night, as might happen if a hot-bed under a frame were relied upon. I strongly advise the amateur to try to form a mild hot-bed in the pipe-heated house, because the heat arising from such bed keeps the soil warm and the roots in it, therefore the plants make good progress, because they do not suffer any check. Usually, the most critical stage of the plant is its seedling one. Very careful attention should be paid to the watering. If the young plants are raised in small pots the water should not be poured in at the top. Place some water of a temperature of 75° Fahr. in a vessel and simply hold each pot half immersed in it for about five seconds. The soil in the bottom of the pot will be quite wet and that near the top just moistened—quite enough—and the loss of young plants through damping will be *nil*. The compost in the bed should be 9ins. deep, of fibrous loam and leaf-soil in equal proportions. Plant out at 3ft. apart. Ventilation will not be necessary for several weeks. Stop the leading stem at 18ins. high and all side shoots beyond the joints bearing tiny fruits.—G. G.

Hints on Forcing Vines.

WHERE adequate heat is available, the grape vines may be gently forced now if ripe grapes are required in July. At the present time, with regard to temperatures, a great deal must depend upon prevailing weather conditions. It is not wise to maintain a temperature above 65° Fahr. by day and 55° Fahr. by night during a spell of frost. In calm, open weather the day temperature should be about 70° and the night heat 5° lower. Some cultivators are so placed that they can command stable litter. A heap of this litter placed on the vine border inside the structure will warm the soil and promote early root-action, but, before there is any attempt made in the way of forcing, be sure that the soil is thoroughly moistened. For the first few weeks it will not be necessary to ventilate the vinery; neither is it advisable to syringe the rods except early in the morning of bright days.—G. G.

Grasses for Interior Decoration.

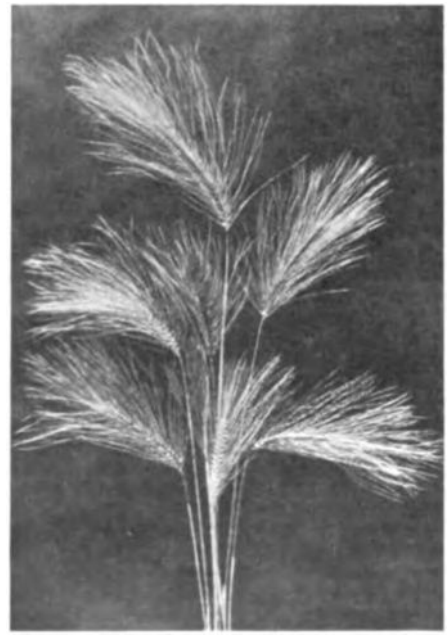
TO introduce some variety into the decorative plants that are grown in pots one might usefully consider the merits of some of the ornamental grasses. Several of our hardy grasses readily lend themselves to pot culture and, with the simplest treatment, will give a very pleasing effect. No heat is needed and the seed may be sown at any time from the autumn to the late spring. The best plan is to sow the seeds in the pots where the plants are to remain. Any good garden soil may be employed, but make sure that the pots are well drained with a good number of crocks, as few of the grasses will flourish in water-logged conditions. Fill the pots with soil, pressing this firmly down until within three-quarters of an inch of the rim. Sow the seed thinly and cover very lightly with soil. Keep the pots in a cold frame, in rather a close atmosphere, until germination takes place. When once the seedlings have started, plenty of air must be admitted to encourage a sturdy growth.

The beauty of grasses in pots depends very largely on proper support being given. A good plan is to insert four sticks at equal distances apart round the edge of the pot. Then pass a piece of stout thread from one to the other, giving it a twist round each stick to hold it in position. If this is done directly the grass plants are 3ins. or 4ins. in height the subsequent growth will hide both the sticks and twine, while at the same time the plants are prevented from falling over.

Some of the best grasses for pot culture are Agrostis pulchella, A. nebulosa and both

THE DECORATIVE HEADS OF THE QUAKING GRASS.

forms of the quaking grass (Briza maxima and minor), Hordeum jubatum, the long barley-like awns of which are of a purplish tint when young, and Lagurus ovatus. All of these provide graceful foliage through



THE FEATHERY AWNS OF HORDEUM JUBATUM.

the whole period of growth and when in flower are extremely beautiful. Seeds of these grasses, in addition to those of other kinds which are interesting, can be obtained from the usual sources.

Plants in Frames.

FUCHSIAS, geraniums and many other plants are often placed in a cold frame during the winter months when there is difficulty in finding room for them in the greenhouse. In these cases damp is usually a greater enemy than cold. Plants of this nature should be kept on the dry side—this does not mean that they should become dust dry—and then there is not much fear that they will be damaged by frost, especially if the glass is covered with sacks or mats in sharp weather. As far as possible any watering that becomes necessary should be given on bright sunny days and in the morning. Then fairly free ventilation of the frames will dispel the superfluous moisture. Water straight on to the soil and avoid wetting the upper parts of the plants. Each day when the weather is mild it is an excellent plan to ventilate freely for an hour or so. When the frames have to be kept close it is wise to wipe away the moisture that has condensed on the glass once or twice during the day, as this dropping on to the plants will keep them in a very wet state. Examine the plants closely at frequent intervals and at once remove any decaying leaves. If these are allowed to remain it is likely that mildew will appear and the trouble may spread to healthy parts of the plants. Plants attacked by mildew may be treated to a light dusting with flowers of sulphur.

Tying and Starting Peaches.

I AM referring to trees growing in heated and unheated houses, and not to those grown on the open wall. Judging from recent experience, I believe that more peach trees are now grown under glass by amateurs than was the case a few years ago. The inexperienced cultivator generally makes three mistakes at this season. The first, failing to water the soil in the border thoroughly; the second, subjecting the trees to a too high temperature to begin with; the third, tying in too many shoots and making the ligatures too tightly. Of course, it is obvious that I advise thorough watering of the border with clear water; that a day temperature of 58° Fahr. and a night one of 50° Fahr. will be high enough until the young buds become active; that there should be a space of at least 4ins. between the tied-in shoots, and that, when tying them to the wires, room should be left for the shoots to swell during the coming summertime without the bark being bruised. Syringing on fine mornings with tepid water will only be necessary during the first week; afterwards and until the fruits have set, damping the paths and borders will be sufficient. If the border is sprinkled over with manure water twice a week and once each week a light dusting of soot is given to the border, red spider will not be very troublesome.—G. G.

Antirrhinums from Seed.

IN order to get the very best results with antirrhinums it is usual to sow seed towards the end of January or early in February. Shallow seed pans are filled with a good porous compost in the usual way; this is watered and allowed to drain; the seed is scattered very thinly on top and a thin sifting of sand and soil mixed is used to cover it. Germination will take place quickly in a warm corner of the greenhouse; whenever the plants are noticed, however, they must be kept on a warm shelf near the glass, well ventilated so that "damping-off" may not play havoc among them. When the plants show their second leaves, they are transferred to boxes of loam and sand; this may be rather coarse in the bottom of the box, but sifted on the surface. It

Digitized by Google

planted 3ins. apart in these boxes, no further transplanting is required. It is usual to pinch the plants later when they are about 4ins. high; this is done shortly before transferring the boxes to the frames in March. During the thirteen years I have grown antirrhinums for bedding purposes, I have tried many different kinds and frankly confess to finding excellent varieties listed by every good firm. Among tall kinds the following are grand—Cottage Maid, Old Rose, Dawn, Orange King, Peachblow, Moonlight, White King, Torchlight and various collours. Intermediates are much more popular—Amber Queen, Enchantress, Morning Glow, Nelrose, Peace, Prima Donna, Fascination, Fiery Belt, Eclipse, Mauve Queen and many others. Of Tom Thumb varieties we would plump for Beauty, Crimson King, Apricot, Ruby and White Queen. Worthy of note, too, are the new compact bedding varieties which have a great future before them.—CLYDESDALE.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

To Wheel a Heavy Barrow Without Fatigue.

Get an old bicycle inner tube, pass it across the shoulders and loop each end over the barrow handles. This, when you stand upright, lifts the barrow legs clear of the ground and takes all the weight off the arms. The "give" of the rubber tube prevents it cutting the shoulders as a rope would do. From experience I find this device increases the barrow pusher's capacity twelve times.—C. H. B.

A Vegetable Marrow Hint.

Heap all the grass cuttings from the lawn in a disused corner of the kitchen garden and leave to rot. About the beginning of April spread over the rotted mowings a thin layer of fine loam or other soil a few inches deep. Insert the marrow seeds in this soil in the first half of April. The plants soon show themselves and make much better progress than if first grown under glass in the usual way. We have never had such a good crop as this year when this method was followed. The rotted grass supplies heat and moisture, and the plants grow at a tremendous rate. Watering can be dispensed with in the warmest weather.—M. H.

Bird Baths.

No garden is complete without its bird bath. It provides our feathered friends with refreshment and gives onlookers endless pleasure in watching the birds' antics while drinking and bathing. We have a shallow bath for small birds, and one a little deeper for starlings and throstles. These bird baths were home-made in the following manner: Mix three parts of coarse sand with one part cement, and make a pliable paste with water. Put this into an enamel bowl (paper-lined) 18ins. by 6ins. in depth. Into this press a smaller bowl, allowing it to remain until the mixture is hard enough to turn out. This forms the bath 1½ins. in thickness. For the base fill a 6in. flower-pot with similar mixture. When hard turn it out, joining the bath and base with cement.—F. L.

Spraying Standard Fruit Trees.

A knapsack sprayer when carried on the back is useless for standard trees; one cannot get sufficient power. Get the wheels and frame of a water cart, two pieces of quartering long enough to reach across the handles, place on these a strong box, nail to the quartering. On top of box place sprayer, fasten a piece of wood each side of sprayer to keep from moving, rope all down securely. Attach 20ft. of hose, wear tortoiseshell goggles, and you then can face the tar-distillate washes and do your tall trees efficiently and in comfort.—W. P. W.

Striking Chrysanthemum Cuttings.

In the following method of striking chrysanthemum cuttings one can be sure of 100 per cent. success. Soak as many pots as are wanted in water all day previous to their being used, stand to drain all night. Although manures are not wanted in striking compost, powdered burnt bones are an advantage, using a sprinkling. After the cuttings are inserted give a good watering and place in a propagating frame on closed stage and put on glass top. The important point is to take this glass top off *every evening* about 5 p.m. *and leave off all night*. In the morning about 9 a.m. sprinkle the cuttings with a syringe and replace glass top, keeping it shut all day. Should the point of a leaf show decay the first day or so, pinch the piece off, but not the good part of the leaf, as sometimes it is already in the tip of the cutting while still on the plant. No other watering will be needed. Seventy-eight cuttings which were inserted on November 30th (one per pot) are now rooting. Warmth in greenhouse only at night.—S. H. C.

Propagating Tuberous Begonias.

Those who want to work up a stock of these lovely plants quickly, and at the same time true, will find the following method well worth a trial. Old tubers should be started in boxes of fibre. These should not be in any way forced, and should be left in the boxes until they are about 2½ins. long. Then with a sharp knife they should be cut off close to the tuber. The cutting should be potted into 3in. pots, using a compost of two parts maiden loam, one part leaf-soil and one part sand. Potting should be done in the following manner: After putting a large piece of crock in the bottom of the pot for drainage, place a small quantity of moss, then fill up with compost to within ½in. from the rim. Dibble a hole in the centre of the pot, and before inserting the cutting put a pinch of sand into the hole for the base of the cutting to rest upon, then insert the cutting and press the soil down moderately firm. Water with tepid water and plunge the pots in a propagating case where a temperature of between 70° to 75° is maintained. When the roots have formed, remove the pots to a cool pit, and as they require more root room repot them into larger pots. Where more plants are required two or three shoots should be left on the old tuber and again propagated in the same manner as the maiden shoots.—J. M. B.

THE MERITS OF DRY SPRAYING

IN a comparison of the merits of dry spraying and wet spraying, no preference can be given to one over the other, although, possibly, through a paucity of knowledge in the case of the former, the other is more constantly in use.

Both have their uses in horticulture to combat the many and varied insect and fungus pests and the diversity of their methods of attacking plants. In the application of the numerous "specifics" concocted and adapted for their destruction, many of these substances, used alone, are too caustic in their action on young foliage and require the addition of others to make their use a beneficial work. For example, the use of paraffin by itself is injurious to plants, but mixed with water and soft soap in the form of an emulsion it makes an effective spray for sucking insects, and if dissolved liver of sulphur be added, an ideal combination spray for insect and fungi destruction is evolved.

The same applies to copper sulphate, probably the best anti-fungicide known and used in most remedies for brown rot, peach blister and other like diseases.

Sulphur.

Flowers of sulphur may be cited as an example of dry spray, and further, it requires a fairly high temperature to be effective, which limits its use out of doors to the months between June and September. Flowers of sulphur will be superseded, I think, by green sulphur powder once the latter becomes better known, owing to it being in a more divided state, thereby coating the leaves with a denser film and increasing the vaporising surface.

Lime.

As a base for the preparation of numerous wet sprays, lime is invaluable, but is in greater demand as a powder spray. To minimise the depredations of slugs on young plants, nothing equals a dusting of lime. Its caustic effect causes them to slough their protective covering—a wasteful process from which they ultimately die.

In mixture with sulphur and applied at intervals from March to May, it will act as a preventive to the spread of big bud on black currant bushes. This preparation is also advised, in the proportion of 2 parts sulphur to 1 part lime, as a preventive of onion mildew; and from experience I can testify to its effectiveness as a sustainer of perpetual carnations against the ravages of rust and red spider.

In parenthesis, may I say that in my opinion wet spraying of these carnations is to be deprecated, for the reason that it denudes the leaves of their protective coating, thereby weakening their resistance against a further infection.

Hellebore Powder.

This powder, which is a poison spray for biting insects, can be used in either form, but owing to its immiscible qualities, is best applied in the powder form, dusting the affected plants or bushes while damp. It loses its poisonous properties on exposure to air, and is therefore valuable where edible plants need to be sprayed.

Tobacco Powder.

Powdered tobacco is a handy form of spray where only small quantities are required, as in application to the tips of chrysanthemums.

It may be said of dry sprays that, being in a form ready for use, a saving of time in preparation and application is effected. Also, it is claimed by their advocates that a greater area can be sprayed at the same cost than could be carried out with wet spraying, for the equivalent outlay.

THE GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2877 Saturday, January 22nd, 1927 Price TWOPENCE

ZINNIAS are among the most gorgeously coloured of our half-hardy annuals. With their large cushion-headed blooms of perfect form and of many fine shades, they make an admirable group of plants for growing in either beds or borders in the garden. They not only make for beauty outside, but they are also excellent for cutting for interior decoration. There are a number of fine strains which take precedence over the old-fashioned types and which are worthy of a place in the garden this year.

WASTED.—Labels as below you write on spot, for Roses, Fruits, Rockeries, etc., to push in, hang, or stand on our Stakes. Twenty shapes, from 4/- 100.—WEBSTER'S, Witheridge, Devon.

LABELS.—Patent metal, so simple to write by a nail; can't fade or break. Trial offer bargain; 100 with 50 stakes, 50 tie wires, 1 pocket nail, 10/- free. Sample 1½d. The R.H.S. use them. Lists.—WEBSTER'S, Witheridge, Devon.

AMATEUR'S COLLECTION OF PERENNIALS, surplus plants, all exhibition varieties, choice flowers, 18 for 5/-; rockery plants, 18 for 5/-. Carriage paid.—F. OLIVER, "Revilo," Long Lane, Ickenham, Uxbridge.

SCOTCH SEED POTATOES.—Finest Certified Stocks. Send for Catalogue and Price List.—W. C. JOHNSTON (Dept. T. G.), Seed Potato Grower, Dumfries, Scotland.

MASKELL'S HOP MANURE.—Best substitute for stable manure, 56lbs., 4/-; cwt., 6/-. Times Guano, the all-round fertiliser, 56lb., 5/-; cwt., 8/6. Ground garden lime, 56lb., 4/-; cwt., 6/-. Screened Gas Lime, cwt., 5/-. Basic Slag, cwt., 6/6. Packed in bags and carriage paid. All fertilisers etc., supplied. Booklets free.—MASKELL'S LIMITED, Dirleton Road, West Ham, E.15.

CHEAP GOVERNMENT WIRE ! ! !—Ideal for training fruit trees, peas, beans, hops, arches, greenhouses, tomatoes, logans, tying, fencing, etc. Strong, flexible, steel stranded and waterproof covered. Several thicknesses from 19/6 per mile (full 1,760yds.). Small lots quoted. Post card to-day for free samples and list of 300 bargains.—GREEN'S GOVERNMENT STORES, 69, Albert Street, Lytham.

BROWN'S TESTED SEEDS.

Illustrated Flower and Vegetable Seed Catalogue, giving full cultural directions, at competitive prices, post free if this paper is mentioned.

THE GARDEN

VOL. XCI.—No. 2877. JANUARY 22, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

The First Show of the Year.

THE opening flower show of the year is one which holds unusual interest for most gardeners. It comes after a lull of a few weeks in gardening activities and serves to remind us that the turn of the year has come and that we may look forward to another and, what we all hope will be, a successful garden year. The first show of the Royal Horticultural Society, held on Tuesday the 11th inst., certainly augurs well for those of the future. The exhibits were bright and varied in nature and on the whole surprising in their excellence for this time of year. The collections of orchids were especially good and the groups of cypripediums and cymbidiums hybrids were particularly striking. Among the more general displays was a fine collection of vegetables arranged by Messrs. Suttons. It was a lesson in vegetable culture and exhibition and a testimony to the productive powers of British gardens and growers. Since the selection of vegetables for the garden must be made within the next few weeks, the exhibit had a certain instructive value in indicating those varieties of vegetables which are suitable for general all-round garden purposes. Exhibits of greenhouse primulas, hyacinths in baskets, carnations, lachenalias and greenhouse plants lent a touch of colour to the hall. There were many exhibits of sundries, which, as usual, hold more than a passing interest for the keen gardener. This year has every indication of being a good show year and all amateurs should make a point of beginning early to visit their own horticultural shows where these commence during the next few weeks. Those gardeners around London should not fail to pay a visit to these fortnightly exhibitions of the Royal Horticultural Society. In Spring the shows are full of interest and the keen amateur will undoubtedly learn much to his advantage by an hour or so spent looking round the exhibition tables.

Heaths at the Wisley Gardens.

THE heath garden at Wisley at the present time is particularly interesting and attractive. Many varieties of Erica carnea are in full flower and the tufts of bright blossom indicate the value of this group of heaths for decorative effect in the garden in winter and early spring. E. carnea is a well known plant and one of the best of the hardy heaths, but at the same time is superseded by many of its hybrids—which have only to be better known to be more fully planted—as they come into bloom earlier and the range of colours is wide and all are most attractive. Among the best at the present time may be noted E. c. King George, a choice compact free-flowering variety and one of the earliest to bloom; E. c. præcox rubra, a charming variety, being of neat habit with flowers of a particularly bright colour; E. c. Thomas Kingcote, an attractive pale coloured variety; likewise E. c. Pink Beauty, which, in the mass, does not impress one much, but on closer inspection shows a pleasant colour. That useful strong growing hybrid, E. darleyensis, also carries a wealth of flower buds, and from the appearance of the groups of this, a great display may be expected in a few weeks. Other heaths at present in flower are E. c. gracilis, E. c. Queen Mary, E. c. J. Backhouse, E. c. Queen of Spain, E. c. Mrs. S. Doncaster, E. c. Prince of Wales. All are worthy of being more freely planted.

Those who are at all interested in winter and spring colour in their garden, should certainly make a point of visiting the Wisley Gardens to see this fine display of flowering heaths. All are plants of easy culture and eminently suitable for the amateur's garden either in the north or in the south.

HAVE YOU

¶ *Made sowings under glass of antirrhinums, lobelia, pentstemons, East Lothian stocks, begonias, sweet peas, etc.?*

¶ *Protected from birds the buds of your fruit trees?*

¶ *Planted a bed of ranunculus?*

¶ *Pruned the roses growing in your greenhouse?*

¶ *Repotted your greenhouse ferns?*

¶ *Removed all suckers from the base of your lilac bushes?*

¶ *Sprayed your fruit trees with lime-sulphur to destroy any hibernating larvæ of insect pests?*

¶ *Patched the worn places in your lawn?*

¶ *Sown a small quantity of onion seed in boxes placed in your warm greenhouse?*

Secretaries.

WE would again ask secretaries of horticultural societies who may not have seen our previous notices to send in to the Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2, a list of their meetings and shows for the coming year. In this way we shall be able to print week by week a complete diary of events in the horticultural world.

R. H. S. Trials.

THE Royal Horticultural Society will carry out trials of annual poppies, sweet sultans, culinary peas (late varieties only, half pint of each required), onions, parsley, sweet corn and beet during the coming season. One packet of each variety should be sent to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before March 31st, 1927.

The Summer Rose Show.

THE Secretary of the National Rose Society informs us that the Summer Rose Show will be held, this year, in the grounds of the Royal Hospital, Chelsea, on Friday and Saturday, July 1st and 2nd. Rosarians should make a note of this date and place of meeting.

The Crossword Prizes.

THE two prizes on One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 8, which appeared in our issue of January 8th, have been awarded to

Mrs. M. E. Sykes,
Dungarth,
Honley, Huddersfield.

and

Mr. T. W. King,
8, Park Terrace, Crescent Rd.,
New Barnet, Herts.

To each of whom a cheque for that amount has been sent.

We are indebted to Messrs. Sutton and Sons of Reading for the use of the illustration of zinnias which appears on the front cover of this issue.

GARDENING ON A SLOPE

Many amateurs whose gardens are situated on sloping ground find difficulty in striking on a suitable design for their garden. Here is a suggested scheme for a small garden which may prove helpful in such circumstances.

IT often happens that the purchaser of a house finds himself in possession of a garden that is inclined towards the building, and in many ways this may be considered disadvantageous, but on the other hand, by judicious planning and careful draining it can be made very attractive and out of the commonplace.

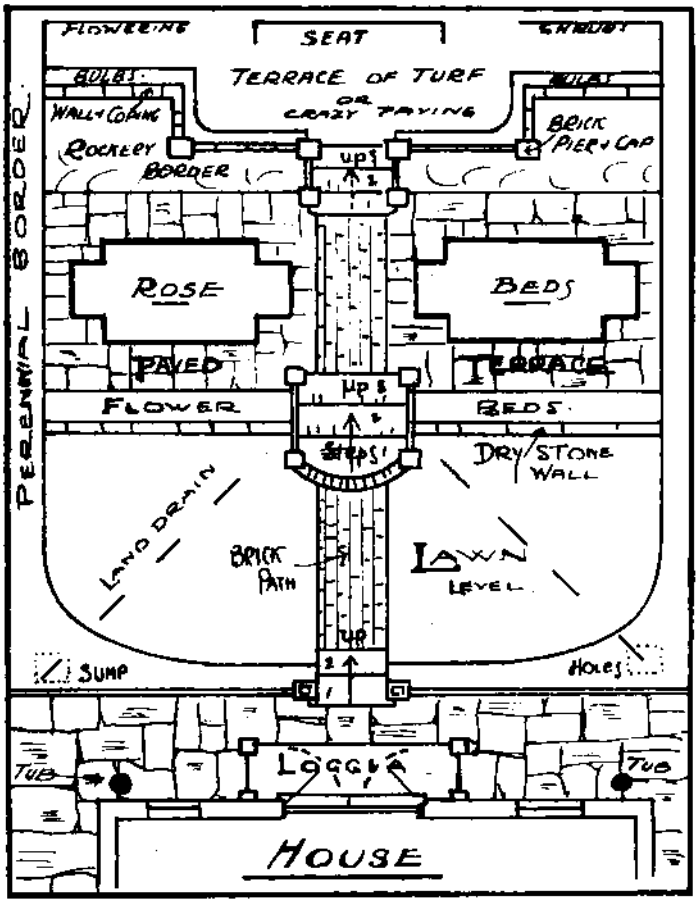
The plan shown can represent the entire garden, if on a small scale, or an inclined path could be formed on one side leading to the kitchen garden or orchard, if the dimensions are larger. Rectangular random jointed paving is shown as a dry walk round the house at the back portion, where standard bays or box trees in tubs would look very well at each corner of the house. A loggia is shown in the centre, but, of course, this could be a conservatory, veranda, etc., according to the style of house and aspect of site.

The first portion of the garden comprises a level lawn, which, in this case, needs carefully draining, not only with clinker or ashes, but with proper 3in. land drain pipes laid to a suitable gradient and carried to sump holes dug in a convenient corner, as indicated. Draining is really essential in a garden of this type and once installed needs no further attention; the sumps should be excavated about a yard square and as deep as possible, with a good layer of some porous material at the bottom; rough clinkers are good, or even old tins or pieces of brushwood tied together can find a final resting place and do good service as a soak-away; the two top spits of soil can then be replaced and planted in the usual way. The ordinary house drainage system will often dispose of surplus storm water, but it is not advisable to rely entirely on this means, but to intercept the water by an independent drain, as described.

The centre brick path arranged to some quaint design, is approached by two broad stone steps, with a brick or stone vase on either side as receptacles for evergreen shrubs or flowering plants; abutting these ornaments a low retaining wall is required and which encloses the perennial border on the one side, the grass edge of the lawn forming the other. The three centre steps are rather larger and more elaborate, and are intended as a distinctive central feature of the garden, with neat red brick piers about 18ins. high, with flat stone caps which provide a suitable place for a bird bath, sundial or even a seat; shallow steps with broad treads are really artistic and always look well in any position, and the crevices may be planted up with various low-growing plants to provide decoration and enhance their attraction.

The next position is in the form of a paved terrace, with rose or other flower beds introduced therein; the particular design of these flower beds can, of course, be adapted to one's taste and requirements; it is important, however, that the beds should be symmetrical and in character with the general surroundings.

The front edge of terrace is devoted to narrow flower beds, where purely bedding plants can be displayed to advantage. A dry stone wall is built on each side of the central steps, where many choice alpine and rockery plants will thrive in the crevices of the stones and look very picturesque; this wall should not be built exactly perpendicular, but battered slightly, *i.e.*, projecting at the bottom thus forming a revetment for the terrace above; this is a very essential factor on loose or made-up ground, as it gives greater strength and a better effect when planted.



A SUGGESTED DESIGN FOR A GARDEN ON SLOPING GROUND.

Two more steps are shown at the top which lead up to a terrace of turf or crazy paving, where seats can be placed if desired or any other more suitable innovation; narrow flower beds are again introduced at the front edge and would be ideal for planting bulbs, etc., for spring flowering. The retaining wall here could have a flat stone coping or a brick on edge as a finish and divided into sections by brick piers and caps as indicated on plan; a good rockery bank or border is formed sloping from wall to the edge of paving, and if suitably planted should produce a very beautiful effect at all seasons of the year.

This scheme can easily be varied to suit the individual taste of the owner, and the particular aspect of the site being developed, the natural slope of the land in question being of primary importance; needless to say the levels should first be ascertained, when the number and depth of the steps can be decided upon; the paths can then be arranged with a slight fall towards the house and a gentle camber in the width, this ensures a dry walk at all times; the joints of brick paths or stone paving should be kept quite open, the natural elements and vegetation will add beauty and colour as the garden matures, giving the whole scheme a very pleasing appearance.

ROSES FOR THE BEDS.

Crimson.—General McArthur, Etoile de Hollande.

Pinks and Salmon Pink.—Mrs. Henry Bowles, Caroline Testout.

Cerise.—Betty Uprichard.

Yellow.—Christine, Independence Day.

White.—Marcia Stanhope.

Use only a few of these varieties, massing, say, two colours which blend well together.

PLANTS FOR THE ROCKERY BORDER.

Alyssum saxatile citrinum; Arenaria balearica; Arabis albida; Aubrietia Dr. Mules and A. Lavender; Campanula carpatica Riverslea, C. Portenschlagiana; Cheiranthus Allionii; Dianthus alpinus, D. neglectus, D. cæsius; Erinus alpinus; Geranium sanguineum lancastriense; Iberis sempervirens; Lithospermum prostratum Heavenly Blue; Phlox subulata; Saxifraga sanguinea superba; S. apiculata, S. Aizoon rosea, S. Elizabethæ; Sedum Sieboldii; Sempervivum arachnoideum; Silene Schafta; Thymus Serpyllum; Viola gracilis, V. cornuta.

PLANTS FOR THE DRY WALL.

Arenaria montana; Alyssum saxatile; Arabis albida; Aubrietia Excelsa, A. Dr. Mules, A. Fire King; Dianthus deltoides; Gysophila repens; Sedum acre; Silene Schafta; Armeria maritima; Saponaria ocymoides.

SOME SHRUBS TO GROW.

Berberis Darwinii, B. stenophylla, Buddleia variabilis Veitchiana, Ceanothus Gloire de Versailles, Forsythia intermedia spectabilis, Philadelphus Virginal, P. Lemoinei, Deutzia discolor flore-roseo pleno, Diervilla amabilis, Ribes sanguineum, Santolina chamæcyparissus, Viburnum tomentosum plicatum, Skimmia japonica, Lilacs Souvenir de L. Spath, Marie Legraye, Mme. Lemoine and William Robinson, Lavenders Wargrave Dwarf and Munstead variety, Olearia Haastii, Spiræa Thunbergii and Veronica Traversii.

PERENNIALS FOR THE HERBACEOUS BORDERS.

Achillea eupatorium, Aconitum Spark's Variety, Anchusa italica Dropmore Variety, Anemone japonica, Asters Climax, King George, Little Boy Blue, Anita Ballard and Barr's Pink; Campanula persicifolia, Chrysanthemum maximum, delphiniums, doronicum, coreopsis, Erigeron Quakeress, Eryngium Oliverianum, gaillardias, Geum Mrs. Bradshaw, Helenium autumnale Riverton Gem, Helianthus rigidus Miss Mellish, bearded irises, Kniphofia Royal Standard, lupins, nepeta, peonies, oriental poppies, phloxes, pentstemons, pyrethrums, violas and pansies. Any gaps which occur can be filled with annuals, dahlias or gladioli.

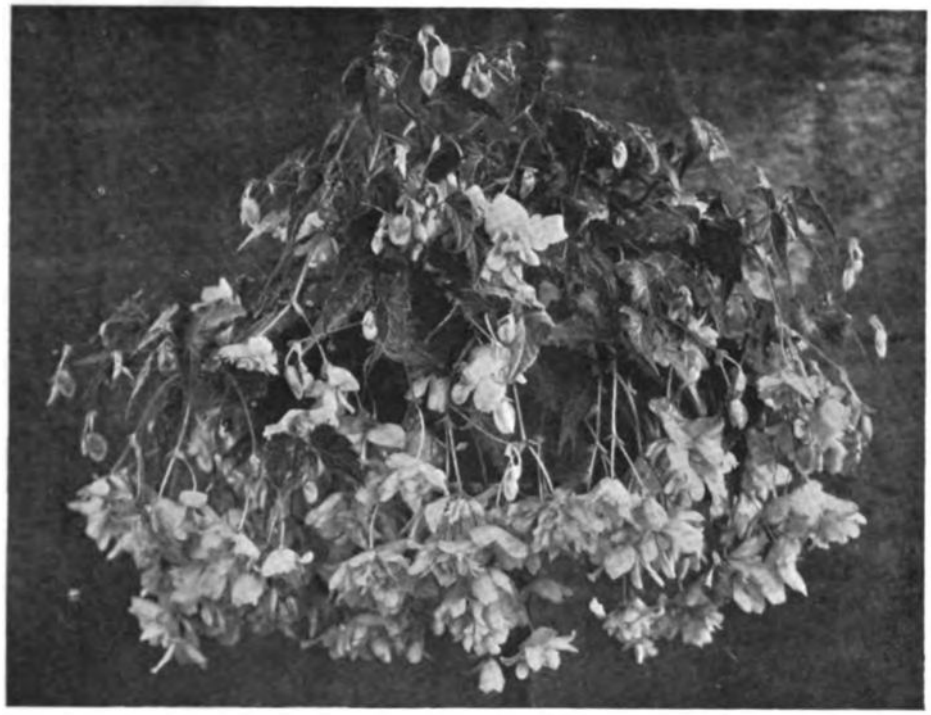
BEGONIAS FOR HANGING BASKETS

Begonias make most admirable decoration for hanging pots and baskets. They are graceful and feathery in habit, are free-flowering, with blossoms of the most delicate shades, and also supply the much needed foliage along with their flowers. They are easy to grow and reasonable in price.

THESE are the most decorative and easily grown of all the numerous types of tuberous-rooted begonias. Their remarkable freedom of flowering, the great variety of colours, their elegant and graceful habit, demand for them a place in every well directed conservatory or greenhouse. Only in very recent years have tuberous begonias been adopted for hanging baskets, and among the first used were some of the oldest double varieties, viz., Alice Manning, etc., their pendulous habits making them so very suitable for that purpose. While the range of colour among the earlier types was very limited, the present varieties embrace all colours from bright scarlet through shades of salmon and pink to the purest white.



EUNICE IS A WONDERFULLY FREE FLOWERING VARIETY WITH LIGHT PINK BLOSSOMS.

For the amateur, the most simple, straight-forward method of producing plants of these subjects, is from tubers. These should be purchased during January, February or March, and on receipt should be put into boxes about 3ins. deep, which have been prepared by having a layer of coarse leaf-mould, or some similar material, spread over the bottom of the box, to ensure good drainage, and then filled to within half an inch of the top with a good soil mixture containing two parts of well seasoned fibrous loam, one part decayed leaf-mould, a little coarse sand, and a sprinkling of soot and lime. The tubers should be put "in" the soil, being just buried and not "on" it, as is so often erroneously recommended and practised. The boxes should be placed in gentle heat of 55 to 60 degrees, if the display is required during June and July, but fine plants may be obtained by starting the tubers in March in a cold house, for late July, August and September flowering.

CULTURE.

When the plants are about 3ins. to 4ins. high, they should be potted into 3in. to 4in. pots, according to the size of the plants, using a compost similar to that recommended for the boxes, with half part of well decayed cow manure added, making sure the plants are potted firmly, without making the soil hard. In three or four weeks time these should be ready for transplanting into the baskets in which they have to flower. A basket 10ins. to 12ins. in diameter is the most useful size and should not be too deep. First of all get some good moss, that found on stones or on old tree trunks being the best, as it is more easily pulled off in slabs, and is generally a good colour. Place this inside the basket and fill it with a compost consisting of three parts fibrous loam, one part leaf-mould, half part decayed cow manure, a little soot and lime, and bone flower or bone meal. Take the plants out of the pots if they are already well rooted (this is essential), and plant either two or three in the basket, being certain, as before, that the soil is made firm. This particular point applies equally to all tuberous-rooted begonias. None of them will give of their best if the soil is loose around them. If a smaller basket is used, say from 6ins. to 8ins. in diameter, one plant will suffice, but the larger one is recommended. It will not dry out so quickly when the plants are well established, and is much more imposing.

Basket begonias commence flowering when quite young, and all flower buds must be removed for at least three to four weeks after their final move. This is a very important point to remember in growing all begonias, and particularly the basket varieties. If they are permitted to flower before the plants are established the subsequent growth becomes stunted and thin. Get good stems and foliage first and a profusion of flowers will be the inevitable result.

Many growers get excellent results by giving the plants their final move into 6in. or 7in. pots, according to the size and vigour of the plants, then placing the pot in a basket. The chief advantage of growing them this way is that the watering is more easily controlled.

TREATMENT IN THE BASKET.

Everyone has seen baskets with various kinds of plants growing in them, suspended from veranda roofs and at hotel entrances, and other similar places, in which the moss

ALICE MANNING, A YELLOW VARIETY WORTHY OF GROWING FOR ITS COLOUR ALONE.

VENUS, OF A PURE WHITE, ONE WHICH SHOULD BE IN EVERY COLLECTION.

Digitized by Google

looks like thoroughly seasoned hay and everyone will admit it does not improve the appearance of the display. If only the gardeners or men in charge would spray the moss with water from a syringe once a day, they would be astonished at the result. The moss would quickly respond and after a few days be of a pleasing green. This syringing should be done daily when begonias are used, for not only does the green moss enhance the beauty of the basket, but the begonia roots will eventually find their way to the moss, and will find nourishment instead of being scorched.

Care must be taken in watering begonias, especially when newly potted. Be sure the soil is on the dry side before adding more water. When well rooted they can be watered more freely, and a weak solution of liquid manure may be given occasionally with beneficial results.

VARIETIES TO GROW.

There are quite a number of varieties now in the market, and a selection of them, say two or three different kinds, will serve excellently for basket decoration. Among the varieties the following are good: Alice Manning, with fine yellow flowers; Coralina, a salmon pink; Eunice, of a delicate light pink with deeper flush; Lettie, a good rose pink; Meteor, a bright scarlet; Mollie, a blush white; and Venus, with flowers of a greenish white on opening and later becoming pure white. For those who find difficulty in making a selection, the best way to proceed is to purchase a collection of so many sorts. These are supplied at reasonable prices by the growers, and this method of purchase will be found a most satisfactory one.

A. G. L.

YOUR HERB BORDER

A COLLECTION of culinary herbs is one of the most useful things that a garden can contain. With the possible exception of parsley, which is often grown as an edging plant in the vegetable garden, it is really a good plan to have a special herb border. The ideal aspect for the herb border is west, for if the border faces south the situation is likely to be too hot. With a north or east aspect the herbs, with the exception of thyme and sage, will be very late in coming to perfection. Dig the ground up well and manure prior to planting. In addition it is an excellent plan to give a mulching of half-rotted manure in the late fall, not only to nourish the roots, but also to provide some protection during the winter. Here are a few useful points about the more important of the culinary herbs.

Basil.—This is a sweet-scented annual, the tops of which are used for flavouring and other purposes. To secure an early supply a few seeds should be sown in February in a pot, the little plants being hardened off and set out in April. Early in May outdoor sowings may be made. Slugs are very partial to the young plants, and to keep these away a few sifted coal ashes should be placed round the seedlings. The sort known as bush basil should be treated in the same way as the ordinary kind.

Burnet.—This is a native plant used for flavouring salads, etc. It grows best on a light soil, and may be raised from seeds sown in the open in March. Burnet is a perennial, and it must be kept in check or it may spread too far. The flowers should be removed as they appear.

Chervil.—A garden herb employed for flavouring soups and salads. The plant is raised from seeds sown at intervals during spring, summer and autumn to keep up a supply. The first sowing may be made about the middle of February. Chervil may be raised in boxes under glass during the winter if desired. Stop the plants flowering to encourage a free production of crisp leaves.

Chives.—The leaves of this plant are useful for flavouring and as a substitute for onions. Propagation is easy from seeds sown in the spring, or the plants may be increased by dividing the clumps at the same season and replanting. The leaves are fit for use as long as they remain green.

Mint.—Mint is propagated by division of the clumps in the early spring. Another easy way of growing mint is to plant offsets in the spring or cuttings with roots attached in the early summer. In dry weather mint is all the better if it is watered freely. When gathering pick off the tops of the stems to encourage the production of shoots below.

Marjoram.—This herb is usually grown as an annual, although plants will live through the winter. Marjoram may be sown in March under glass, and the seedlings are then placed outside in April. It is a good plan to lift a few plants in the autumn and put these into pots. In this way a supply of the herb in a fresh green state is maintained.

Parsley.—It is better to grow a variety

MARJORAM IS A USEFUL HERB, SEEDS MAY BE SOWN IN MARCH.

TARRAGON IS EXCELLENT FOR FLAVOURING SALADS.

with finely curled leaves, as this will do for garnishing as well as flavouring. Propagation is carried out by means of seeds sown in drills. Thin sowing is essential, and free thinning out should be adopted so that the individual plants may develop properly. Where only one sowing is made April is a good month, but to keep up a succession of young plants sowings may be made from the end of January until July. When parsley plants tend to become coarse, rather severe cutting should be practised both to prevent heading up for flower and also to encourage the development of young foliage. Although parsley is hardy, the plants which are to carry through the winter should be protected in severe weather with lights or by scattering some straw, dead fern, etc., among the specimens.

Sage.—This herb is easily propagated and grown, but it is a mistake to leave it too long in one place, as old plants have a habit of dying off during, or just after, the winter. The best way is to raise a new lot of plants from cuttings every two years, destroying the old specimens when the new ones are well established. Cuttings or slips with a heel of old wood will root freely from the end of April onwards. Another way is to pull down a few of the outer branches of an old plant and to place a little soil over the lower part so that the shoots may take root. Sage is also easily raised from seed if cuttings do not happen to be available.

Summer and Winter Savoury.—The first named is an aromatic herb used for seasoning and flavouring. Seed may be sown out of doors in April in rather shallow drills. Thin the seedlings to about 6ins. apart. Winter savoury is a hardy evergreen perennial. Propagation is carried out by cuttings and divisions in spring or by seeds.

Tarragon.—This plant is largely employed in flavouring salads and for other culinary purposes. As a perennial the best way of propagating tarragon is by means of offsets taken away in the spring with a piece of root attached. To obtain a succession of nice young growths all the summer, the shoots should be cut down at different periods to induce a succession of young stems to spring up.

Thyme.—There are two distinct forms of thyme grown, namely, the common and the lemon thyme. The first is easily grown from seeds sown in April, and it is also increased by means of divisions in the spring and cuttings in the autumn. Lemon thyme has a distinctive yellow-green foliage and a citron fragrance. Lemon thyme is somewhat less hardy than the common sort in a cold soil and it is not raised from seed. In many localities it is found to be a good plan to lift, pot and protect the best plants in the autumn, propagating from these by division in the spring. Another way is to strike a batch of cuttings in the autumn and keep these in a cold frame. In dry, warm districts lemon thyme will usually survive the average winter.

DWARF FLOWERING BULBOUS IRISES

These dainty little subjects are fast coming into flower and the rock garden enthusiast should make a note of those species which arrest his attention. They number among their ranks many choice and beautiful plants worthy of a corner in any garden, however small.

THE early-flowering bulbous irises are delightful little plants and flowering, as they do, at a time when the majority of plants are dormant, their beauty is the more arresting; possibly the most popular of these small species is I. reticulata, a lovely and well known plant. The bulbs should be planted in well drained soil in a sunny position on the rock garden or in a warm border, and under favourable conditions, they will freely increase and during February will prove a veritable joy with their deep violet and orange fragrant flowers; the bulbs may remain undisturbed for a number of years, unless they should show signs of deterioration. Failure with I. reticulata may often be attributed to a minute fungus which sometimes attacks the bulbs when left in the ground, and the presence of this disease may be recognised by the coats or tunics of the bulbs being streaked with black, and, of course, by a marked deterioration in the growth of the plant.

The variety of reticulata known as Krelagei, is dwarfer than the type, and of deeper colouring, albeit the latter varies, passing through shades of plum, purple and reddish-purple, but always of a deep tone.

I. Danfordiæ is an extremely pretty and very dwarf species with golden yellow flowers; the blooms appear almost before the leaves have speared and, like reticulata, it flowers in earliest spring and is happy on the rock garden in a sunny and well drained "pocket."

I. persica is a flower of refined beauty, the colouring bluish-green, with some orange and black markings; the very short stem bears, in March, sometimes a little earlier, one or two and sometimes three flowers; although occasionally met with in thriving condition on the rock garden, this plant is more satisfactory when cultivated in a pan for the embellishment of the cold greenhouse or the alpine house.

I. Histrio and I. histrioides are very lovely and very satisfactory little irises; the former is of blue and white coloration, the latter is similar in colouring and distinctly later in blooming, the flowers appearing usually in March, with those of Histrio almost a month earlier. There are, too, differences of habit and form, but the two plants are of equal merit and should succeed admirably in the rock garden.

I. Vartani, of slaty blue colouring, often blooms in mid-winter, so that if it is grown in the open air, it must be afforded the protection of a hand light and it is, perhaps, better treated as a subject for the cold house or frame.

I. tuberosa should appeal to all lovers of quaint flowers; the apple-green and brownish black flowers on stems about a foot high, appear in March and are undeniably pretty as well as quaint; it is an easy doer and a colony in rock garden or border is of pleasing and striking appearance. The leaves appear in the late autumn and are very similar to those of I. reticulata. This iris has been, by some botanists, separated as a distinct and monotypic genus, under the name Hermodactylus tuberosus.

I. Rosenbachiana flowers in February or March and is of outstanding beauty, the dominant colour notes being purple, yellow and white, but these are subject to considerable variation and in some forms the purple will pass into a rich crimson; this lovely plant from Bokhara is perfectly hardy, but as a protection to the flowers, which appear in early March and to the ample foliage, a sheltered nook should be selected in which to plant it, full sunlight being expedient.

A thorough ripening or "baking" of the bulbs is essential to the successful cultivation of these bulbous irises.—RALPH E. ARNOLD.

How to Pot a Plant.

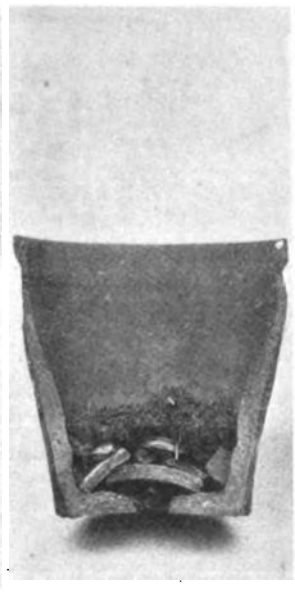
POTTING is one of the everyday garden operations, and yet it is often carried out in a very careless manner. Enormous numbers of plants come to grief just because they were not properly potted in the first instance. At all times use clean pots, and old ones should be carefully washed and then allowed to dry; it is well to soak new pots for a few hours in water, again allowing time for drying. Drainage is a matter of supreme importance when potting. A quantity of broken crocks should be at hand, and one of these which is rounded should be arched over the hole at the bottom. Then build up two or three layers of other crocks. On to these it is a very good plan to place a layer of fibre, moss or similar material. This protects the drainage and prevents the soil settling down in between the crocks and so checking the free passage of water. Now throw in some soil so that the pot is about a third full. Take a ball of the plant to be repotted and, if needful, loosen the soil a little round the roots. Set the plant in the middle and let soil fall all round the sides. A potting stick is very handy, as with this one can ram the mould in firmly. It is most important to arrange that there are no pockets or air spaces in the soil, as these holes will cause the roots to shrivel up. Fill the soil to within half an inch of the top of the pot, allowing rather more in the case of a very big pot.

Do not soak the soil immediately after repotting. If this is in a suitably moist state, as the mould always should be at potting time, it is best not to water at all for twenty-four hours. Newly potted plants should be kept in a cool shady place for a few days, otherwise they may flag badly. At no time should a plant in a pot be watered unless it is really necessary. When the soil is waterlogged much of the air is driven out and it soon becomes sour. It really does all pot plants good to become quite dry now and again, always providing they do not droop seriously. If the soil in a pot remains continuously damp it is a sign that the drainage is defective. No time should be lost in repotting the plant in a proper manner.

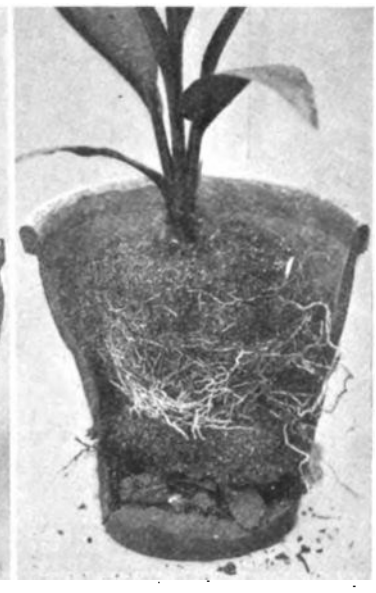
Preparing Ground for Sweet Peas and Gladioli.

BETTER results follow, especially in the case of these two kinds of flowers, if the ground is prepared for the plants—and even the seeds of the first named—and the corms, respectively, several weeks before it is required for their accommodation. Again, if the preparation is delayed until the planting time, owing to pressure of other work and other circumstances, it may not be well prepared. But now we can deal with a loose, moist soil by very deeply digging and freely manuring it, or, better still, taking out soil, forming trenches 2ft. deep and 18ins. wide, putting in the bottom a mixture of soil and rotted manure and filling up with more manure, leaf-soil, bone meal and wood ashes thoroughly mixed. The trenches should be filled, heaped about 4ins. above normal level of the ground to allow for settling down when rain comes. Having done this important work, the lover of these charming flowers can devote some time meanwhile to the young pea plants and gladioli corms, potting a few of the latter to bring them forward. Perhaps, too, the necessary support sticks can be well selected and made ready for use.

An example of bad potting. Note the air spaces in the potting soil.



Drainage is important when potting. The method of placing crocks and moss fibre.



How to repot. The soil round the roots of the plant is best loosened as shown.

Leather Jackets.

IF leather jackets are present in the soil, no time should be lost in taking steps to deal with this pest. The leather jacket is, of course, the grub of the well known daddy-long-legs fly, and in many parts of the country it causes an enormous amount of damage to seedlings and the roots of tender plants. The grub is easily recognised. Usually it is about an inch long and of a dark green or brownish colour; if washed free from soil two light-tinted lines are to be seen running down the back. These grubs are hatched from eggs in the autumn, and they are more or less dormant in the soil most of the winter, doing very little in the way of damage. When the spring comes the leather jackets develop a voracious appetite, and up to the time when they change into a dormant pupa they will cause a tremendous amount of damage.

As is the case with all pests, prevention is better than cure. Cold, ill-drained ground is a fine breeding place for leather jackets, and in such situations the plants fall easy victims. Too much farmyard manure should also be avoided, and when the grubs are known to be present the grower should concentrate on artificial fertilisers. Lime and soot are also good to work into the soil, and one or other of the well known soil fumigants will help in the work of destruction. Remedies of this nature should be applied a week or two ahead of any actual planting. Whenever digging or hoeing the ground keep a sharp look out for leather jackets and kill each one you can find.

Killing Big Weeds.

A VERY effectual way of killing the big tap-rooted weeds like dandelions, dock, etc., is on the following lines. Practically all these plants start growth quite early in the year, and as soon as the leaves are coming up the crown should be cut off quite close to the ground. Hollow out the top of the root and then press into the hole as much salt as possible. In a few days the salt will have worked its way down into all parts of the roots and the weed will never grow again. This simple plan is always effective and it saves the trouble of digging the root up.

Protecting Seeds from Mice.

MICE will often do a lot of harm to the larger kinds of seeds, such as peas and beans. The little creatures seem to take a special delight in digging these up and gnawing just as many as they can find. When the presence of mice is suspected, some preventive measure should always be taken, and one of the best of these is to roll the seeds in dry red lead before sowing. Enough of the red lead will become attached to the seeds to make them distasteful to the mice, and if a few should be eaten it is likely that the little pests will soon die. Another plan is to sprinkle a little paraffin over the seeds after sowing. This does not harm them at all, and it certainly keeps the mice away. Both these measures will discourage any birds which might wish to interfere with the seed-bed.

Seed Germination.

HOW long will it be before the seeds appear in the form of little plants? The length of time varies a good deal in the different plants, and then much depends on the weather, the state of the soil and conditions generally. In the following table the average time which elapses between sowing and germination is given. If a few extra days are allowed beyond this period and the young plants still do not appear it is usually wise to re-sow.

Beans of all kinds	7 to 9 days.
Beet	8 „ 10 „
Cabbage family	7 „ 9 „
Carrots	12 „ 15 „
Cauliflowers	7 „ 9 „
Celery	10 „ 15 „
Cucumbers	8 „ 10 „
Endive	8 „ 10 „
Lettuce	6 „ 8 „
Onion	8 „ 10 „
Pea	7 „ 8 „
Parsnip	12 „ 18 „
Radish	5 „ 6 „
Tomato	8 „ 10 „
Turnip	5 „ 7 „
Vegetable Marrow	6 „ 8

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

THE SHASTA DAISY (C. MAXIMUM).

SNOW IN SUMMER (CERASTIUM).

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

Chrysanthemum maximum (Shasta Daisy). THIS, the Shasta daisy, is very popular in gardens every where, growing as well in a town as in a country garden, and needing only the simplest of culture to gain a profusion of white flowers useful for cutting. It is quite hardy, and does best planted in a deep rich soil, growing from 2ft. to 3ft. in height. It is a favourite plant for a sunny border, and should be given room clear of other occupants. Three feet apart ought to be the guide when planting out. This is best done in March, at which time division of roots can take place. C. maximum also can be raised from seed sown out of doors in a sunny position in April or May. It commences to bloom in June and continues for many weeks.

Doronicum (Leopard's Bane). BLOOMING in early spring, and doing well in any good soil, doronicums, on account of the yellow flowers, should find a place in the amateur's garden. They are hardy perennials which increase easily by division, which may take place in October, or from seeds sown in sandy soil, in a cold frame or open ground in April. Such plants will be ready for planting out in their final quarters by October. Plants vary in height from 18ins. to 2ft. Blossoms are specially useful for cutting; the plants should, if early gathering is the object, be given a warm sheltered border, though they are not averse to a partially shaded position.

Heuchera (Alum Root). THIS is a fine plant for the border. Culture is not difficult, provided it is given a fairly rich soil, a mulch of old manure occasionally and, above all, a sunny, well drained position. A south border suits it admirably. Flowers are dainty, useful for cutting, and are borne from June to September. They are dwarf perennials with a tufted habit and are propagated by dividing the root stocks in October or March. They can also be raised from seeds, which may be sown in light soil in a cold frame in spring. Heucheras are best divided every three years.

Cerastium (Snow in Summer). THIS is a familiar plant in many gardens. C. tomentosum bears narrow silvery leaves out of which spring a prodigality of intense white blossoms during June and July. It is useful for edgings, for planting in the chinks and crevices of old walls, and for certain positions in the rock garden. Growing in any light soil, it is a plant which appears to be returning to popularity. Cerastiums are easily raised from seed sown in a cold frame in April, or propagation can be made for cuttings taken at a joint in July or August and planted on a shady border until rooted. It seldom exceeds 6ins. in height.

Gypsophila Gauze-Flower (Chalk Plant). SCARCELY any other hardy plant is more popular with those who grow flowers with a view to cutting, than the gypsophila. Its myriads of white blossoms borne on "billowy" panicles help to embellish other cut blooms. It will grow in any garden if it is given a sunny position, a deep rooting run, and soil in which lime forms a part. In planting, it is best to start with young plants, and soil should be dug out to a depth of 3ft., any deficiency of lime being made up in the form of chalk or old lime rubble. The absence of lime in the soil is one of the most frequent causes of failure with gypsophila. Flowers appear from July to September, and have a value owing to their dried character, for winter use. Once established and doing well, the clumps ought not to be disturbed, as attempts to do so nearly always result in the long fleshy roots being broken. Clumps should be planted 6ft. apart, and, as the shoots appear, they should be supported by stakes, as otherwise they are liable to snap off at the base. Propagation is best from seeds sown in pans of light sandy loam and leaf-mould in May, either in a cold frame or greenhouse, or from cuttings which appear on the shoots in July. These should be dibbled round the sides of pots of a similar compost, and wintered in a cold frame. The double form of G. paniculata, as well as the single form, should be planted, as the larger flower clusters are much more decorative.

THE LEOPARD'S BANE (DORONICUM) IS A USEFUL EARLY FLOWERING YELLOW PERENNIAL FOR THE BORDER.

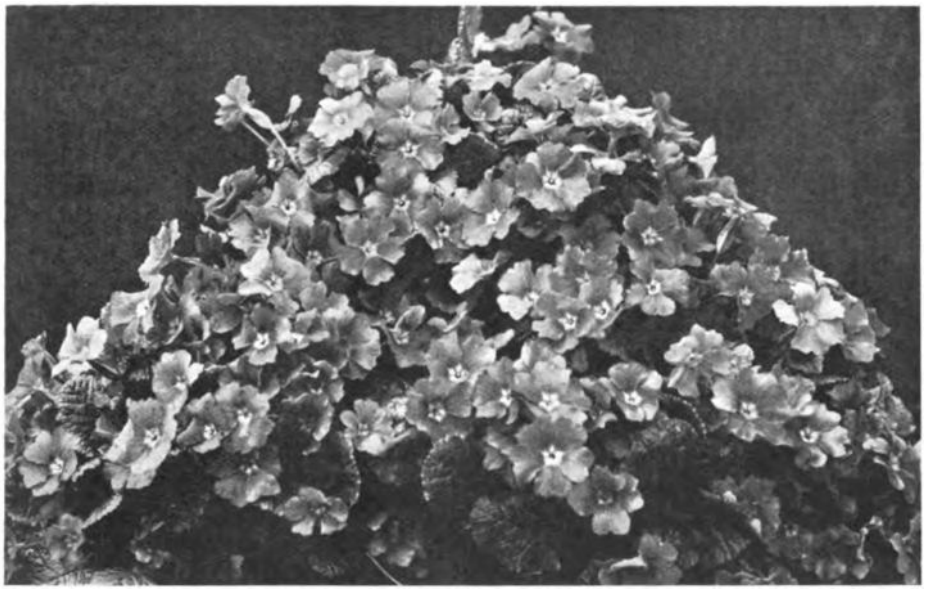
THE FLOWER GARDEN

A Free-Flowering Primula, The Jewel.

THIS beautiful and free-flowering primula is of hybrid origin, and is the result of intercrossing the well known P. Juliæ and P. vulgaris Hall's Blue. When exhibited by Mr. B. D. Webster of Newton Abbot on March 26th, 1918, before the Royal Horticultural Society, it gained an award of merit, which raises it to the class of plants of more than average merit. Like other hybrids of P. Juliæ, it possesses a robust constitution, is easily grown and exceptionally floriferous, a fact clearly displayed in the illustration. P. The Jewel is a remarkably fine hybrid with very bright ruby purple flowers with a distinct small golden yellow eye. They are about the size of P. Juliæ, but much more striking, and a mere written description of the blooms fails to do adequate justice to the charm and beauty of this plant. It is a decided acquisition for the rock garden where a moist and partially shaded position should be chosen. This class of primula requires dividing occasionally, say, every third year at least, otherwise the clumps become overcrowded with leading growths, when the flowers are smaller and less brilliant in colour. Such work is best carried out immediately after flowering, and so free growing is the plant that a good stock can be obtained in a few years.

P. The Jewel is a great improvement on P. Juliæ. It is only a few inches high, and the crinkled primrose small leaves are a dark olive green.



THE BRIGHT RUBY PURPLE BLOOMS OF PRIMULA THE JEWEL.

A Fine Winter-Flowering Shrub.

CHIMONANTHUS fragans (the winter sweet) is one of the most delightful of winter-flowering shrubs, and no garden of reasonable dimensions is complete without one or two representatives. It is sometimes referred to as Calycanthus præcox and Meratia fragrans. The flowers are produced during the winter months, the actual time being governed by the mildness or otherwise of the weather and the position. On a south wall with open weather, the yellowish green flowers will appear in December; the wood is void of any foliage and the blooms are not at all conspicuous, but the delightful fragrance is most pleasing. A few cut sprays are sufficient to scent a large room for several days, and when associated with light evergreens, a charming vase is made up, considering the period of the year. This plant may be termed quite hardy in the south and west, and even in colder districts it will succeed if treated as a wall plant with a south or west aspect. A little pruning will be needed each year, and such work is accomplished in February or directly the flowering period is over. If consideration for the future welfare of the shrub is shown when cutting flowering sprays for the dwelling house, the pruning required will be reduced to a minimum.

Plants against walls need most pruning, all useless wood and old short flowering shoots are cut out in order to encourage young growth. If well ripened next autumn these new shoots will produce a quantity of bloom in due season. Although often treated as a wall plant, it should be also planted in the open, where it will form a nice shaped shrub some 8ft. or 9ft. high. Such specimens do not require any pruning, perhaps beyond a little thinning out occasionally in February to allow plenty of sunlight to enter the centre of the shrub.

C. fragrans is increased by layers and seeds, and the former method is often practised in private gardens; any shoots near the soil being pegged down at the time of pruning, much in the same way as carnations. In addition to the type, there is a variety known as grandiflora, and this is preferred by many on account of its larger flowers, which are a purer yellow, and its stronger growth.—CHEPSTOW.

Why Not Plant Primroses Under the Garden Hedge?

I HAVE long since come to the conclusion that hardy primroses, although easy to raise, and presenting no particular difficulties of culture, are not grown very largely by the average amateur; yet there are in many gardens places where, without taking up much, if any, room needed for other plants, their presence in the springtime, when flowers abound, would be a real source of attraction. Let me press their claims upon anyone reading this note who may have in the garden a privet or quick or other hedge. We do not, as a rule, view the foot of a hedge in a very favourable light for growing anything, but even there, with a little preparation of the soil and a mulch now and again, one may have these old plants with the cheer they bring in the time of their opening leaves and blossoms. The common primrose of the woodlands and hedgerows is readily raised from seed sown in May or June. The border skirting the hedge should first be forked over, and a little old manure and leaf-soil worked in; but the best results follow individual plantings from a seed bed. Attractive as the common form is, modern hybrid primroses are doubly so, and anyone desiring a wealth of beautiful blossoms should not fail to procure a packet of seed for sowing. Dryness at the foot of a hedge is a difficulty one has to contend with, but it can be overcome very largely by improving the soil as suggested and in affording a mulch of manure to conserve humus about the roots of these welcome spring-flowering plants.—CLAREMONT.

A Perennial for Light Soils, Asclepias tuberosa.

THIS may reasonably be regarded as one of the most desirable hardy herbaceous perennials, but for some inexplicable cause it is seldom met with, even in gardens where herbaceous subjects are a speciality. It attains a height of about 2ft., and the brilliant orange flowers are borne in umbels during the months of July and August. The reason for its scarcity in some gardens may be one of soil, as this plant is never at home where the rooting medium is of a heavy clay or retentive nature. The ideal then would be found in those gardens where the soil is on the light side, such as a sandy loam and especially where it is well drained. There are numerous gardens which can supply these conditions, and it is here that this handsome border plant should be well represented. When once planted it ought not to be disturbed for several years, and when digging over the border in autumn or winter care must be taken not to injure the tubers. This I know from experience is one cause why A. tuberosa often fails to become established. Given the right soil and a light position, no difficulty will be found in the successful culture of this distinct plant. The unique colour of its flowers makes it one of the most noteworthy and conspicuous occupants in the border during the summer months and, moreover, it is of a suitable height for small gardens, while it is not liable to become too rampant. Early spring is a good time to plant.—T. W. BRISCOE.

The Newer Zinnias.

WHILE British florists have a brilliant record in the evolution of many of our popular garden flowers, we owe to American and Japanese horticulturists the newer varieties of the gorgeous zinnia. The best of all, as far as my experience goes, are the giant dahlia-flowered varieties; well grown plants in rich soil bear a wealth of extra large and beautifully tinted flowers, some of them equal in size to the average run of decorative dahlias. Most dealers stock seed, but I would remark here that a really good strain must be obtained to ensure the best result. In striking contrast to the giants are the dwarf hybrids, particularly the doubles; these produce flowers equally as large as the ordinary varieties, but they only grow to half the height, some 12ins. The miniature pompons might be regarded as "reduced dwarfs"; they only grow to 9ins., are wonderfully compact and very free. Nor must we neglect the ordinary sorts, which, in the improved or selected strains now offered, are really wonderful. It would be indivious of me to select any particular strain, for there is little to choose

Digitized by Google

in the four different sources from which we get seed. Achievement is one class by itself, the flowers being partly tubular and partly cactus-form. Hageana is another worthy of note, a single in this case; Sutton's Quilled and Fireball also deserve a word. In closing I advocate a first sowing made at the end of February, but main sowings a fortnight or ten days later; the seedlings must be kept near the glass to encourage sturdiness and branching. Transferred to the frame in May, they can be planted out the first week in June. They also require a rich soil and there is no better time than the present, when ordering seed, to set about the usual trenching and heavy manuring so essential to success. I might remark, too, that zinnias make good pot plants for greenhouse decoration in summer and autumn, March sowings may be made for this purpose. —LANARKSHIRE.

A Delightful Spring Association.

Rhododendron præcox and Erica carnea.

I BELIEVE Rh. præcox was raised by the late Mr. Isaac Davis of Ormskirk from two early-flowering rhododendrons, *viz.*, Rh. ciliatum and Rh. dahuricum, and the result is a charming early-flowering plant, suitable alike for beds and the cool greenhouse. When grown in pots for the latter it can be had in bloom early in the year without any forcing in the ordinary sense of the term. This plant has been raised by others, and in consequence there is a certain amount of variation in the colour of the flowers even if not in the actual time of blooming. The variety quoted in this note is Early Gem, a Veitchian introduction, and this will be in flower towards the end of January given open mild weather, but if cold they will be later—the photograph was taken on February 21st, 1926. The flowers are a bright rosy purple, and if the weather proves congenial a bed of this dwarf rhododendron is indeed a lovely sight. The plant is quite hardy, but it should be understood that occasionally the expanded blooms and buds are ruined by frosts or wind and rain. Nevertheless, it is worthy of a place in gardens on account of its early-flowering qualities, especially if it can be afforded a sheltered position. The illustration shows a bed of Rh. Early Gem and Erica carnea at Castleford, Chepstow, and the twain make a pleasing combination. Both are in flower at the same time, and the rhododendrons rising above the erica take away any idea of stiffness. The rhododendron rarely requires any pruning, but the erica should be trimmed over with a pair of shears directly the flowering period is over. To be successful with these plants it will be advisable to prepare the root-run, unless it is free from lime. Otherwise leaf-mould and peat should be freely added.

A FINE BED OF RHODODENDRON PRÆCOX AND WINTER-FLOWERING HEATHS.
Such an association will give colour to the garden during the late winter months.

New beds or borders should be prepared and planted during the winter months or immediately after the flowering period.—T. W. BRISCOE.

Sidalceas for the Garden.

THE grower or gardener who wishes to keep up with the times and also to possess representatives of a charming family of plants, must include several of the newer sidalceas. For many years we only knew S. Listeri, a poor thing in spite of glowing descriptions in catalogues, and the white S. candida. Now, however, Mr. H. Hemsley of Crawley has produced a wonderful series, by hybridisation and rigid selection. A few of the named varieties include Rose Queen, Rosy Gem and Sussex Beauty, the latter being a charming plant with large open pink flowers. Rosy Gem is bright rose and obtained an award of merit from the Royal Horticultural Society. Unnamed seedlings can be obtained from several firms on very reasonable terms, and these furnish a wonderful range of colour, through various shades of pink, terra cotta, ruby and brick red. All the flowers are furnished with a beautiful satiny sheen and the plants as a whole are most graceful. They attain a height of 2ft. or 3ft., the light spikes of bloom being admirably suited for cuttings, in addition to making a fine display in the border. Owing to the strong stems, they need little or no staking, but in exposed positions it is advisable to use a few twigs as supports.

Sidalceas possess all the attributes of good garden plants, they grow freely, are perennial and can be readily increased by division in the early spring or just before growth begins. They commence to push up their spikes about May, and continue in bloom from July till September. While the named kinds could very well be grouped in the herbaceous border, beds of seedlings or unnamed varieties are sure to be appreciated, especially where a fine display is needed in August. Providing the site is away from the permanent shade of large trees, the sidalceas will be a success, they will revel in an ordinary border and, judging from last summer, they do not object to a dry time, in fact they were fresh and pert when other plants near by were drooping. It is a gardener's plant *par excellence*, not only on account of its easy culture and floriferousness, but also for its fertility, seeds being produced in quantity. Although saving one's own seed from selected plants is an interesting and often profitable pastime, it is advisable to purchase seeds, which can be obtained from most seed firms; but a good strain should be chosen, as finer plants and better colours are then obtained.

Seeds may be sown in February or early in September, and if raised in a warm greenhouse, some of the plants will bloom a little this year. They may also be sown outside in March.—W. B.

THE FRUIT AND KITCHEN GARDEN

Do Not Forget to Plant Shallots.

THE inclusion of this vegetable among kitchen garden crops is usually appreciated by those who have charge of the kitchen, and they are certainly exceedingly useful, not only for pickling, but also for flavouring soups, stews, etc. An additional merit lies in their long keeping qualities, which render them available for use all the year round.

Although a native of Palestine, the shallot is quite hardy and it is the rule in certain localities to "plant on the shortest day and lift the crop on the longest day." This early planting is not to be recommended, however, except in small quantities, for the production of a few early bulbs.

The shallot thrives best in a warm, light, rich soil, that has been liberally manured for the previous crop. On recently manured or badly drained soil it is liable to become attacked by a maggot or a mould.

The principal planting should be made during the first open weather in which the soil is in a crumbly, friable condition in January or February. Later planting does not favour good results.

A distance of 6ins. will be sufficient between the bulbs or "cloves," as they are often called, and 1ft. may be allowed between the rows. An alternative plan is to use them as an edging for beds of other vegetables. Do not bury the cloves deeply, but merely press them into the soil about one half their depth. It is usual to scrape away the soil from around the bulbs when they have become well rooted later in the season, thus leaving the bulbs above the surface of the ground and allowing them to receive the full benefit of the sun.

During the growing period, hoeing to suppress the growth of weeds is the only necessary operation. About July or August, when the leaves begin to turn yellow and wither, the tufts of bulbs may be pulled up, left on the ground for a few days to become thoroughly dry, and then divided and stored in a dry, airy, frostproof room. A proportion of sound, well-ripened bulbs, should be selected for planting the following year.—T. H. EVERETT.

Giving Assistance to Bean Seedlings.

THE most critical time in the growth of dwarf and runner beans is the period during which the shoots are pushing through the soil as the seed germinates, when they are subject to the attacks of slugs in particular and may find difficulty in getting through the crust of hard soil where such exists.

The best procedure is to apply lime. It should be strewn thickly in a ring around the shoot—about an inch away from the latter. This is effectual in keeping the slugs at bay, and it should be renewed occasionally until the bean is at least 3ins. above the ground, for the smallest opening in the ring of lime will be taken advantage of by slugs. Soot and salt have the same effect.

Meanwhile, every effort should be made to assist the bean shoots in their struggle to get clear of the soil. Should the ground have become hard and caked by heavy rains or drying winds, it is best to stir the soil around the shoots with a pointed stick, so as to keep it loose around the plants.—A. Y.

Mint.

MINT, in some soils, is almost as easy to grow as couch grass. In others, it is a difficult plant to manage. There is always a demand for fresh mint in the household and, as it is not difficult to force an early supply where there is a glass structure quite warm enough to excite the roots, a start should be made now. Begin at one end of the bed of mint and lift every piece of root found there. Then pick out the strongest and bury the weakest in soil again, but only temporarily. Procure two or three boxes about 18ins. long and 14ins. wide, 5ins. deep; place a thin layer of old potting soil in the bottom of each, then the mint roots, lengthwise, covering them 2ins. deep with the same kind of compost; make it firm while it is rather dry, then thoroughly saturate it all with clear water, applied through a rosed watering can. The boxes may be placed under the stage near the hot-water pipes till the new shoots begin to grow; afterwards, of course, full exposure to the light is essential, as the leaves must be quite green. The small roots, heeled-in, should be planted in a moist soil, if such is available in the garden, or in a position partly shaded from the sun's rays. Mint thrives in a moist rooting medium and is often very disappointing in a shallow, dry or sandy soil on high ground. Watering it in such positions is practically useless, as the leaves soon become covered with a rust on the undersides.—G. G.

How to Get an Early Crop of Peas.

IN many soils it is impossible to sow peas with safety in the early weeks of the year, while in some districts the weather is far too cold to permit of this being done successfully; but there is a method by which both soil and climate can be circumvented and the early crop of peas secured.

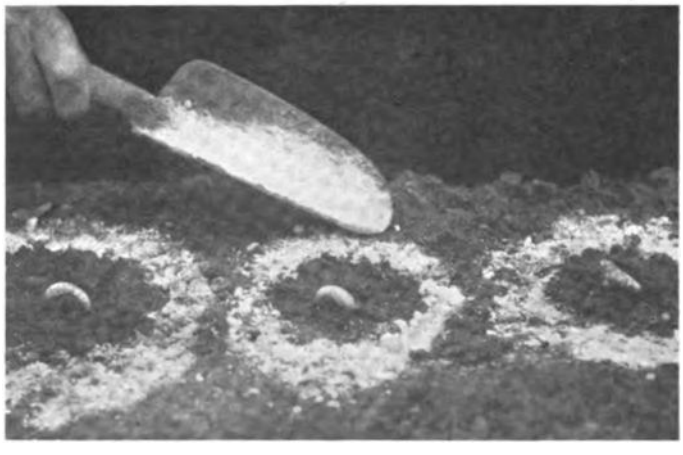
The means of bringing this about is the possession of a quantity of glass, of any size and shape. Those who can get old photographic plates will find them a boon; builders will be willing to supply odd pieces of glass for a small sum, and those who can afford a quantity of glass cut to long or short lengths of about 6ins. wide will find them useful each year for many similar purposes. The pieces of glass may either be tilted against each other to form an apex shelter over the seeds, or can be pushed into the ground on each side of the row and another piece laid on top. Whichever way may be adopted, a snug little glasshouse

A SURE METHOD OF OBTAINING AN EARLY CROP OF PEAS.

is erected over seeds and seedlings which induces quick germination and protection from birds, mice and insects.

The best way to sow the seeds is to make a deep drill and half fill it with a fine sandy compost. Sow the seeds on this, and then place the glass along either side of the row. Cover the seeds with more of the good soil, press it down gently and then place the pieces of glass over, or gently press the top edges towards the centre of the row. The edges of the glass need not meet—sufficient protection and warmth will be afforded even if no glass is placed over the seeds, the side pieces doing this work well. Of course, the top covering will form an excellent protection against the attacks of birds and mice.

After the pea plants have attained a "safe" size, the glass should be removed and it will be found equally useful in the sowing of other crops.—H. D.



TO CIRCUMVENT SLUGS, PLACE A RING OF LIME, OR SOOT AND SALT ROUND EACH YOUNG SHOOT AS IT APPEARS.

Potash for Tomatoes.

IN animals and plants it is gradually being recognised that certain diseases are due wholly to, or owe their virulence mostly to, a deficiency in diet. In the raising of tomatoes this is probably at least partly true; at any rate, we ourselves have clearly proved that when potash is overlooked in the compost then the plants are not so good as they might otherwise be. Again, potash in sufficiency has much bearing on the quality of the produce; "potash for quality," indeed, ought to be a slogan among growers. Thirdly, we are certain that a balanced food ration is conducive to that stubby, uniform, hardy growth which betokens fruitfulness, and that excessive use of phosphates and nitrogenous matter may defeat its own end. Wood ashes form the best source of potash, but few there are who can supply the large quantity needed; where it is plentiful a trowelful per plant is a fair supply, scattered over the soil and then forked lightly in. So soluble is this potash, however, that it pays to apply the above

Digitized by Google

quantity in two or three dressings before planting, before fruiting and in mid-season. Sulphate of potash is the best artificial to apply before planting; in a greenhouse border I should apply 1½oz. per square yard up to 2oz., in two dressings, one before planting and one when the first fruits are forming. For application in liquid form during growth, a very effective way of using potash, saltpetre is slightly better than sulphate, ½oz. per gallon of water is the usual amount and this for four plants weekly, during the time growth is active and the plants in full bearing. Proprietary artificial manures usually contain the correct proportion of potash.—LANARKSHIRE.

POTATOES FOR THE AMATEUR

THE selection of seed potatoes suitable for planting in the amateur's garden is not an easy task when we consider the many hundreds of varieties from which we can choose. Many, it must be admitted, are old and would be out of date when considered along with the newer varieties that have been recently introduced. Champion, Buchan Beauty and Paterson's Victoria are

A GOOD CROP OF KERR'S PINK, A FINE VARIETY FOR THE AMATEUR.

now not often to be seen in gardens; however, they served their day, and it might be of interest to note that those varieties have been used as parents for many of our recent introductions.

First Early Varieties.

As a first early variety, one cannot do better than plant a few rows of *Di Vernon* (*Immune*), for, if sprouted and planted out early in March on a south border, they can be lifted in about ten weeks' time. The habit is dwarf, the tubers are flat kidney shaped with purple markings around the eyes. Quality excellent, and one which should be grown by all who wish to grow a really good first early.

May Queen (*Non-immune*) is an early of rapid growth, haulm dwarf. Tubers white kidney with very shallow eyes and smooth skin. A variety well adapted for growing in frames and early borders.

Finally, among earlies of merit, we have *Duke of York* (*Non-immune*), thick kidney shaped, yellow-fleshed tuber, too well known to need description here. Many stocks, unfortunately, are poor, and care should be taken to obtain a healthy strain if the best results are to be expected.

Second Earlies.

Snowdrop (*Witch-hill*) *Immune* should follow the first earlies. Kidney in shape, white flesh and skin, very dry, and of fine flavour. It is certainly an old variety and one which, we might say, has a history, for it was the first potato which was discovered to resist wart disease. The plants are tall; flower white and fairly profuse. Many times we find it classified as an early, but, to my mind it is an early second early.

If one wishes to grow something new, *Clovullin* (*Immune*) should be given a trial. Raised by a famous grape-grower—Mr. McInnes, Glamis. A variety that will fill a gap among second earlies, and I would thus recommend it for garden culture. The tubers are white with shallow eyes. The growth is robust, with large flat pale green leaves of spreading habit.

Arran Comrade (*Immune*) may not now be called a new variety, still we cannot be without this potato, it is so beautiful and even in shape and pleasing to the eye. The tubers are round, white with shallow eyes, and of good quality. A potato seen on every exhibition table. A heavy cropper; as many as thirty tubers may be produced at one stem. Rather susceptible to ordinary blight and should be sprayed and lifted as soon as ripe.

Great Scot (*Immune*) is another popular variety, and when sprouted before planting matures fairly early. The tubers are round, skin lemon in colour but with white flesh. A heavy soil suits this potato. The growth is very upright and vigorous. It should be eaten before Christmas, as it is liable to turn black in cooking if kept too long.

Maincrop Varieties.

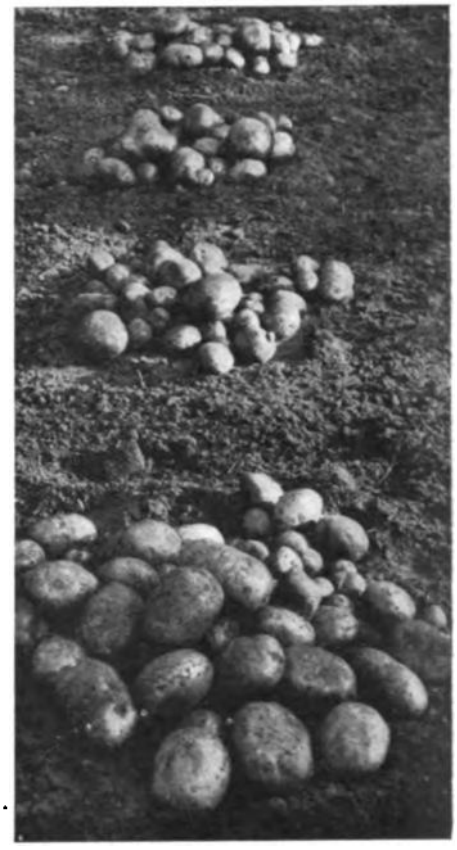
Taking maincrop potatoes, *Incomer* (*Immune*) is something new, for, I believe, it is put on the market for the first time this year. A tall, upright grower, strong, robust habit with white flowers. Broad oval white tubers with shallow eyes. I had the pleasure of seeing this potato growing for two years, and it was certainly very promising

Another maincrop potato also introduced this year is *Claymore* (*Immune*). It stands out pre-eminent as a cropper. The tubers being large pebble-shaped with shallow eyes. Growth strong, with dark green foliage and a profusion of white flowers. For garden culture this variety is certainly a great acquisition. Quality is said to be excellent. Very resistant to blight.

Two other immune varieties suitable for garden culture are *Kerr's Pink* and *Golden Wonder*. Kerr's Pink is a Banffshire variety, too well known to dwell upon its merits here, both for quality and quantity. It is round, pink, deep eyes certainly but of lovely white flesh, and cooks like balls of flour. Unfortunately, this variety is frequently substituted, and care should be taken to secure the proper stock. Golden Wonder produces shapely kidney tubers, not a particularly heavy cropper unless heavily manured. Does best in a wet season. Snails and slugs are very partial to this variety.

Finally, we have *Bishop* (*Immune*), one of the finest exhibition potatoes grown. The tubers are kidneys with very shallow eyes. Skin white, flesh slightly lemon. The flowers are rose purple and very profuse. Quality splendid.

The above selection does not by any means exhaust the number of good varieties. A perusal of catalogues of the firms dealing in seed potatoes will give abundant evidence that there are other sorts which might be considered as good as those already mentioned. Harbinger and Ninetyfold among earlies;



ARRAN COMRADE, A HEAVY CROPPER AND OF GOOD QUALITY.

Catriona, Sharpe's Express, British Queen and Stirling Castle for second earlies, and maincrops' Ben Lomond, Ben Cruachan, Celt, Tinwald Perfection, Norna, etc., have all established reputations.

Preparation of the Ground.

As the potato is a sun-loving plant and appreciates a well aerated soil, no care and trouble should be spared in providing these important essentials. It, therefore, pays to have the soil well broken up and left rough during winter. Decayed farmyard manure should be mixed with the top spit, and also plenty of partly decayed leaves incorporated near the surface. This, to a certain extent, will make the soil more friable and lessen the attack of corky scab.

Planting

March and April are the two planting months. First and second earlies which had been sprouted should be planted out about the end of March, and the maincrops during the month of April.

Digitized by Google

Drills should run north and south to obtain the maximum sunlight for the plants. The distance between the drills will, to a certain extent, depend upon the growth of the variety. As a rule, first early and dwarf varieties should have 24ins. between the drills and 12ins. between the sets; while second early and maincrops should have 27ins. to 30ins. by 12ins. to 15ins. Plant so that the tubers are placed 4ins. below the surface and kidney varieties set on their sides, this being the natural way in which the potato is produced on the plant.

Manuring.

It has been proved beyond doubt that it is more economical to give farmyard manure during winter and a dressing of artificials at planting time. The following mixture has proved effective on medium soils: 1½lb. sulphate of ammonia, 3lb. superphosphate, 1lb. steamed bone-meal and 1½lb. sulphate of potash, mixed together and applied on the top of the drills and raked in after the tubers are planted and covered in. The above quantity should be sufficient to manure a drill 10oft. long. Artificial manure applied in the drills and the sets planted on the top of the manure is a practice that cannot be too strongly condemned. Clean-skinned, healthy tubers can only be produced when the manure reaches the plant in a soluble state.

Treatment after Planting.

When the plants appear the ground should be hoed over and the area between the rows loosened up with a digging fork. Earthing up should take place when the haulm is 6ins. to 8ins. high. Endeavour to build up broad, flat-topped drills.—GEO. STUART.

WHAT OUR READERS SAY

POTENTILLA NITIDA.

SIR,—It may interest Mr. Fox to know that I succeeded in getting this beautiful plant to flower by putting it into scree mixture, including old mortar and planting it in full sun. I cover it with a bit of glass in wet weather. I also had failed in ordinary garden soil.—C. G. FIELD-MARCHAM, *Tunbridge Wells.*

GENTIANA SINO-ORNATA.

SIR,—Do the flowers of this gentian vary in colour according to the nature of the soil in which the plant is grown? I am inclined to think they do, for the following reason: My plants, from two sources, have flowers of an intensely brilliant blue, like those of G. acaulis at its best, when grown in the garden here in a soil largely composed of leaf-mould; but pieces given to a friend and grown in what appeared to be suitable conditions, developed flowers of a dull slaty blue, giving one the idea that there was a larger proportion of red in the colour, neutralising the blue. I have also noticed in other gardens flowers of this dull blue and have put it down to a poor strain, but perhaps I was wrong in this and it was something in the soil that was responsible. I wonder if any of your other readers have had a similar experience with this wonderful autumn-blooming rock plant.—R. B. C., *Northumberland.*

PLANTS WHICH CAN BE GROWN IN A DISUSED QUARRY.

SIR,—"J. D. B." asks in THE GARDEN for information as to what plants may be grown in a disused stone quarry, and the names of certain plants have been furnished. In addition, I would like to call his attention to one very partial to such an environment. It is the dipsacus, or teazel. Some years ago, when in an old quarry, I came across quite a number of plants carrying many heads, and brought a few home, shaking out the seeds and sowing them in the open ground in the following April, to be rewarded by plants which produced the peculiar thistle-like heads the next year. They are mostly of biennial growth, quite hardy and will grow in any rough soil and between fissures of stones, so long as they can have a little soil. Two or three seeds should be sown together and one plant only left, as they grow anything up to 6ft. in height, and should therefore be planted where they will not overshadow other things. About July the heads, of a blue-green, are very pleasing, but as autumn approaches, they turn brown and are sometimes used in connection with "everlasting blossoms." Once planted in a garden, it is scarcely needful to sow again, as they perpetuate themselves from the seeds which drop.—W. F.

[If any part of this disused quarry has soil which is chalky in nature, we should like to refer our correspondent to an article entitled "Notes from a Chalk Garden," which appeared in our issue of July 5th, 1924, page 467, where he will find a useful list of plants growing in one of the finest chalk quarry gardens in the country.—ED.]

DO PLANTS PREFER COMPANY?

SIR,—In a note from "G. G." on page 26 of THE GARDEN in reference to the raising of leeks, he points out that it is better to transplant young plants into boxes, rather than to do so in singly small pots. I can corroborate this statement from a long experience with this very useful vegetable. On one occasion, being desirous of having extra good plants, I went to the trouble of potting a number, only to find that they did not make the same progress as plants out of the same seed box did, which were transplanted in boxes made up of the same compost. As pointed out by the writer of the paragraph, it is important that young leeks should be given at least 9ins. of soil when transferred to boxes, so that when the time comes for planting them out of doors, they will be well equipped with roots. I do not know whether the idea is far-fetched, but I have noticed other seedlings—tomatoes, for example—come on much quicker when companied side by side in a pan or box than when isolated in a pot to themselves. An old grower of leeks held tenaciously to the opinion that "leeks grow faster and do better when in a box together." What reason he had for saying so, beyond his own experience, I do not know, but I have certainly noticed that when placed in a pot to themselves, they do not turn out with roots like those in a moderately deep box.—F. W.

CARE OF SEED POTATOES.

SIR,—The decay of seed potatoes in the store often causes serious loss to the amateur grower. This loss may to a certain extent be checked if timely action is taken to look over all seed tubers occasionally and have the diseased ones removed and burned. This decay and loss in the store may be caused by several diseases. One of the worst the grower has to contend with is blight. Early and second early varieties being most susceptible and care must be taken to see that dried and shrivelled tubers are removed forthwith, otherwise healthy tubers would be affected and a whole stock ruined before the planting season comes round. Blight generally, although not always, cause infested tubers to shrivel and dry up, but sometimes the disease appears as a wet rot. This wet rot is due to the presence of a saprophitic fungus which attacks the blighted tubers and spreads to healthy tubers, gaining an entrance through bruised and damaged skins or it may be by the watery and pulpy material coming in contact with the skin and passing through the lenticels. Another serious cause of decay in the store is dry rot. It differs from ordinary blight in that the tuber rots to the centre, while blight may only penetrate underneath the skin, leaving the centre quite firm. The early stages of dry rot cause the tubers to become wrinkled with sunken patches on the skin. Later on white powdery pustules appear to burst through the skin, the tubers feel light, are usually brown and hollow in the centre and the skin hard.

Preventive measures should at once be taken to see that all damaged and diseased tubers are removed and burned at once and the healthy sets placed on trays to sprout and exposed to light in a cool, frost-proof shed. Potatoes should not be left to sprout in the dark, otherwise long, spindly shoots would ensue. There is also the question of "roguing" seed potatoes in the store. This work should be carried out when the sprouts start to grow. Once the variety can be distinguished by the colour of the sprout all those showing any suspicion of not being true to type should also be removed, thus keeping each variety as pure and healthy as possible.—G. S.

THE CULTIVATION OF LILIUM LONGIFLORUM.

SIR,—A correspondent in Guernsey, after announcing his intention of concentrating on the cultivation of Lilium longiflorum giganteum recently, enquired as to the possibility of growing these lilies in the open ground, and further, whether he could obtain a show of bloom in September-October. The well known mildness of the Guernsey climate should present no difficulties to outdoor cultivation, although it is possible that protection both against wind and rain might be, if not essential, at least desirable. (A rain-swept blossom suffers from the pollen being washed upon, and staining, the petals.)

As for obtaining blooms round about a given date: as a broad general rule, unforced bulbs come into flower about three months after planting—forced ones about two months. The trouble arises when the amateur desires to obtain lily bulbs, say in June and July, that are likely to flower. The ordinary man has not the facilities for cold storage and retardation enjoyed by the professional grower and, should he purchase from the average dealer, he will possibly obtain unsold and deteriorated stock, cheap in price—and performance.

The earliest longiflorum bulbs to come on the market are of Japanese origin. These begin to arrive in January, and for some eight to ten weeks gigantic consignments of them and other Japanese lilies reach our ports almost daily. The condition of the bulbs varies greatly: some arrive plump and firm, others the reverse; and, in any case, the wasting of the bulb, removal of damaged scales, a light dusting with flowers of sulphur, to say nothing of a preliminary "conditioning" of the bulb before planting, are desirable. This "conditioning" enables the cultivator to discover, discard and destroy such bulbs as show obvious signs of disease.

Soon after the supply of Japanese bulbs begins to tail off, further stocks start arriving from Bermuda—which, not so many years

Digitized by Google

ago, used to enjoy a trade almost as extensive as that of the Japanese.

Last on the list of arrivals come the New Zealanders, which arrive in May - June. So far, the growth of bulbs in New Zealand for export is in its infancy. Some enterprising pioneers have made an eminently courageous and successful start. The consignments of bulbs sent by them to this country being well grown to standard and thoroughly healthy. These latter will provide the late flowers desired by your correspondent.

Brief allusion has been made to professional growers of lilies for the cut-flower market. These gentlemen ensure a constant supply of bulbs by purchasing large stocks, keeping them in cold storage at a temperature just above 32° Fahr., and withdrawing the cases as required. The bulbs are forced, flowered, cut, and the spent bulbs thrown away. It is also worth noting that the market growers take full advantage of each crop as it arrives. It stands to reason that to pay rent for a case of lilies in cold store, when you can get a similar case on the market for which no rent is necessary, is bad business; so that the cold-stored bulbs are only really used when fresh bulbs are not available.

The Japanese bulbs are offered in nearly every January bulb and seed list.

The addresses of retailers of Bermudan bulbs could be obtained from the Secretary to the West Indian Committee, Trinity Square, London.

The New Zealand bulbs from Amos Perry, Hardy Plant Farm, Enfield, Middlesex; and, if your correspondent obtained any from the latter source, why not try L. sulphureum? A lily of conspicuous beauty, late flowering, that in England requires, save in favoured spots, the adventitious protection of a greenhouse in October, but which in Guernsey should, by rights, thrive exceedingly.—C. J.

PETROL AS A REMEDY FOR AMERICAN BLIGHT.

SIR,—In your issue, December 8th, 1926, H. G. Longford, in criticising my hints on American blight, says that petrol is of little use in the winter months, as the pest is safely protected *within* the bark. Does he mean that it burrows into the bark? If he does, I think he is greatly mistaken. It is stowed away tightly in the crevices and folds of the wound in which it has been working, and if petrol is tried as a remedy it will do its work just as effectually as methylated spirits at a *portion of the cost*, and, as I said, is *procurable in every village in the kingdom*. I have never seen a tree so badly infected as to have it on the new growth and if I had one such tree I should certainly grub it up, for my own as well as my neighbours' sake. Such a tree would infect a whole neighbourhood by flying aphides. Unfortunately, there is no cheap means of killing it on the roots; flooding for forty-eight hours will kill it where it can be done; or fumigating with bisulphide of carbon, which is too expensive. Prevention is always better than cure, and can be done by using blight-proof stock —Northern Spy for preference.—R. C.

AN "ADCO" MUSHROOM BED.

SIR,—With reference to the letter from your correspondent "C. J." in your issue of January 1st on the growing of mushrooms on an "Adco" bed, we send you herewith an extract from a letter, dated October 18th, 1926, from Mr. W. Auton, our horticultural adviser. Mr. Auton's remarks on this subject may be of interest to your readers. "*Re* mushrooms, I regret that I cannot report good results. I have made and spawned several beds this summer, but only one of them has produced mushrooms and that a light crop after an abnormally long time. This was with a mixture of grass cuttings and leaf in about equal proportion. 'Adco' Accelerator being used in the usual quantity. The heap was turned every other day for fourteen days, then made into a compact bed and spawned immediately. I am handicapped in that I have no mushroom house, and the fact that I have produced mushrooms under more or less improvised structures gives some satisfaction, as the results in a mushroom house, where moisture and temperature are more equable, would probably be much better. I consider it is quite right to tell enquirers that the mixture as given above can be used as a substitute for horse-manure in making a mushroom bed, and those who make their beds in a mushroom house will probably get much better results than I have got."—MESSRS. ADCO, LIMITED.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Damping-Off of Early Tomatoes.

Many gardeners complain of damping in tomatoes, especially in December and January. To avoid this, smash up a few pieces of brick and pass through a ¼in. sieve, using the rough for crocks and the fine mixed with the soil. The first pricking off should be four around the edge of a small 60-size pot until they have made a little more root; then after a week or two place singly in large 60's, press firmly round the edge, leaving the soil around the stem a little higher so that when water is given it runs around the edge without touching the stem. In both cases use lumpy soil and scatter a little brick dust on the surface. From 100 seedlings pricked off the last week in November only three have damped.—F. D.

Sweet Peas in Seakale Pots.

Lovers of sweet peas whose gardens are very tiny are advised to try growing their peas in seakale pots or tubs. These pots can be stood on the lawn or path or front door steps, thus saving space in the flower-beds. The pots should be filled with the grower's pet compost up to about 3ins. or 4ins. from the top. Sheets of glass can then be used to protect the young plants, thus making autumn or very early spring sowing quite safe. I have followed this plan for several years and have had excellent results. Plants grown this way bloom three or four weeks ahead of those sown in the open ground in March or April, so that those who can afford space in their beds also will find this plan useful for prolonging the season.—K. B.

Remedy for Cineraria Leaves Curling.

This is to erect a tray 3ins. or 4ins. below the staging on which the pots rest and of the same area as the staging. Scatter thickly on this tray moss, ashes or gravel (preferably moss), about 2ins. thick. Keep this moist, and it will afford the best conditions for cinerarias.

I suggest, as an alternative to this, if it is too expensive: to lay slates on the staging and put the pots thereon. This latter will prevent too much hot air rising directly to the plants and thus keep the plants cool.

Cyclamens do well on such a staging also, and any other plants which cannot do with a dry atmosphere.—H. M. G.

A Cheap Frame.

Bricks being costly, I built three frames for the cost of a bag of cement. This I mixed dry with 4 bags of clinker broken up the size of cob nuts. I then made some rough shutters the size of a frame, keeping them 6ins. apart to form the wall. The cement and clinkers were well wetted and mixed and the space between the shutters filled in and left for forty-eight hours to set, when the shutters were removed a solid wall was the result, which, after eight years' use, is as good as ever, and no repairs are ever needed. —H. M. B.

Sprouting Early Potatoes.

Everyone likes to have new potatoes as early as possible, and I generally dig new potatoes in my district before any of my neighbours. Getting the seed fairly early, I place each tuber carefully into a shallow box which has an inch or so of leaf-mould at the bottom, and put them under the greenhouse shelf, keeping them just moist. By March they have strong shoots, and have also started root action into the leaf-mould. Lifted carefully out and planted into the potato plot, they never have a check, and are soon above ground going strong. This is my secret of getting the earliest potatoes. —W. T. S.

The Care of Cyclamen.

Great care is needed in watering cyclamen. A good plan is to plunge the pots in boxes of sand and when water is needed apply to sand. By this means danger of rotting the corms or falling leaves is obviated.—T. H. H.

Propagating late Chrysanthemums

The late-flowering indoor chrysanthemums should be propagated early in the New Year. Some varieties are what gardeners call shy and do not throw up cuttings very readily. In order to make sure of cuttings, knock the old stool from its large pot and repot in a small one (say 6in.). Use good potting compost, when more and suitable cuttings will be thrown up.—T. H. H.

Practical Method to Produce Early Peas and Broad Beans.

Mix 3 parts loam and 1 part leaf-mould with a little sand. Sift through a fine sieve and place the soil in the greenhouse for a few days before using, to warm and dry. Secure some plant pots (large "60's"), put in a few leaves, then three-parts fill them with soil. Place five peas in a pot, broad beans two in a pot. Cover with fine soil, leaving ½in. from rim of pot for watering, then place in greenhouse. One watering is sufficient until the seeds have germinated. When 2ins. high place in a cold frame with plenty of air day and night. When planting outside, open a trench with a spade 3ins. deep. Each pot will form a clump if placed 10ins. apart in rows. I have found Peas Little Marvel and Pioneer, and Broad Bean Mazagan, the best for early use. Recommended by a firm of market gardeners and tried for years without failure.—B. R.

GREENHOUSE NOTES

Some Hints on Forcing.

THE following are a few general hints on the forcing of vegetables and fruits under glass or in darkness at this season of the year. I will first refer to fruits, mainly grapes, peaches and nectarines. It was a general practice, forty years ago, to place fermenting material in a heap in the vinery, near mid-winter in order to supplement the heat from brick flues and hot-water pipes. In the case of brick flues, the dry heat from them was counteracted by the moist heat arising from the hot-bed on the vine border. The warmth also affected the roots of the vines, and the latter began to grow very kindly.

In these days, when fuel is scarce and dear, amateurs may, with advantage, make up hot-beds in their vineries to assist the growth of the vines. Bulbs in pots and boxes, spiræas, deutzias, azaleas and similar kinds of plants in pots may be placed in the vinery and, at first, near the manure heap, and their growths will be hastened. Directly the vine buds break, remove the heap of manure from the house. Rhubarb and seakale may be forced under stages, being kept in darkness by fixing mats in front of the stage. Hot-beds, under garden frames, do at first emit rank gases, and these would be harmful to tender growths if confined in a closed frame. There will not be any danger to plant life if a small opening is left at the top of the frame, as these gases soon escape.—HANTS.

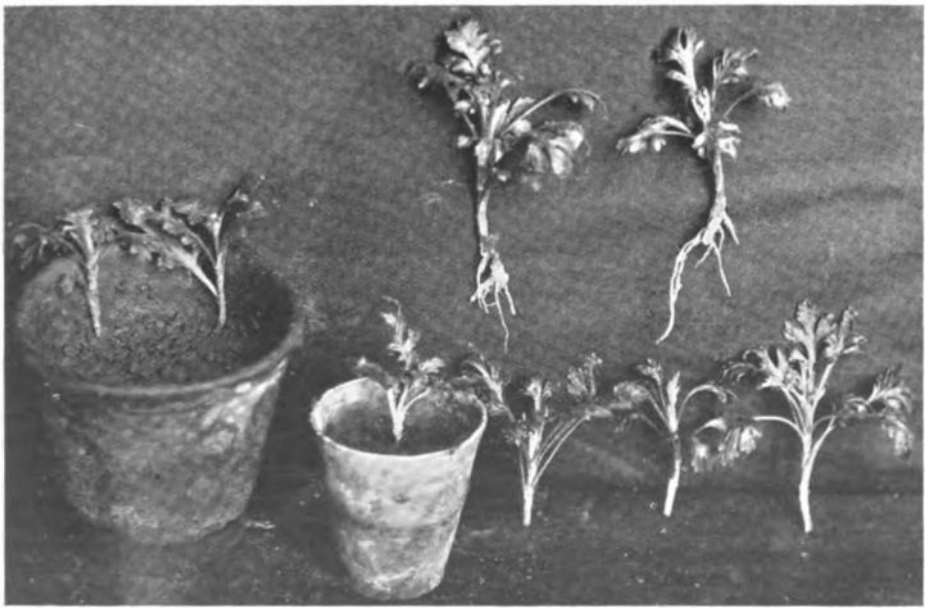
What to Do With Your Regal Pelargoniums Now.

AT the present time there are two sets of plants under notice: those which bloomed last spring and were subsequently cut back, and young plants which were struck from cuttings in July or August. Possibly the latter may have been kept in pans or boxes all winter and are ready for potting off. Now is the opportunity for attending to them. Four parts of old loam to one of leaf-mould and a good sprinkling of coarse silver sand will meet their requirements, and a 5in. pot will suffice for the largest struck cuttings. If old plants were not repotted last year, the same procedure should be followed with them, after shaking away some of the old soil from the roots. In their case an addition can be made of old manure broken up, that from a mushroom or cucumber bed, if available, will answer the purpose.

Cool treatment in all stages is best for regal pelargoniums. This means that during the winter the temperature of the house should be just warm enough to keep out frost and dispel damp. Air is essential whenever it can be given with safety, and it is often better to keep a little fire in the stove to admit of the ventilators being lifted, rather than keep the house close. The coolest quarter of a greenhouse, which may be on a shelf near the roof, or not far from the door, is often the best arrangement one can make, especially when other plants have to be considered; but wherever the position is, it ought to be one where they can be readily seen and easily attended to. During winter and early spring watering should be done sparingly, avoiding a too wet state, or too dry, the latter often accounting for the easy access of green fly and red spider in overheated houses. Sturdy grown plants ought to be the aim of the grower, and this is only achieved when they are grown under temperate conditions, and not too far away from the glass. These handsome flowering plants give the best results when given cool, rational treatment. It is when grown in extremes of heat that trouble begins, and those who have them in hand will be well advised to go slowly in the matter of heat, and, above all, not to forget that fresh air is necessary to their well being between now and their blooming period.—W. F.

Taking Chrysanthemum Cuttings.

THE present is a time when efforts should be made to secure a stock of healthy young chrysanthemum plants for next season. This is accomplished by taking cuttings—not of the stems or shoots of the old plant, but of the numerous shoots that spring up from the roots. These, if severed from the old plant, with roots attached, quickly make new plants, but much better specimens are evolved by the use of simple cuttings, *without* roots. Such cuttings can easily be taken when the new shoots are a couple of inches above the soil. The lower leaves are stripped off and the cuttings are planted around the insides of a pot containing sandy soil, where, in a few days, roots are produced freely, without applied warmth, under the shelter of glass. Then the little plants are potted up into small-sized pots, and thereafter shifted into larger sizes as the growth demands. A simple process that the veriest novice can undertake with success.—H. D.



SHOWING TYPES OF CHRYSANTHEMUM CUTTINGS BEFORE AND AFTER ROOTING.
Method of inserting cuttings round the side of a pot, and potting up rooted cuttings is also shown.

NEW SHOOTS SPRING FROM THE BASE OF AN OLD CHRYSANTHEMUM PLANT.
They quickly make new plants if cut away.

Starting Tuberous Begonias.

THE tuberous-rooted varieties are very useful for greenhouse decoration, and are easily raised from seed if a temperature of 50° to 60° can be maintained. A light sandy soil should be used for seed sowing. The seed pots or pans are best prepared and well watered some hours before it is intended to sow the seeds. The fine, dust-like seed should be carefully and evenly distributed over the surface, and should not be covered with any soil. After sowing, cover the pan with a piece of glass and shade with paper until germination takes place. By this method no watering should be neccessary until after germination. This is the best method of dealing with all fine seeds.

When it is necessary to afford water, stand the seed pan in a vessel of water. Damping often results from watering overhead, especially early in the year when there is not over-much light.

Where there are no facilities for raising seedlings, or one does not wish to trouble, it is an easy matter to get a display from dry tubers, which can be purchased or saved from year to year.

The tubers should be laid in boxes of leaf-soil and sand, placing them in a warm moist house with a temperature of 60° Fahr. When they have started into growth they should be placed in suitable sized pots, using at this stage a fairly light potting compost. Where such a high temperature cannot be afforded, an ordinary greenhouse will answer the purpose, in which case it is wise to defer the starting of the tubers until the end of February or March, giving them exactly the same treatment.

Fibrous-rooted begonias, the many fine varieties of which are commonly used for summer bedding schemes, should be much more generally used for greenhouse and general decorative work. They are easily raised from seed in the same way as the tuberous-rooted varieties; they are also easily

Digitized by Google

increased by means of cuttings, but basal shoots must be secured for this purpose. This class of begonia grows freely in any good potting compost, and succeeds in any ordinary greenhouse. A few of the best varieties are Bonfire, Pink Profusion, Prima Donna, Glory of Erfurt, Purity, Loveliness and Fairy Queen.

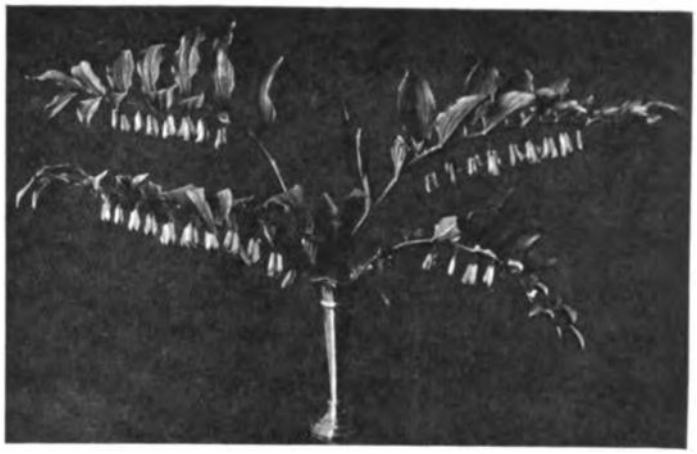
Present Treatment of Annuals.

ANNUALS raised from seed sown last September and intended for greenhouse decoration, should, as they require it, be placed in their flowering pots, which will vary in size according to the various subjects grown. While 5in. pots will suit small-growing plants, others, such as schizanthus, godetias, clarkia, mignonette, etc., will require pots 6ins. in size to do them justice. The potting soil should consist of a good medium loam with enough sand to keep it open and porous. Unless the loam is very heavy, I do not advise the use of leaf-soil in potting composts for growing annuals—without it, growth is much more sturdy and compact. When they have filled their flowering pots with roots, they can, if necessary, be assisted by feeding, using some approved fertiliser for this purpose, applying it strictly according to instructions. They should also be kept carefully staked and tied.

Where the sowing of seeds of annuals was neglected last autumn, it should be done now if it is desired to grow this class of plant for conservatory decoration. All the subjects generally used for this purpose can easily be raised in an ordinary greenhouse. To ensure success the chief points to be observed are, in the first instance, thin sowing, pricking off the seedlings before they are crowded, careful watering at all times, and cool treatment in a bright airy greenhouse. Annuals commonly used for this purpose are schizanthus, mignonette, godetias, clarkias, rhodanthes, nemesias, viscarias, Lobelia tenuior and Phlox Drummondii. There are, of course, many others that will suggest themselves to anyone interested in this class of plant.

Solomon's Seal in the Greenhouse

WHILE most people are familiar with the fact that lilies of the valley and bulbous roots arec apable of being brought into flower very early in the year by introduction to heat, it may not be generally realised that Solomon's Seal lifted from the garden ground will force very readily and will bloom very early in the year. This plant also responds readily to the much lower temperature of an "unheated" glasshouse. Roots taken up and potted now will soon produce shoots, and in a short time the beautiful arching stems with much larger and whiter flowers than those on the outdoor plant, will unfold.



SPRAYS OF SOLOMON'S SEAL MAKE FINE INTERIOR DECORATION.
The plant can easily be forced into early flowering in the greenhouse.

MAKING A GOOD LAWN

WHERE it is desired to make a new lawn, or remake an old one, no time must be lost in preparing the ground. It is most important that two or three months should be allowed for the settlement of the soil before anything like the laying of turves or the sowing of seed is attempted. If the surface is not really firm when the concluding stages in the making of the lawn are carried out numerous little hills and hollows are sure to appear. In the case of an old lawn, which it is wished to reconstruct, the grass should be stripped off to the depth of 2ins. Place this on one side and then proceed to dig the ground in sections to the depth of 9ins. Open out the ground to the depth of about 6ins. and replace the turves, bottom upwards, in the hole. Now fill in the soil, and if it is possible to add a layer of farmyard manure this is all to the good. New ground with rank grass should be treated in a very similar manner. Where the soil is water-logged or clayey, drainage should be provided by placing a layer of sand, ashes or rubble as a foundation. The surface of the ground where the lawn is to be should be left loose, and it must not be trodden on or the beneficial action of frost will not have full play.

There are, as has been stated, two ways of laying down a lawn, one from turves and the other from seeds. By following the former method it is possible to secure a lawn in the shortest possible time, but nowadays turf of good quality is not always easy to obtain and it is usually somewhat costly. A lawn that is secured by means of seed gives a sward that has a freedom from weeds, and this method is much the cheaper way of setting to work. Turf for a lawn is usually supplied in pieces 3ft. by 1ft., and its cost depends upon the local supply and the expense of cartage. The great thing is to see that it is free from rank weeds and without too great a proportion of clover. Before ordering the turf the area to be covered should be carefully levelled and otherwise prepared. Some kind of a beater will be needed, and this is usually formed of a square piece of wood, 2ins. in thickness and about 18ins. square, attached to an old broomstick which slopes from the wood at an angle of 45° and forms a convenient handle. This beater is made to beat the turves down so that they may lie well in place and take root freely.

Of course, the business of digging over the ground before turfing is one that calls for some care, as a level surface is important. A good plan is to dig in small sections and level by treading as one goes. Clear away any stones, and also free the ground from weed roots. It is an excellent idea to pass a small roller over the ground before actually beginning to lay the turf. Start in the middle of the plot when laying the turves and work towards the edges. Be most careful that the turves actually fit well at the joints and any faulty piece of turf should be kept at hand to cut up into small pieces for little repairs. When you have the turf down evenly go over it with the beater and then give the whole thing regularly. Do not trim the edges of the turf until the grass plants have really started growing, and then use a half-moon cutter in conjunction with the garden line.

Of course, the laying of turf can be carried out at any time during the winter providing the weather is mild. A lawn from grass seed is most successful of all if the sowing is carried out in April. When the ground has been prepared as described above, it should be left until the end of February. Then the levelling of the site must proceed as if for turf, and it is a good plan to set pegs in the ground at intervals of 6ft. and to make tests with a level straight edge across the tops of the pegs and a spirit level. When sowing a lawn it is best to make up the actual edging of the lawn first, and this may be composed of lengths of batten, creosoted, and nailed to pegs driven into the ground. The pegs should come on the side of the batten away from the lawn. Another plan is to make up a narrow edging of turf strips around the site. When the surface soil has been levelled rake into it the following fertilising mixture at the rate of an ounce to the square yard: 2lb. of superphosphate of lime, 1lb. of bone meal and 1lb. of sulphate of ammonia.

In April work up the soil to the tops of the batten, which should be about 2ins. above the ground adjoining the lawn. Again remove any stones or weeds and rake and roll the surface until it is quite level. It is most important to buy only the very best grass seed, and the surest safeguard is to purchase from a reliable firm. Choose a a dry day for sowing, and divide the plot into sections 6ft. by 9ft., and do one division at a time, allowing ½lb. of seed to each section. Sow the seed carefully and evenly; then rake it into the surface and cover very lightly with a mixture of dry soil and sand to which, if possible, has been added some bonfire ashes. To keep away cats the newly sown lawn may be covered with brushwood or netting. Another way is to have lengths of black cotton stretched between little stakes. Cats and birds, too, are very much afraid of cotton, and will never venture near when there is anything like this about.

A new lawn should be cut with great care, and the grass must not be touched until it is 2ins. or 3ins. long. Then use shears or a scythe, employing a board to stand on while doing the work. It is impossible to establish a good lawn where worms are present in large numbers. Where the wormcasts are very much in evidence, use one of the recognised worm killers, which, if handled according to directions, will not harm the grass but will certainly destroy all the worms.

When turves have been used in the making of a lawn it is of the utmost importance to keep a sharp look-out for weeds. These will start growing with great vigour very soon after the turf is laid, and they should be completely eradicated at once. If, during the first year of a turf lawn, weeding is thorough and systematic, there will be very little trouble later on.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

How to Prune Bay Trees in Tubs.

I have two standard shape bay trees growing in tubs. Would you be good enough to advise me as to whether they should be pruned. If so, correct date to do this, and also whether they require any special treatment. I find the branches droop, probably owing to the fact that they ought to be pruned.—W. J. B., Surbiton.

The second half of April is a good time to prune bay trees. If they make much new growth during the summer, prune again at the end of July. Shorten the growths sufficiently to keep the trees to the formal standard shape. It is not natural for the growths to droop. This suggests that at times the roots are allowed to become very dry before water is given.

Cherries for a Small Orchard.

Will you kindly tell me the best cherry trees to plant for a small cherry orchard, on a field sloping and facing south-west, exposed to wind, but well drained. Soil, I think, the same as the rest of the field, clayey loam; a good many stones work up in the part I have made into a kitchen garden. There is no shelter except by the hill which protects from the east. I want to plant about three dozen standard cherry trees for fruit. Would a clump of wild cherries planted near spoil them? These I only want for their beauty. Please give me any directions or advice as to the idea of this small cherry orchard. There is none about here.—M., Taunton.

The cherry trees should do quite well in the soil and position you describe. The best varieties to grow are as follows:

Early Rivers, black, ripe end of July.
Governor Wood, red and yellow, early July.
Bigarreau Schrecken, black, early July.
May Duke, dark red, July.
Napoleon, red and yellow, August.
Black Heart, July.

If you have space for two dozen trees, you might plant four of each of these, or six of each of the first four named. They are all reliable croppers when treated rightly, and planted together would cross-pollinate one another successfully. As standard trees they should be planted not closer than 20ft. apart each way. Probably a good dressing of lime to the land before planting, and light dressings every third or fourth year afterwards, would be advisable if your soil is of a clayey nature. A clump of wild cherries planted near would be an advantage if anything. However, instead of planting the wild cherries, the fruit of which is of little value, why not plant trees of Kentish Red and Flemish Red? The scarlet fruits of these varieties are excellent for cooking, and are extremely decorative, as are the white blossoms in the spring.

A Climber for a Tennis Court Surround.

I have a tennis court which is surrounded by wire netting 12ft. high. It is shielded by buildings on its west side, and I want to grow some form of climber along the two ends which run east and west. The soil is light, with chalk about 18ins. down. Would you advise as to a suitable type and as to the distance apart it would be necessary to plant? I would prefer a type with bright-coloured flowers, or else flowers which are dead white.—R. A. C., Andover.

The position described appears to be well suited for the climbing rose Albéric Barbier. This has lustrous green foliage which is evergreen, and white flowers. As it is free in growth, 12ft. will be a suitable distance for planting. As the soil is light, work in old decayed manure previous to planting.

Preparing Soil for Rose Beds.

I shall appreciate advice on the following: I have in my garden a rose-bed, size about 40ft. by 15ft. The situation is good, open, sloping to the south. The soil is also good, but a very light sandy loam. I have difficulty in obtaining cow or pig manure, but I can get plenty of clay. How do you advise me to apply the clay in order to make the soil more retentive of moisture? Should it be placed under the roses as a foundation, or spread on the top to keep the moisture in, or broken up and dug into the soil? In dry summer weather my roses go off very quickly owing to the dry nature of the soil.—H. E. C., Weston Favell, Northants.

The proper way to apply clay to a light soil is to spread it out in a lumpy condition on the surface in October. If left so through the winter the lumps will crumble like powder in spring, when it should be lightly forked into the surface soil. Many years ago grassland was "marled" regularly—a blue-coloured clay spread on the surface. If dug into the soil while in a fresh, adhesive state, it will remain so as long as it is buried. You should, this coming spring, lightly bury some of Wakeley's Hop Manure in your rose-beds.

Types of Fruit Trees to Grow.

In a recent issue I notice your advice against standard fruit trees. Is this because space was a consideration or because standard and half-standard fruit trees are not beneficial from the point of view of excellence of crops? In my garden half-standards are preferred at the beginning of forming an orchard where space is fairly plentiful.—E. H. York.

Regarding apple trees, pyramid and bush trees are recommended in preference to standard and half-standard trees in consideration of space, but more particularly because they bear fruits much earlier and more freely when the trees are young. Over a long period of years when space is not important, standard and half-standard trees are preferable. Half-standards are easier to prune when young and the fruits more easily picked. Standards are recommended when the ground beneath and between is cropped, where cattle sometimes graze, or the grass is cut for hay.

Late-Keeping Grapes.

I have a house of Muscats and want to put in two of the best grapes for keeping late in the season. What kind do you recommend? My Muscats did not finish well this year and went off very early. I am relaying the vine pits. What do you recommend to rectify this?—F. R., Ascot.

The two best varieties of grapes for growing in the same house as the Muscats are Alicante and Lady Downes. Both are free-fruiting, and Lady Downes is good flavoured for a late black, and will keep very late in a sound condition. Of course, all late grapes should be started not later than the first week in March, and be coloured and matured by the first week in October to keep well. Late-ripened grapes do not keep satisfactorily. Use fibrous loam and finely ground bones in the renovation of the border, and feed with Thomson's Vine Manure from May to September judiciously.

Fragrant Shrubs for a Lawn.

My front garden consists of two lawns, one square, the other triangular—about 6ft. by 15ft. by 20ft. As an experiment I want to plant the triangular portion with fragrant flowering shrubs and to naturalise bulbs in the remaining grass. If I like the effect I shall repeat the programme in the square lawn. Would you kindly let me have the names of suitable shrubs—preferably some that can be grown fairly quickly and readily from seed—or shrub-like perennials, about six to ten, and as many fragrant as possible? Soil fairly heavy clay with a fair amount of builders' rubbish mixed in it. House faces due north.—R. J. R., Wembley.

We should suggest the following shrubs as being suitable for your purpose: Philadelphus microphyllus (fragrant), P. Lemoinei erectus (fragrant), P. Virginal (fragrant), Hypericum Henryi, Berberis stenophylla Lonicera fragrantissima (fragrant), Chimonanthus fragrans (fragrant), Cytisus albus, Kerria japonica flore pleno, Spiræa prunifolia flore pleno, Buddleia variabilis and Daphne Mezereum (fragrant).

Pruning Apple Trees.

Will you kindly advise me as to the best method of pruning apple trees? I have three in my garden about eight years old. They have not borne much fruit for the last two years, and I think, perhaps, I have not pruned them properly.—J. T., Coventry.

When pruning apple trees the ideal at which to aim is an open-centred tree, with evenly spaced branches radiating from the top of the stem, no one branch crowding or crossing any other. At eight years old the main branches of the trees should now be well formed and subsequent pruning ought to be on these broad lines. Cut back all young long side shoots to two bottom buds and shorten the leading or extension shoot of each branch by about one-third. Side shoots that are 4ins. or less in length may be left uncut; they will make fruiting spurs naturally. If the trees are trained as standards, then there is no need to shorten any but those side shoots that tend to crowd the centre of the tree or interfere with the smaller branches. Of course, at eight years the trees are just settling down to fruit, and we should not, in the circumstances, have expected them to bear heavy crops before this.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2878 Saturday, January 29th, 1927 Price TWOPENCE

Plate No. 1 *in the* RYDER CATALOGUE, "Everybody's Flowers," *by Miss Winifred Walker.*

"Everybody's Flowers"

By Miss Winifred Walker

THIS picture represents a charming group of those homely flowers that everybody loves—Marigolds, Forget-me-nots and Aquilegias (Dancing Fairy Flowers). This is but one feature of the new Ryder Catalogue which everybody should possess before planning their 1927 garden. The Catalogue also contains particulars of a new and interesting Competition—additional coloured plates and black and white illustrations, together with a full list of Ryders Seeds sold in popular 2d. packets, and a host of informative cultural hints.

NEW GROUP OF GLADIOLI

Ryders Hybrids of Primulinus.

Some few years ago a traveller discovered a beautiful golden Gladiolus near the Victoria Falls in South Africa. This variety is the parent of a wonderful group of Hybrids that are offered by Ryders, *i.e.*, Primulinus. The spikes are far more graceful than any of the family and the colours are in wonderful variety. They may be styled and are best known as Tea Rose colours, such as Salmon, Pink, Citron, Scarlet, Cream, etc. For cutting they are glorious, for garden decoration, indispensable. Ryders offer a mixture in which there are not two alike, at the following prices :—

Per doz.	..	..	2/6
25	..	..	4/6
50	..	..	8/6
100	..	..	16/-

VOL. XCI.—No. 2878. JANUARY 29, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

The Preparation of Seed Pans and Pots.

EVERYONE at the present time is thinking about seeds and sowing; in other words, of supplying about 80 per cent. of the crops of an average garden by means of plants grown from seed. Of these, a large proportion are sown outside, and this, at the moment, does not concern us. What may be of assistance to many amateurs are a few notes regarding the sowing of seeds inside. Failure is usually due to three main causes—lack of cleanliness in the pan or pot, absence of sufficient drainage, and the too thick sowing of the seed. Pots that have been stored after the past season, whether washed or not before storage, should be thoroughly scrubbed, rinsed in clean water and dried before use. This will ensure that all mould is removed. Drainage is also a matter of the greatest importance, particularly when the seed does not germinate immediately. Many beginners imagine that it is sufficient if they bottom the pot or pan with a good layer of broken crocks; but that is not enough, for if the potting compost is too heavy and sticky the water will not percolate through and stagnation occurs. When the local soil is gritty or sandy, and so is open, there may be no necessity to add extra sand to the compost, but the heavier the soil the more sharp sand must be added. A good test is to squeeze a lump of your compost in your hand; if it breaks into particles at a touch it is of a good consistency. On the other hand, if it remains a sticky, adhesive mass, it will cause stagnation. Potting mixtures vary according to the local soil, but where this is average loam a good all-round mixture can be made from two-fifths loam, two-fifths leaf-mould and one-fifth sharp sand.

The third cause, that of over-thick sowing, is one which is only too often practised. Seedlings require light and air as much as full-grown plants, and if they are sown too thickly the seedlings on germination will grow thin and weedy in their effort to get light and air. In addition a crowded seed pan is always more liable to an attack of damping off. It will be seen, therefore, that many plants, even at the tiniest stage, should be treated as individuals and not as a mere mass of seedlings.

Two points which often puzzle beginners are the requisite amounts of air and light that should be given tiny seedlings. The first can be dismissed with the advice that the air should never be stagnant, nor should the circulation be so great that the seed pans are in an actual draught. The second requires more individual attention; so long as the seedlings are inside it should be the object of the grower to see that the growth is firm and healthy and that the seedlings are not long and weedy, which tends to soft, sappy growth and renders them more liable to injury and disease. Obviously the two extremes are scorching from too much sun and sappy growth from absence of light. The gardener should aim at a happy mean. With our peculiar climate it is better to use temporary means for shading, such as old newspapers, than more permanent means that are often employed, such as painting the outside of the glass of the greenhouse. It takes little or no time to cover the seed pots and pans with newspapers, and they are as easily removed. It is amazing how quickly plants respond to the presence of light, but it will be found that even on the brightest days in the next two or three months a covering need only be used for two hours in the middle of the day.

International Rose Conference July, 1928.

IT has been decided to hold a great International Rose Conference in London in the beginning of July, 1928, to focus the world-wide interest in the rose. On the first day a rose show will be held to give raisers of all countries the opportunity to exhibit their best productions and, if possible, demonstrate the steps which have led up to them. Awards of cups, medals and certificates will be made.

The second and third days will be devoted to the Conference proper, and distinguished raisers and growers will be invited to submit papers on "The Genetics of the Rose," "Fungus and Other Pests," "The Future of the Rose as a Decorative Flower," "The Future of the Rose as a Market Flower," "Roses under Glass," and "Rose Species." British (including Australian, New Zealand and Canadian), Continental and American experts will be invited to contribute to this programme.

Visits will be planned to Kew, where a fine collection of roses is well grown, and also to several of the leading nurseries.

The time table proposed is as under:

June 29th and 30th	National Rose Society's Summer Show.
July 1st	Sunday.
July 2nd	Visit to Kew.
July 3rd . ..	Visit to Colchester Nurseries.
July 4th	Conference, Rose Show and Dinner.
July 5th and 6th..	Conference.
July 6th	Evening—Soirée.
July 7th	Visit to Lea Valley Nurseries.

If raisers in Australia, New Zealand, Canada, or the United States would like plants of special varieties grown in Britain so that they could exhibit some flowers of such at the Conference, they are requested to get into touch with nurserymen whom they know, asking them to grow the plants. A number have already promised to do so, and to treat the plants as if they were absolutely the property of the senders. Raisers who may not know nurserymen personally in this country, are invited to write to the Secretary of the National Rose Society, who will make arrangements to have the plants grown. Every care of plants sent under this scheme would be taken, and precautionary measures as far as possible be assured. In the case of Continental growers this may not be necessary, as flowers can now be sent by air in a few hours.

The Secretary of the National Rose Society, 28, Victoria Street, Westminster, S.W.1, will be pleased to furnish any further information to all interested rose growers.

HAVE YOU

- ¶ *Pruned your autumn fruiting raspberries?*
- ¶ *Planted out some Jerusalem artichokes in well prepared soil?*
- ¶ *Sown annuals of all kinds in your warm greenhouse? Some of the half-hardy kinds can be used for decorating the greenhouse, the others can be planted outside.*
- ¶ *Made small sowings of tomatoes, onions, leeks and cauliflowers if you have a warm house?*
- ¶ *Sown some radishes, lettuces and shorthorn carrots in frames on a mild hot-bed?*
- ¶ *Sprayed your gooseberry bushes with lime-sulphur to prevent birds from eating the buds?*
- ¶ *Dressed your lawn with lawn sand?*

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 9, which appeared in our issue of January 15th, have been awarded to

Mrs. R. J. Young,
Red Hatch, Ascot.
and
A. E. Bateman,
4, Elmwood Avenue, Feltham.

To each of whom a cheque for that amount has been sent.

SCARLET AND GREY IN THE GARDEN

Novelty in arrangement and colour scheme is always to be aimed at in the garden in order to avoid monotony. Here is an idea which many amateurs may like to try. A useful selection of subjects is given for the purposes of experiment.

FINE colour though it is, scarlet is often found difficult to manage in a mixed border. It disagrees horribly with pink, crimson and nearly all shades of purple; it makes far too garish and crude a combination with blue or yellow (except orange verging on scarlet), while, although it does not, of course, clash with white, the contrast is apt to be a little too sharp to be quite pleasing. It is most satisfactory when softened by grey, grey-white or blue-grey, and such a combination is seen at its best in a short but fairly wide border of irregular shape, or filling an angle where two mixed borders meet, the colours of the latter being so arranged that they lead up through cream, yellow and orange to the scarlet.

There are not many tall plants with scarlet flowers, but some of the torch lilies reach a height of 6ft. and are nearly true scarlet. Of these, Kniphofia aloides glaucescens is one of the best. The new late-flowering variety, K. Nelsoni Colesborne is, perhaps, a purer colour, but it is only about 4ft. high and is more suitable for the middle of the border. There are, however, two scarlet climbers, which, under favourable conditions, may be grown on poles or a treillage at the back of the border; these are Lonicera sempervirens, the beautiful trumpet honeysuckle and Clianthus punicens, the glory pea, but, unfortunately neither is quite hardy save in warm districts, the glory pea being the tenderer of the two. This is by no means a rampant climber, rarely reaching a greater height then 5ft.

Among the most desirable scarlet blossomed plants of moderate height, that is to say, from 3ft. to 4ft., are the Oriental poppies, of which Papaver Taplow Scarlet and Goliath are specially brilliant in colour. Lychnis chalcedonica, Montbretia Fire King, Gladiolus brenchleyensis, Lilium chalcedonicum, Phygelius capensis, the Cape figwort, and the two scarlet Delphiniums cardinale and nudicaule. The figwort and Delphinium cardinale grow from 3ft. to 3ft. 6ins. high and both are dubiously hardy in the colder parts of this country. The first named needs as much sun as possible, does not mind drought in the least, and is happiest in a sheltered place near the sea, where it will produce its racemes of gorgeous flowers freely. Delphinium cardinale is less tender, but calls for some root protection in winter, especially if the soil is cold and damp. The dwarfer and more compact D. nudicaule, which is useful for a dry border, will stand some degrees of frost, but it is wise to give it a mulch of ashes before cold weather sets in. The beautiful Lobelia cardinalis from North America is tolerably hardy in warm, moist soil, but it is safer under any conditions to lift and winter it in a cold frame. Queen Victoria is a good old variety of this fine plant, but there are several newer ones. I believe the result of crosses with the Mexican L. fulgens—some of which have green and some dark purple bronze stems and foliage, while the flowers vary in brilliance. The best are Lord Ardilaun, Gloire de St. Anne, Firefly and Huntsman.

THE ARTEMISIAS PROVIDE SOFT GREY TONES IN THE BORDER.

Dwarf-Growing Sorts.

Scarlet plants of lower growth, suitable for the front of the border are Geum Mrs. Bradshaw, Potentilla Gibson's Scarlet and Mimulus cardinalis, the last named, however, is not to be recommended for a very dry situation. There are some good scarlet annuals, including Alonzoa Warscewiczii—a big name for such a little plant!—of which Sutton's Compact Scarlet is a satisfactory dwarf (9ins.) variety, A. gracilis being taller and more branching in habit; Cacalia coccinea (18ins.), the pretty tassel flower; Gilia coronopsis (really a biennial but best treated as a half-hardy annual), Dianthus Heddewigii Scarlet Queen (single and double strains), and, of course, the ever useful nasturtiums, of which the dwarf King of Tom Thumbs, with its glowing red flowers and dark leaves, is admirable as an edging.

THERE ARE FEW SCARLET FLOWERS TO EQUAL THE POPPIES.

Plants with Grey Foliage.

To provide the grey tones desirable to blend with and soften the rather hard brilliancy of the scarlet flowers, foliage must be chiefly relied on, but there are at least two grey clematis, Lady Londesborough (patens section) and Otto Froebel (lanuginosa), which may be grown on poles in the back row and both flowers and leaves of Eryngium giganteum and Echinops niveus are grey. Those of the echinops—which grows 5ft. wide—are, indeed nearly white. In my garden I have some old clumps of a tall flag iris of a delicate grey shade which blooms at the same time, June, as the scarlet Oriental poppies, with happy effect. I do not know its name, but of the newer varieties, perhaps Willie Barr is the nearest to it. The effect of Gypsophila paniculata, when in flower, is that of a silvery cloud and it should be freely introduced among the scarlet flowers. If clumps of it (single or double) are planted immediately behind the big poppies, a very little coaxing will induce its feathery branches to conceal the former in their ugly, after-flowering stage. The shrubby Santolina chamæcyparissus makes neat little grey bushes if carefully pruned and there are two silver-grey salvias, S. argentea and S. Sclarea, the latter, rather oddly,

Digitized by Google

harmonising quite well with scarlet in spite of the fact that its bracts are tinged with pink when they first open. For the front of the border there are Cerastium tomentosum and C. Biebersteinii; Artemisia Stelleriana and A. frigida. Stachys lanata, the well known Lamb's Ear, all of which are from 9ins. to 12ins. high, and to the list may be added an annual, Omphalodes linifolia, which has greyish glaucous leaves.

It may be added that if the border is a wide one, young trees of Eucalyptus globulus, E. Gunnii (hardy enough in their youth, although short lived in our climate), and Hippophae rhamnoides (sea buckthorn), all of which have silvery-grey foliage, may be planted in the background with excellent effect.

R. E. HEAD.

NEWER AND BETTER SWEET PEAS

QUITE a number of really good varieties of sweet peas have been introduced during the past two or three years, some of them outstanding improvements. For the benefit of those readers who are not in close touch with sweet pea matters, I will discuss the best of recent introductions in brief detail under the most popular colour sections.

White.

Since the time of the old favourite, Dorothy Eckford, many whites have come and gone, few of them attaining real popularity. No matter how small the collection of varieties, every grower must have a white. At the present time, Constance Hinton holds premier position; but there are two new ones, either of which may take the place of Constance in the near future. Avalanche is undoubtedly the best white-seeded white in commerce, a great improvement on Edna May, Florence Wright, etc. It is pure and opaque, with plenty of substance, a large-flowered, long-stemmed and vigorous-growing variety which has greatly pleased me. The other newcomer is Model, a dark-seeded novelty closely resembling Constance Hinton. White Lady is another good variety, perfectly fixed, and ahead of many in its class.

Pink.

The first variety of the waved or frilly petalled type was a pink, Countess Spencer, and there are many, many shades of pink and numerous excellent varieties in this colour section to-day. Mrs. Horace Wright, a medium pink flushed on white ground, is one of the largest, if not *the* largest flowered variety we have, a first-class pea for any purpose, very vigorous, long-stemmed and an ideal form. Carmelita is really a brighter coloured Mrs. Horace Wright, but not quite so large or robust. Nevertheless, it is a fine novelty. A rather startling and uncommon shade of pink is found in Tom Sykes, which is richer and much brighter than Hawlmark Pink, with almost the same habit of growth as that variety. A rich salmon pink well worth a place in any collection is Mrs. Chas. W. J. Unwin, very large and vigorous. It must be said, however, that its colour tone is slightly variable. Gladness was illustrated in colour on the back cover of THE GARDEN, August 28th, 1926. It is a new shade, a light coral pink. Another dainty and attractive pea is Supreme, of a china pink. Delight is another good variety of a delicate shade of salmon pink. It is a fairly vigorous grower and does well under glass.

ONE OF THE MOST STRIKING SWEET PEA NOVELTIES: PIMPERNEL, VIVID SCARLET.

Cerise.

There was a time when every variety in this colour section was weakly growing and small flowered. Now, we have two of the most vigorous of all in the bright cerises, Charming and Coralline. Both are large-flowered, exceedingly vigorous, and alike useful for garden and home decoration as for exhibition purposes. These two are very similar except that Coralline is slightly the richer and deeper coloured. With the rise of the cerise colour class, one has noticed a corresponding decrease in public favour of the carmines and roses, which are now rarely required in small collections. Centaur and Peggy are another pair, very much alike in colour and habit. While they are not quite so tall-growing as Charming and Coralline both are robust, large-flowered and even more richly and warmly coloured than Coralline. One of the most distinct novelties of recent years is Del Monte, a rich salmon cerise pink. It is a good pea in every way and, I think, should be classified as a cerise rather than a pink. In artificial light it is superb, seeming to glow.

IVORY PICTURE, A VIGOROUS AND LONG-STEMMED VARIETY.

A CHARMING BLOOM OF HAWLMARK PINK.

Scarlet-cerise.

Grenadier, the improved Royal Scot, is already well known and popular. It is a bright geranium red and, like all varieties mentioned in this section, is perfectly sunproof and, indeed, seen at its best in bright sunshine. Pimpernel is practically identical. Possibly 2LO should be called a true scarlet, it is so vividly coloured. In sunny weather, it is most intense and glowing, a fine pea for garden decoration or for any purpose, and a great improvement on the older variety Wonderful. Delightful is another brightly coloured variety which was well illustrated in colour on both back and front covers of THE GARDEN, August 28th. A 1926–27 novelty, Daventry, seems midway in colouring between the cerises and the scarlet-cerises. It is a beautiful shade of orange-red or red-cerise. Just as the cerises have somewhat replaced the roses and carmines, so the scarlet-cerises—being bright and sunproof — are reducing the degree of popularity formerly enjoyed by the orange-scarlets.

Cream.

What Joy is probably the deepest coloured new cream, a large and vigorous improvement on Daffodil. Leslie Rundle is lighter, but a large, robust and long-stemmed pea of some merit. Cream Perfection is an improved Matchless, which can be recommended to exhibitors. A variety which has impressed me very favourably this season is Ivory Picture, the colour of old ivory. It is long-stemmed, very robust and large, but with a tendency to show a pinkish flushing if green fly are allowed to get a hold on the plants.

Blue.

While the ideal blue has yet to be raised there are one or two attractive varieties among recent kinds. Heavenly Blue is a bright and

Digitized by Google

clean medium blue which, for colour alone, I like better than Mrs. Tom Jones or Bluebird. It is a fine garden pea. Blue Butterfly is about the best of the pale blues, a silvery lavender-blue, dainty and sweetly scented. Both Royal Blue and Fortune are deep navy with a violet sheen, rich and bright, after the style of Commander Godsal or Jack Cornwall, V.C. As a rule, the dark blues object strongly to adverse weather conditions. Royal Blue was illustrated in the August 28th number of THE GARDEN. It is a nice point whether Black Bess should be included among the dark blues or the black-maroons, for it falls about midway between the two. Perhaps it is best described as a bronzy, deep blue with a glossy metallic sheen.

Crimson.

There are only two new crimsons of note, both very much alike in colour—Sybil Henshaw and Red Gauntlet. Sybil is a bold, massive blood crimson, very vigorous and sunproof and an excellent pea in every way, which, I feel sure, will displace Charity. Red Gauntlet may best be described as an improved Crimson King.

Lavender.

While there are many shades of lavenders in commerce, the three I shall mention are all more or less alike in tone, and quite distinct from the most popular lavender at present, Powerscourt. Wistaria is reminiscent of that old favourite grandiflora variety Lady Grisel Hamilton, a bright, clean lavender with a blue shading. Mermaid is very similar, slightly lighter and a trifle larger than Wistaria, while Gleneagles is a clean bright tone which cannot fail to please. All three are robust and long-stemmed.

Purple.

I have seen two really good new purples this season, both rich solid self colours. One was Olympia and the other a seedling sent to the N.S.P.S. trials by Messrs. Sutton. The latter may be introduced this season, but at the time of writing I have not heard its name. Both are, I feel confident, substantial improvements on Royal Purple.

Mauve.

Just now we are having something of a deluge in the way of new mauves; but it is a colour section in which improvement was needed. Last season, Mauve Beauty was placed on the market, and this year (1926–27) we have Chieftain, Royal Mauve and Guardsman, to name the four best. All are first-class varieties and improvements on older kinds, such as King Mauve or Lady Evelyn. There is very little to choose between them; but I, personally, like Chieftain best.

Cream-pink.

In no colour class has there been greater advance made during recent years than in this. In the salmony cream-pinks we have three very rich and delightfully warm-toned varieties in W. J. Unwin, Miss California and Magnet. It is purely a matter of personal taste as to which is considered the best. Miss California is the deepest coloured, W. J. Unwin the largest flowered, and Magnet the richest. All are good garden and decorative peas. In lighter and, perhaps, daintier tones we have Venus, Mary Pickford and Delight. The first-named is really an improved Mrs. Arnold Hitchcock, large and extremely vigorous and long-stemmed. Mary Pickford is frilly, a soft, dainty and very pleasing pea indeed. Delight is best described as a salmony-apricot pink on cream, soft yet very rich. It should be shaded in sunny weather to preserve its delicate colouring, and needs good culture.

A Good Dozen.

My personal choice of a first-class dozen from among the various kinds I have mentioned above, one from each colour section, would be as follows: Avalanche, Mrs. Horace Wright, Coralline, Grenadier, Ivory Picture, Heavenly Blue, Sybil Henshaw, Mermaid, Olympia, Chieftain, Miss California and Lilac Queen. All these are excellent general-purpose varieties, with no "fads and fancies," and likely to conform to average tastes. C. H. A. S.

THE FLOWER GARDEN

A Good Wall Shrub.

THE genus cotoneaster has been considerably enriched of recent years, and so much space devoted to the new species and varieties that it is possible for the older members to be partially forgotten. In this category is the distinct C. horizontalis, or herring-bone cotoneaster, a name which visitors often bestow on this plant during the winter months when it has lost its leaves and berries.

It hails from China, and is a deciduous, low shrub from 2ft. to 3ft. high, therefore it is admirably suited for low walls. Facing large rocks on the rock garden it is quite at home, especially if stones are chosen for their width rather than the height. Here the true character of the plant will be revealed, as the branches extend in a horizontal manner. These are clothed with roundish green leaves, and the small white pinkish flowers appear in May. It is, however, the bright red fruits which are noteworthy. They are produced in quantity, and are at their best during the autumn months. About this period the foliage begins to change to reddish tints, and by the end of December the branches are bare. In addition to covering low walls, it can be used in the front rank of the shrubbery, where it will form a flat-growing shrub. I have this cotoneaster growing in several positions, but the best fruiting examples are found where there is a fair amount of sunshine. It is quite hardy, and should be planted before the growing season begins. Propagation is effected by cuttings, which readily form roots in a cold frame, but as a rule plenty of seedlings will appear in close proximity to the old plant, if the conditions are favourable to germination.

I have fruited several dozens of seedlings, and so far have not seen any departure from the type. It is an easily-grown plant, and is one well adapted for small gardens.—T. W. B.

COTONEASTER HORIZONTALIS, WITH ITS SPREADING SAIL-LIKE BRANCHES, MAKES A GOOD SUBJECT FOR WALL DECORATION.

A Free-flowering Broom.

PLANTS are often required for the rock garden that will effectually drape a large stone or rock, and at the same time furnish a good display of bloom in due season. In Cytisus kewensis we have an ideal subject for this purpose, for it is indeed a lovely plant raised at Kew in 1891 from C. Ardoini and C. albus. Being of hybrid origin, it is necessary to increase it by means of cuttings. It is a low procumbent shrub, 6ins. or 8ins. high, but once the roots become established it will grow freely, and form a dense mass several feet in diameter. During April and May the plant will be in bloom, and the long trailing shoots form a perfect cataract covered with cream-coloured or pale sulphur-yellow flowers. These are about half an inch across, and somewhat similar to C. præcox, but rather larger than that species. Altogether it is one of the finest plants for the rock garden, while it would also be a decided acquisition for planting on the top of low walls, where its trailing growths when in bloom could be seen to the best advantage. C. kewensis, like other members of the genus, is easily grown, and is not particular in regard to soil, providing it gets the brightest spot in the garden. This choice member of the broom family can be planted at any time, because it is grown in pots by the trade. Owing to the fact that it transplants badly it is wise to select its final station carefully and then to get it planted while still on the small side. —CHEPSTOW.

Japanese Anemones for the Shady Border.

FEW plants make a finer display from August to October than the various forms of A. japonica, or the Japanese anemones, a name by which they are popularly known. They are first-rate herbaceous subjects for border or permanent beds, and one often sees a delightful clump in cottage gardens, especially the old Japanese white anemone, which is still one of the best. This attains a height of 2ft. or 3ft., the elegant foliage and the large open saucer-shaped pure white flowers are always effective. They are ideal for cutting purposes, and when planted in a bold clump no plant in the border will be more conspicuous during the early months of autumn. The type A. japonica is similar to the above, but the flowers are clarety red and hardly worth a place in these days when so many other fine varieties are available at so small a cost.

Among the white forms will be found Honorine Joubert, which

Digitized by Google

is a great favourite, while a semi-double snow white is Whirlwind, a really fine plant well worth growing. An exquisite and beautiful variety is elegans, sometimes known as rosea, which produces large silvery or soft rose flowers, while rosea splendens is a pretty soft clear rose.

Another with rose-tinted flowers is crispifolia, the foliage being beautifully waved, reminiscent of some of our greenhouse ferns. This is worthy of a place for foliage alone, which comes in useful for mixing with other varieties when employed as cut flowers. I always grow a few plants for this purpose. Lady Gilmour with light rose flowers is somewhat similar to the preceding regarding the finely cut and crisped foliage. Lovely is extra good, the semi-double large flowers being a delicate rose pink, and another of the same tint is Mont Rose. Several others could be mentioned, but for those who only need the best, sufficient has been quoted; while for about sixpence a plant a good mixture of varieties can be obtained from most advertisers in THE GARDEN.

All the Japanese anemones will thrive in ordinary garden soil, and while a fairly sunny position should be chosen they do not mind partial shade; in fact, I have seen them naturalised in open spaces in woods.

Now is a very good time to plant, and when once planted they should be left alone for several years, as they somewhat resent root disturbance; a fact to be borne in mind when digging over the herbaceous borders.—T. W.

A Neat Plant for the Rock Garden.

THE incarvilleas are few in number, but Incarvillea grandiflora is a great improvement on the old I. Delavayi, and it should be chosen for this reason. Moreover, it is a smaller-growing plant, therefore suitable for nooks in the rock garden, while it is also an acquisition for the borders. It attains a height of about a foot and its bright rose alla-manda-like or gloxinia-shaped flowers are produced in June and July. This charming plant has been awarded a F.C.C. by the Royal Horticultural Society and such a high award has been fully justified by the admirable results obtained by ordinary cultivation. I grandiflora is of Chinese origin, and now we have a handsome variety in brevipes, with large purplish-crimson flowers marked with white. In both these plants the greater intensity of colour is in marked contrast to I. Delavayi, they are more compact in habit, and are suitable for the small garden. During the winter the fleshy roots are dormant, therefore this is a good time to plant fresh clumps. They delight in a deep, well drained soil, which is not on the heavy side, and, for preference, a sunny spot should be chosen. In the rock garden will be found several ideal nooks for this plant, and say, if six roots are placed in one patch, the effect will be most bright and attractive when they are in flower. On the top of each thick root will be found the crown or growing point, and if slugs are prevalent these crowns often get damaged during the inactive period. A good layer of sharp sand will generally keep these marauders at bay.—GLOUCESTER.

Sea Pinks for Edgings and Borders.

THE sea pinks or thrifts, the names by which the armerias are known, are a charming family with thick tufts of grass-like foliage and heads of showy flowers. The finest of all the armerias, however, is Bee's Ruby. It is a robust and strong-growing plant, and is undoubtedly the richest coloured of the group. When in bloom it is about 18ins. high, and the numerous heads of large, handsome, warm rose pink flowers are sure to be admired. This is probably a form of the giant thrift, A. latifolia, but a great improvement on the type. The armerias, and Bee's Ruby is no exception to the rule, will succeed in any ordinary garden soil and almost any position except dense shade. They are admirably suited for edgings to a flower border, for crevices in old walls and rocks, and for producing a display on the rock garden from May till July.

THRIFT MAKES AN EXCELLENT EDGING PLANT. IT GROWS WELL IN ANY ORDINARY GARDEN SOIL AND IS FREE FLOWERING.

When there is a good stock the most ready means of propagation is by division, which can be done at any time from now till early spring, but with a limited stock of plants or rare varieties every opportunity should be taken to increase them. During August a number of the side shoots could be removed, and these will soon form roots if placed in sandy soil either in a cold frame or partially shaded border.

A most suitable companion to Bee's Ruby is Vindictive, a variety of great promise, and one that I have found excellent in every way. On the rock garden it has grown freely and is often in bloom. The flowers on 6in. stems are a deep crimson, and a fairly large patch would be most effective.—T. W. BRISCOE.

Trees with Coloured Foliage.

IN addition to the purple and copper beeches, and the variegated elms, there are numerous deciduous trees which are to be recommended on account of their coloured foliage. The variegated kinds of Acer Negundo are specially striking. Of these the following, which are small-growing and will stand a good amount of pruning, are worthy of note: foliis marginatus aureis has golden variegated leaves; variegatum has silver variegated foliage; and californicum aureum leaves of a bright gold colour. Another interesting golden tree is Catalpa bignonioides aurea. This keeps its colour well through the summer. A beech with golden leaves is Fagus sylvatica Zlatia, but here the colour declines towards the end of the season. There are also some silver-leaved varieties of beech, but none of these is very striking. Fraxinus excelsior aurea is a fine golden-leaved ash, and another form is known as F. americana aucubæfolia. Idesia polycrapa is worth growing for the sake of its large heart-shaped leaves, which have bright red stalks. The cherry plum (Prunus cerasifera atropurpuræa) is a very handsome purple-leaved tree which keeps its colour well. As is well known, this prunus is one of the first of the spring-flowering trees to bloom. P. Persica foliis rubris is another good purple-leaved tree. Pyrus vestita is a handsome silver-leaved tree from the Himalayas. Another golden tree worth growing is Robinia Pseudacacia aurea, which is really very handsome.—S. L. B.

A Hardy Rock Rose.

THE laurel-leaved cistus, C. laurifolius, has gained the reputation of being the hardiest of the cistuses or rock roses, a genus numbering many lovely shrubs, the majority of which are unsuitable for the average garden on account of their tenderness. Some will stand an average winter in a moderately cold climate, only succumbing to exceptionally severe winters, while a very few may be accounted truly hardy in the greater part of the United Kingdom. Among the last is Cistus laurifolius, which general agreement accounts a hardy shrub in all but the very coldest parts of the British Isles. It is well worth growing for the sake of its fine laurel-like leaves and its large white flowers, which show up so well against the dark green of the leaves. Its height is generally given as about 3ft., but the writer, on removing from a former garden, had to leave behind him a fine plant growing in poor, sandy, stony soil, and which was 6ft. high. It was with a pang of regret that it had to be left behind, but it was too large to transplant at the season in which removal had to take place. But C. laurifolius is easily raised from seeds, and soon attains a flowering size. Seeds may be sown under glass in spring. It may also be propagated by cuttings. C. laurifolius is a shrub, too, little met with, and is a really handsome flowering subject.—S. ARNOTT.

THE BUSY MAN'S PAGE

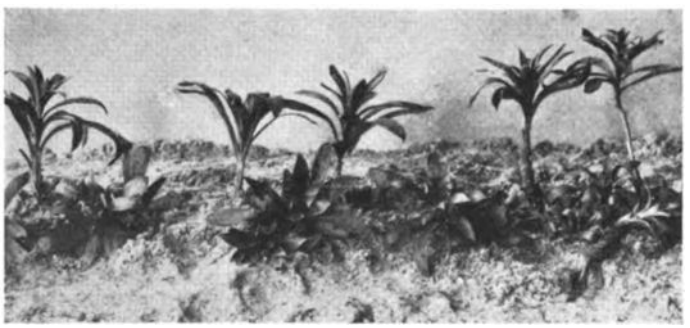
About Digging.

AS a rule, it is better when digging to use the left foot, but a great many people can do better work with their right foot, and to dig in comfort is the main thing. The spade should be thrust into the ground in a perpendicular position, the left hand being slid down the handle and the dislodged soil turned right over. The mistake made by so many beginners, and one which makes digging so back-breaking, is that they go on too long without a rest and a straightening of the back. As well, too, some people take too large a slice of soil at a time, and in this way add enormously to the heaviness of the work. When digging, it is an excellent plan to take a short rest every five minutes or so, during which care is taken to straighten the back and limbs.

Thinning Out Seedlings.

INSTEAD of leaving our seedlings—of any kind—to settle their own destiny under the principle of "survival of the fittest," it is far better to take in hand the shaping and making of the fruitful plant ourselves. Let us *select* the fittest and thereafter see that it survives to prove its fitness.

AN UNTHINNED ROW OF SEEDLINGS.
Note the crowded condition.



A ROW OF SEEDLINGS THINNED OUT.
The uprooted plants are lying on the ground.

When seeds of vegetables and annual flowers are sown, they do not all germinate alike, neither do the seedlings grow alike. Some show a very backward tendency in growth, others take on size rapidly; some are obviously weak and others strong. The aim of the cultivator should be to get rid of this weak and backward plant and retain the strong ones; and this can be done by a system of careful selection during the thinning-out process.

It is folly for the gardener to follow the practices of the farmer and thin out the plants by means of the hoe or the pulling out of handfuls of plants.

First, the seedlings should be allowed sufficient time to show their character, although this must not be prolonged until the plants begin to "draw." Go over the plants carefully and remove sufficient of them to allow each plant at least a square inch of space to itself, taking care that all those that remain are neither too weak in constitution nor too vigorous in growth. The cultivator should make a point of selecting only those seedlings for future growth which represent the average plants. Better flowering specimens are generally obtained by this method. Later on give a second thinning on the same principle of retaining these average plants.

Frost and Plants.

FEW people, when setting out plants, give sufficient attention to the positions selected. Subjects which are known to start very early, or to be of a delicate habit, must be placed in the right situations. It is difficult to get many people to believe that, generally speaking, the more open positions are the best for the tender subjects. On such a spot they do not try to start so early as they would in some corner, but there is an even more important consideration. As a rule, the sharpest frosts occur on a windless night and it does not freeze very hard unless there is something approaching a calm. Now, a calm state of the atmosphere may be brought about in an artificial way, and this is what often happens when a situation is much sheltered by buildings, walls, etc. A delicate plant which is put into what is felt to be a very snug corner may, when frost comes, be enveloped in stagnant air which rapidly falls to freezing point. Out in the open where there is more air stirring, the temperature may not fall so low by many degrees. For the same reason hollows are usually dangerous for plants that are not very hardy. A due south aspect is not by any means the best for plants which are somewhat delicate. A keen night is often followed by a sunny morning, and the warm rays pitching directly on the plants will do an enormous amount of harm to young shoots. A little observation in almost any garden will soon prove the truth of these statements. It is worth while making a few notes at this time of the year and seeing in which situations certain kinds of plants seem to do best. Frequently it is worth while moving a valued plant in order to get it into a more favourable position.

How to Treat Tall Room Plants.

ROOM plants, such as india-rubbers, cordylines, aralias, etc., will often grow very spindly and, at such times, most of the lower leaves fall away, leaving only a tuft of foliage at the top. An excellent way of treating such specimens is on the following lines: First of all, cut a small pot in half with an old saw. Then at about the middle of the stem of the plant make a long slanting cut upwards about half-way through. Hold the upper part of the plant if there seems a danger that it may topple over by its own weight. Now fill the two halves of the small pot with damp moss and place one on either side of the cut portion of the stem. Keep the moss moist, and in a month or so the upper portion of the plant will have sent out a quantity of roots into the material. When this has taken place the stem may be cut just below the pot so that the upper part of the plant is severed from the rest, and this may then be potted up separately. Very often, after this treatment, the lower portion of the specimen sends out shoots so that in the end there will be two presentable specimens instead of one that is very ungainly.

Mending a Cracked Bell Glass.

MANY people are inclined to discard a cracked bell glass, and at such times it is useful to know how to repair the article so that the damaged area will not extend. For the purpose secure some sodium silicate in syrup form, which is commonly used for the preserving of eggs; this can be bought from any chemist. Now get a large dish or tray which is somewhat larger than the bottom of the bell glass. In the middle of this place a lighted candle and pour water to the depth of about an inch on the tray. Place the bell glass over the candle and, without any delay, smear some of the sodium silicate all down the outside of the crack. Of course, as soon as all the air inside has been exhausted the candle goes out. The water prevents the inrush of any more air into the bell glass, in which there is something like a vacuum. Yet the pressure of the atmosphere remains the same on the outside, and, as a result, the sodium silicate is forced into the crack. Leave for about half an hour and then carefully remove the bell glass, standing it on one side. The crack becomes nearly invisible, and every day that passes the sodium silicate gets harder, until it is practically like glass. After about a week the bell glass may be used, and it will be found to be as good as new. This method not only repairs the crack but prevents it from extending.

Preparing Plants for the Summer Flower Beds.

IN March work will increase rapidly and there will not be much time to devote to detail work, and it is the detail work that counts for so much in the garden as elsewhere. Everyone who likes to have a fine display of flowers in the summer must provide many of the necessary plants during the previous autumn and winter months. If there is a good batch of rooting cuttings of zonal pelargoniums, heliotrope, fuchsias and marguerites, they should be examined closely now to ascertain whether any decaying leaves are likely to cause the stems to rot. Remove every decaying leaf by holding the cutting firmly with one hand while removing the offending leaf with the other, then the cutting will not be loosened in the soil and thus be retarded in its growth. The tops of the longest rooting cuttings will be available as cuttings also about mid-March, so it would be unwise to pinch them off and discard them now. The necessary cutting compost should be prepared now and kept in the potting-shed or in a box in the greenhouse. Pots, also, should be got ready now, washed and dried in readiness for the potting season, which will begin in earnest about the middle of February, when the autumn-struck tree carnations will be ready.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

A POPULAR FAVOURITE, GEUM MRS. BRADSHAW.

SWEET WILLIAMS ARE EVERYBODY'S FLOWERS.

Geums. THESE excellent hardy perennials, very showy either in beds to themselves or grown in a mixed border, have risen considerably in favour during the last ten years or so, and may be counted to succeed if plants are given moderately good soil mulched occasionally with rotted manure to conserve moisture. Geums are noted for the brilliant scarlet and orange flowers they yield practically from the middle of May until well on into autumn. Growing from 1ft. to 2ft. in height, they deserve a place in every garden. Young plants planted in April, from a sowing made last summer, will not be long in flowering. Division of roots in autumn or spring is another method of increasing the stock, but the better plan is to sow a pinch of seed every year, either in a bed in the open in May or June, or in a cold frame, as plants so produced give better results. Old plants, if left to themselves, are liable to damp off during winter. The town gardener is advised to bear in mind their worth.

Dielytra (The Lyre-Flower or Bleeding Heart). THIS, the dielytra, known under the generic name of dicentra, is a favourite in many gardens and, though ranking as a hardy herbaceous perennial, is best served if given a position on a warm and sheltered border. It commences to bloom in May, and remains in good condition for weeks onward. Dielytras like a rich soil, and once established are beautiful objects in a garden, both from a flowering and foliage point of view, in early summer. They appreciate mulchings in the way of old manure or leaf-soil from about the time the buds show. They are best increased by dividing the roots in spring. They make nice mid-row plants in a border, and should be planted 3ft. or 4ft. apart.

Tradescantia (Spiderwort). OF recent years amateurs have begun to turn their attention more to the tradescantias and to find in them plants, by the simple culture they entail, worthy of inclusion in their gardens. For long past they have been seen in country gardens, where, among old-fashioned plants they are given their rightful place. Their flag-like, narrow, green and purple veined leaves set off to the fullest advantage their flowers, which are lavishly borne. Tradescantias yield their blossoms from day to day almost, during their flowering season, which is from June onwards. They grow about 18ins. high, and will succeed well in either sun or shade in moderately good soil, Spring or autumn should see planting done, when also the clumps can be divided and replanted singly at 3ft. apart.

Sweet Williams. THIS old garden plant, sometimes treated as a hardy perennial, gives better results as a biennial. Of late years improvements have been effected in the strains, so that from a packet of seed sown out of doors in April or May, seedlings pricked off when large enough, one may have a stock of plants for blooming in the following year. Sweet williams will grow in any good soil enriched with a little decayed manure, and are best planted in groups or masses. They bloom from June onwards for several weeks. Another method of propagation is to take cuttings which appear at the base of plants in July and August, cutting them at a joint, and inserting in a bed of sandy soil in the open ground, shading as may be necessary for a few days. The variety illustrated is a fine strain known as Invincible, raised by Messrs. Webbs and notable for its size of bloom and diversity of colour.

Alstroemeria (Peruvian or Herb-Lily). THIS is a popular hardy plant which is used for massing in a border, and one which will be found to need but simple culture to ensure its success for years. Alstroemerias are tuberous-rooted subjects, thriving best in a rich, light and deep, well drained soil. A warm sunny position is essential, as, for example, a south border with a wall at the back. Clumps are best planted in March, when any division necessary ought to be made. Once established, however, they do not require to be moved very often. In selecting a site, the soil should be dug out to a depth of 3ft., and a good covering of brickbats placed at the base for drainage. They prefer a sandy soil, light in any case, to which should be added well rotted manure, cow dung for preference, along with which ought to be incorporated loam and leaf-mould. After making this firm, the tubers require to be planted 6ins. below the surface and 9ins. to 12ins. apart. During the winter it is advisable to spread over the surface a covering of leaves.

Unlike some other lilies they do not need staking, as they are strong enough to be independent of support. Amateurs who are prepared to give them treatment on these lines will have the satisfaction of having one of the most attractive plants, which will supply numerous blossoms from June to August.

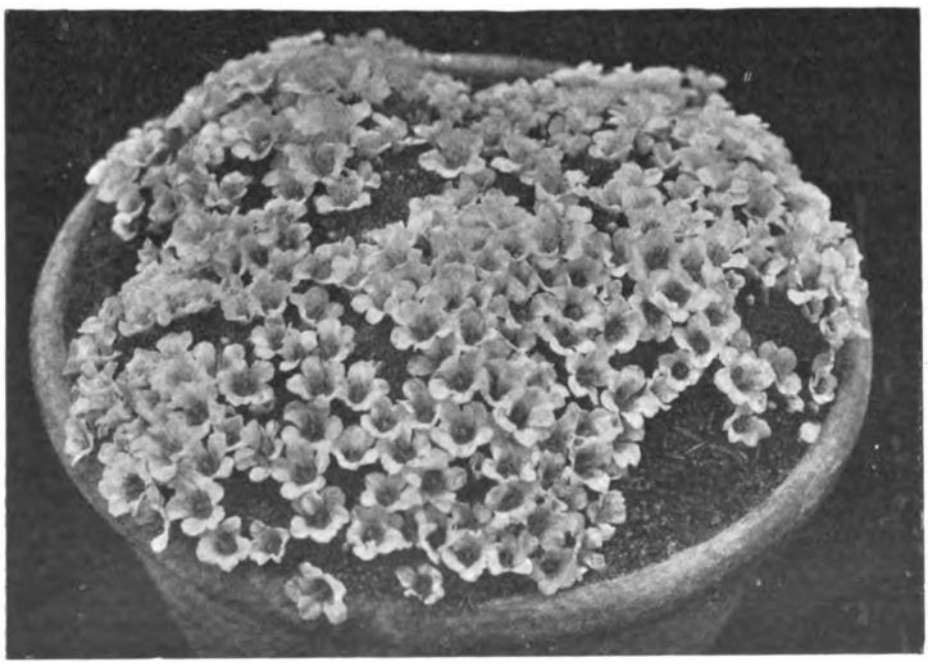
ROCK PLANTS FOR THE COLD HOUSE

Alpine house gardening is an enjoyable phase of rock gardening and many amateurs who possess a small cold greenhouse should make a start with a few of the more easily grown kinds described in this article. In further articles lists of subjects will be given suitable for the more advanced amateur, and also lists of bulbous plants which do well under this treatment.

THE choice of plants which may be used for this purpose is somewhat extensive, but in the following notes a selection of the most easily grown and most attractive kinds is given. The cultivation of alpine plants in pans is an attractive form of gardening and anyone with a small garden may grow many interesting plants in this manner. The amount of accommodation required is not extensive, while the majority of the most beautiful kinds are easy to grow. Once potted up in suitable soil, with perfect drainage, many of the saxifrages and androsaces, to mention only two families out of a great number, require little attention for two or three years. With the advantage of a small greenhouse without artificial heat in which to place the pans when the plants are coming into flower, their value is greatly enhanced, for then one can enjoy their full beauty unimpaired by unfavourable weather. During the rest of the year the plants may be grown with the pans plunged to the rim in ashes in a frame or on a sheltered border outside.

OXALIS ADENOPHYLLA IS A CHOICE ROCK PLANT FOR COLD-HOUSE TREATMENT.



SAXIFRAGA IRVINGII WITH ITS DELICATE PINK FLOWERS IS A GOOD ROCKFOIL FOR PAN CULTURE.

One of the most important families of spring-flowering plants is the genus saxifraga, or rockfoil. This contains many valuable kinds, one of the best and earliest being S. Burseriana in its various forms, with large white flowers borne on slender stalks above a cushion of glaucous spring foliage. Other white-flowered kinds are S. Petraschii, S. Sundermannii, S. Salomonii, S. marginata and S. Jenkinsiana, once known as S. Boydii alba. Yellow-flowered kinds are the lovely S. Boydii, S. apiculata, S. Haagei, S. Paulinæ and S. sancta. Among those having red flowers is the January flowering S. Grisebachii, S. Stribrnyi and S. Frederici-Augusti, while for making a charming show in pans there is nothing to excel the purple red oppositifolia. Of the latter there are several forms, including a good white one. All the above kinds open their flowers from January to March, and are followed by the crusted kinds, like S. cochlearis, S. lingulata and the handsome S. Cotyledon, with its pyramids of white or pink spotted flowers.

Cyclamen are charming plants very suitable for growing in pans and usually open their flowers in February, but remain attractive for weeks. There is C. ibericum, with its rosy purple flowers and faintly zoned leaves, and C. Coum, which differs from the other in having unspotted dark green leaves. After flowering they should be placed outside to complete their growth and the corms should then be well ripened off by exposure to the sun. One of the earliest plants to bloom is the beautiful Adonis amurensis, often in flower early in January. The large yellow flowers are succeeded by elegant foliage.

The early-flowering primulas include the Himalayan P. denticulata, with its dense heads of rosy or lilac purple flowers; P. rosea from the same region, with its pink flowers, and P. marginata, from the Maritime Alps, with its silvery margined leaves and pale lilac flowers in February. These early kinds are followed by numerous others later on in the season, one of the best known being P. auricula, with its mealy foliage and yellow flowers. With the exception of P. denticulata, these are all good perennials and may be grown on from year to year, but P. denticulata is best raised from seed every year.

The androsace family consists of mostly alpine plants growing at high elevations on the Alps of Europe, and on the Himalayas. While many are difficult to grow a few are amenable to pot culture and make charming little plants for the cold house. One of the prettiest is A. Laggeri, which comes from the Pyrenees, where in places it almost takes the place of turf in this country. In sandy peat it forms tufts of deep green foliage, covered in April with umbels of bright pink flowers. Also easily grown is A. sarmentosa from the Himalayas, with rosettes of silvery woolly leaves and bright rose coloured flowers. A. Chumbyi has smaller rosettes and brighter coloured blooms. These plants want loamy soil, with plenty of sand and broken limestone chips and are best propagated by means of offsets, which are produced in abundance. From the Falkland Islands we have a charming plant in Oxalis enneaphylla. This grows about 4ins. high, with glaucous leaves, having about nine leaflets each. From among these the

Digitized by Google

large, pure white flowers are produced in spring. A pink flowered kind, O. adenophylla, comes from the Andes of Peru, and differs chiefly in having two flowers on each stem. These plants prefer half shade.

The stork's bill family (erodium) contains several useful plants for our puprose, including the silvery-leaved, yellow-flowered E. chrysanthum, the white-flowered E. amanum and the pink-flowered E. petræum. Closely allied, and of neat compact habit is Geranium argenteum, about 6ins. high, with silvery leaves and pale purple flowers with deeper coloured veins. G. subcaulescens, also of compact habit, has large rosy purple flowers. All these like a sandy or stony soil, well drained.

Gentiana verna, one of the most beautiful of alpine flowers may be grown in pans, potted in sandy soil containing limestone chips, while G. acaulis may be lifted from the open border and potted up in heavy loam to flower in the cold house. An easily grown and attractive plant is the Pyrenean ramondia, R. pyrenaica, with leaves in rosettes close to the ground, and deep lilac flowers with an orange

THE DAINTY CYCLAMEN COUM SHOULD BE INCLUDED IN ANY SMALL COLLECTION.

THE FEBRUARY-FLOWERING PRIMULA MARGINATA, WITH ITS SILVERY EDGED LEAVES.

yellow centre. It should be potted up in fibrous soil and broken limestone, with the rosettes well above the rim of the pot. It does best in half shade.

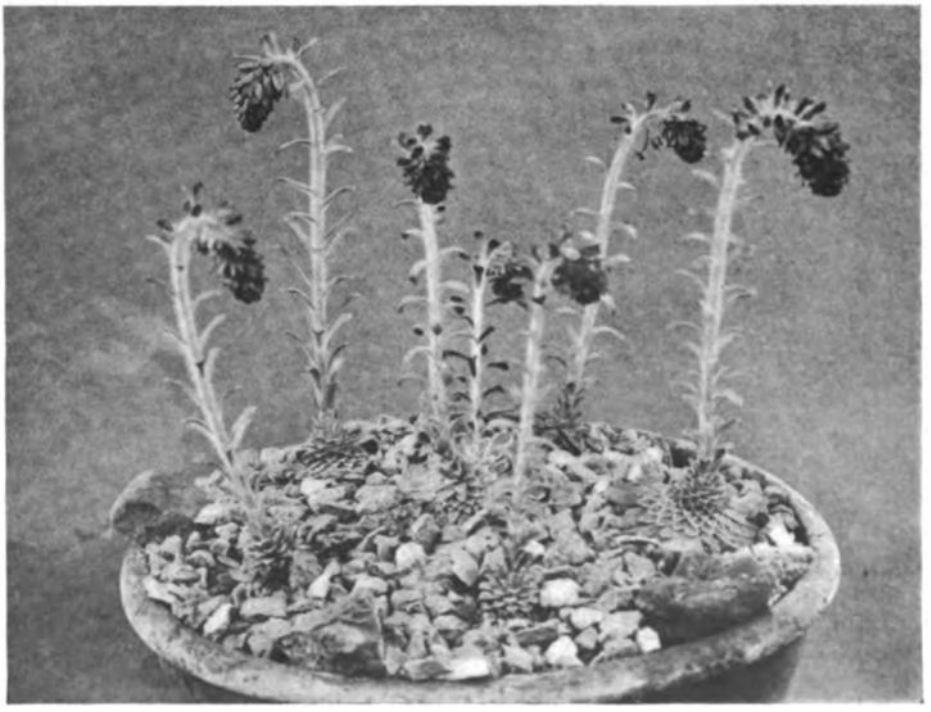
Other miscellaneous plants useful for this purpose are the achilleas, including A. ageratifolia, a dwarf plant with silvery leaves and pure white flowers; A. rupestris, with green foliage and white flowers; and A. Kellereri, a taller, handsome plant, with long silvery leaves and large white flowers. Shortia galacifolia from North Carolina, has white fringed, bell-like flowers. S. uniflora from Japan has large pale pink flowers early in spring. There are drabas of various kinds, also Morisia hypogæa with rich yellow flowers. Mountain avens (Dryas octopetala) is a useful plant with its evergreen foliage and large white flowers. Later on in the spring come the various kinds of dianthus, which are, with few exceptions, readily grown in gritty limestone soil. Soldanellas, too, may be grown in rich, moist, loamy soil containing plenty of leaf soil and sand. The above, and a selection of sempervivums and sedums would make a pleasing display during the spring months.

Although some of the alpine plants from higher elevations require special conditions and soil, a large number are easily accommodated and will flourish freely in gritty or well drained, porous soil. The size of the pans in which the plants are grown is immaterial, but the most convenient for general purposes are those 6ins. or 7ins. in diameter and about 4ins. or 5ins. deep. For saxifrages, sedums, androsaces and such like plants, the pans should be nearly half filled with broken crocks to secure good drainage. When in full growth and flowering, abundance of water is necessary for nearly all alpine plants; but at the same time anything in the way of stagnant moisture is injurious and should be avoided.

A Selection of Plants.

Achillea ageratifolia, A. Kellereri, A. rupestris, Adonis amurensis, Androsace Chumbyi, A. Laggeri, A. sarmentosa, Brodiæa uniflora, Cyclamen Coum, C. ibericum, Dianthus cæsius, D. neglectus, D. alpinus, Draba aizoides, D. imbricata, Dryas octopetala, Erodium amanum, E. chrysanthum, E. supracanum, Gentiana verna, G. acaulis, Geranium argenteum, G. cinereum, G. subcaulescens, Morisia hypogæa, Onosma tauricum, O. albo-roseum, Oxalis adenophylla, O. enneaphylla, Primula auricula, P. marginata, P. Juliæ, Ramondia pyrenaica, Saxifraga apiculata, S. Burseriana, S. Boydii, S. Petraschii, S. Haagei, S. marginata, S. lingulata, S. lantoscana, S. cochlearis, S. Cotyledon, S. longifolia, S. Grisebachii, S. Irvingii, S. oppositifolia, S. Faldonside, S. lilacina, S. Elizabethæ, Sedum spathulifolium, Sempervivum arachnoideum, Silene acaulis and Shortia galacifolia.

The following bulbous and tuberous-rooted plants are most effective when grown in pans. Narcissus cyclamineus, N. triandrus, N. Bulbocodium, Iris reticulata, I. Histrio, crocuses, snowdrops, Anemone apennina, scillas, and muscari. W. I.



A PAN OF SAXIFRAGA GRISEBACHII IS WORTH GROWING FOR ITS RED FLOWERS WHICH APPEAR IN JANUARY AND FEBRUARY.

THE FRUIT AND KITCHEN GARDEN

Early Potatoes on a South Border.

FEW things are more welcome in the garden than the new potatoes and to secure these at an early date is the aim of every grower. Of course, potatoes may be forced in frames, but excellent results are secured by growing them on a south border which is backed by a wall or fence. A few years ago the writer watched the digging of new potatoes at the end of April in such a position, and these had come to perfection during a season which had brought quite a lot of cold weather. To secure such a result it is important to employ an early variety of potato and also to start the sets as soon as possible. The trays or baskets containing the seed should be placed under the stage in a cool greenhouse or conservatory, care being taken to protect them from frost. Allow only one eye to develop, all the others being rubbed off. Meanwhile the position for planting may be prepared in the following manner. Throw the soil of the border out to the depth of about 3ft. Into the trench place a layer 2ft. deep of strawy manure, treading this well down. On the top of this add about a foot of light soil and, in this, the sets are planted at the depth of 3ins., 15ins. being allowed between each. The surface of the bed should be protected with some litter-like straw, fern, etc., and this should be forked over now and again to prevent its getting into a sodden state. Do not leave the litter long after the appearance of the plants or the stems will become drawn and weakly. At night, and during cold days, protection must be continued and this should take the form of mats, which must be supported just above the plants. A good way is to slant bean poles from the wall to the edge of the rows and then fix the protecting material to these.—S. LEONARD BASTIN.

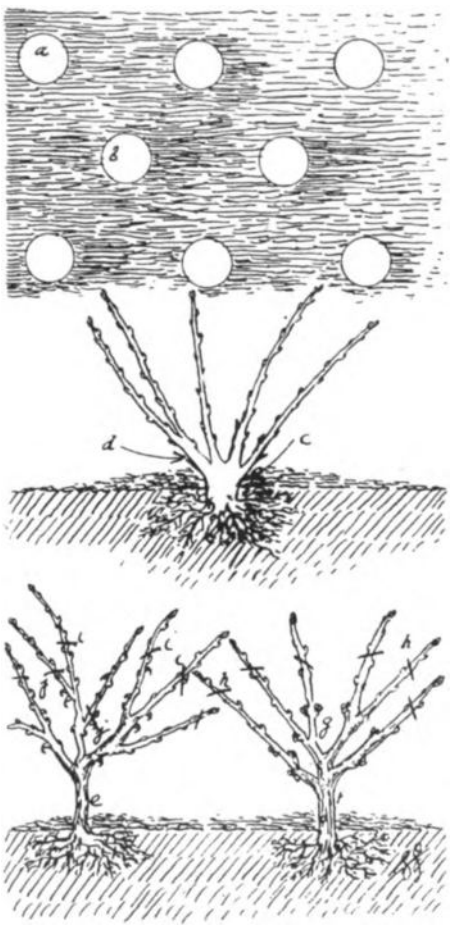
Winter Greens: Planning for Succession.

WE shall be in the throes of sowing seeds of vegetables very soon, and consideration will be given to winter greens, among other things. It is well to consider carefully our requirements in this direction and to make our plans accordingly. Winter green food is not the least useful to the householder, and it is wise to provide what will furnish a good supply for table use for the longest time. If we can make provision for a variety of winter greens commencing in October up to the end of April or early May, then we can face the autumn knowing what will be forthcoming. A small section of our ground, at least, should be reserved for autumn cabbage, and a pinch of seed of Hardy Green or Rosette Colewort should be sown in March; failing these, Christmas Drumhead cabbage, which is finding more favour every season, should be tried. Savoys like Drumhead or Green Curled Dwarf, and Brussels sprouts such as The Wroxton or Carter's Exhibition, will provide much useful food until well after Christmas. In the case of Brussels sprouts, however, it is well to bear in mind that as they need a long season of growth, seed should be sown as early in the year as convenient, in a frame or on a hot-bed, and the young plants transplanted with the least possible delay. Having regard to the usefulness of kale, and its long standing, no one should leave it out of his arrangements. There is a great variety to choose from; Asparagus, Thousand Headed, Jerusalem, Arctic Curled, Cottager's Kale, Russian Kale being among them. One which I have found to be most serviceable is Sutton's A 1, a type of Scotch kale, which provides an abundance of sprouts for March until practically summer, and are as nice at the finish as when the first basket was gathered.

Ground for Winter Greens.—It always pays to grow winter greens by themselves on well trenched or deeply dug and well manured ground, rather than plant them out between other crops. There is nothing gained in trying to achieve the best from two crops on ground where room is to only be found for one.—CLAREMONT.

Planting Bush Fruit Trees Now.

I ALWAYS advocate the planting of fruit trees in the autumn where everything is convenient for duly carrying out the work. But however much we may wish to do the work in the autumn circumstances will prevent us from doing so in some instances. In different parts of the country there is some



fruit tree planting still to be done. If the soil has not been trenched it should be before any trees are planted, even if the latter are not planted before the end of February. Where ground is trenched a lot of garden refuse can be buried provided it does not contain bits of sticks and roots of coarse weeds. Small or surface-rooting weeds may be so buried wholesale. Couch grass and convolvulus roots, particularly, should be cleared out of the soil. If the couch grass is buried deeply in mas. form it will rot, but not so if, practically, it is replanted just under the surface soil. The lily roots should not be buried, but burned or left on the surface where exposure will soon kill them. If plantations are formed the planting should be carried out as shown at *a* and *b*, to ensure every bush the maximum amount of space in which to grow. Red and white currants and gooseberries should be planted 5ft. apart, and black currants 6ft. The tree should be planted with 2ins. of stem buried as shown at *c*, and any pink coloured buds very low down, at *d*, should be preserved, as in due time they will grow and form fine branches. Gooseberries and red and white currants, respectively, should be planted as shown at *e* and *f*. The centre of each bush, *g*, should always be kept open, and the branch-pruning done as shown at *h*, *h* and *i*, *i*, *i*. If there are inside branches likely to grow and cause overcrowding, as shown at *j*, *j*, cut them out now. Well surface-mulch all fruit trees planted now, and if in very exposed positions stake them.—GEO. GARNER.

Completing the Pruning of Fruit Trees.

THE pruning of fruit trees means, to some people, simply the cutting away of practically all the young shoots that grew last summer. But pruning—judicious pruning—means a work that will help to balance future growths individually as well as improve the form of the tree. Instead of cutting back all young shoots, it may be of advantage to leave most of them—many their whole length, others being shortened by about one-third their entire length. Furthermore, in the case of some trees—those that have been neglected in past years—it may be advisable to cut out entirely several central branches to allow light and air to reach the buds and leaves of the ones retained, thus preventing the undue crowding of branches that one sees in nearly every garden where fruit trees are grown. In the case of trees trained to wires or on walls, there may be gaps to fill up with young wood; so, before you cut off a single shoot, closely examine the tree and ascertain whether any leading shoots must be retained their whole length, or nearly so, and, as a result, improve the specimen. Wall and espalier-wire space is too valuable to waste; every square foot should be covered with healthy branches in due course. When fairly large branches are sawn off, finish the work by paring the end of the limb smoothly with a sharp knife. If any grafting is to be done later on and grafts from certain trees are to be used, those cut off now and heeled in will furnish very suitable ones.—CHRISTCHURCH.

The Fruit Storeroom.

AT this season of the year there is a great scarcity of home-grown fruits. In many parts of the country hardy fruits were scarce at the harvesting time, and throughout the past few weeks great care has been taken of the rapidly diminishing stocks. At the present time we have to be extra careful, as ventilation is almost impossible when the weather is frosty or very wet and decay is rapid. All decaying specimens should be removed, but in doing this avoid touching the sound ones more than possibly can be helped. I have seen sound apples turned over and wiped dry on one day and black with decay a week afterwards. The stickiness is Nature's protection against decay, and when it is removed decay soon begins. The apples should not be subjected to a high temperature; one near to 45° Fahr., and even, will be suitable. Doors should not be left open more than is necessary for passing in and out again. Some amateurs' fruit stores are very primitive ones, but they are, nevertheless, very effective and serve their purpose. In the great majority of fruit store-rooms there is no artificial heat provided, nor planned ventilation. Where such is the case and frosty weather prevails, the apples should be stored under clean dry straw quite 1ft. deep. So treated, the fruits, if sound now, will remain so until April. Any medlars remaining in the storeroom should be gently moved to another layer of dry sand; they should not

Digitized by Google

be covered. Grapes in bottles of water will need close attention twice a week. When the water is changed preserve the charcoal, and to each bottle of fresh water add finely powdered charcoal in addition to the old lumps. Neatly cut out decaying berries.—G. G.

Leeks for Cooking.

LEEKS which are grown for kitchen use do not need the elaborate care and attention required by the white-necked monsters which adorn the exhibition boards. Seed of a good variety (see below) may be sown in February for autumn needs, and in March or April for winter needs; it may be germinated in heat, but thin sowings in a sunny frame give excellent results and avoid any extra work. A great point, in the early stages, is to keep the growth hardy and strong: a little manure may be spread in the bottom of boxes used for transplants or mixed with the compost of the frame, but this, after all, is not necessary. In spring, the ground intended for leeks may be manured and dug; quite good crops come from ordinary supplies of manure, but I agree that the grower can derive advantage from being a little more lavish than usual. If he intends feeding in late summer, however, then lavish manuring is waste. Plant the leeks when they are 9ins. high, in holes 6-8ins. deep, in rows 1ft. apart, the hole being made with a broom-handle, and no soil, except just a little to cover the roots, being filled in. Wide rows like these enable the grower to hoe up in early winter, thus adding 2ins. or 3ins. of blanch. Fowl manure is the best feeding in autumn. After growing leeks for cooking for thirty years, I always advocate a Scotch strain of Musselburgh; other good varieties which stand bad weather without deterioration, which crop well and give first-class results are Tulliebelton, Scotch Lyon, Champion, Ayton Castle and Royal Favourite—there is little to choose between them. I advise all readers to grow what they need, as the leeks sold for transplanting in May, June and July are—well, not so good as home-raised leeks.—CLYDESDALE.

The Earliest Cauliflowers from a Spring Sowing.

IF the amateur possesses a small greenhouse, moderately heated, he can bring on quite a lot of early vegetable plants. One kind that is well worth troubling with now is the early cauliflower. The plants from autumn-sown seeds must withstand the winter, either fully exposed or protected a little in a cold frame. In severe weather these plants often suffer a severe check and, as a result, the heads are small, often scraggy instead of being white, full and firm. Where there is not a batch of autumn-raised plants to depend upon, some should be raised at once under glass; and even if there is the former it is advisable to sow seeds in boxes to supplement the autumn stock of plants.

The cauliflower thrives best in a naturally moist soil which is well drained. It is while the plants are in their seedling stage that the most care must be taken of them, as they are liable to damp off wholesale. To avoid loss in this way the following hints should be noted. Use clean boxes, new; mix old chrysanthemum soil with a small proportion of fresh leaf-soil; water the compost in the box, allow it one hour to become drained, sow the seeds very thinly—about 1in. apart—cover them ½in. deep with dry soil, do not afterwards water from the top but by partly immersing the box. Transplant the resultant seedlings when the first rough leaf begins to form. Instead of just burying the roots make a hole deep enough to take the seedling to its seed leaves and carefully fill up the holes with dry fine soil; do not press any soil to the roots or stems with a dibbling stick. If these points are observed and great care taken in applying water, very fine sturdy little plants will be ready for planting in a bed in a cold frame by the middle of March, and in the open by the end of April.—HANTS.

Box-Raised Onions.

THE home-grown onion keeps for a longer time if the seedlings are raised early in the year than is the case when they are raised in the open border late in spring. The reason for this is that the bulbs are riper. Only small bulbs from spring-raised seeds will keep as well as the box-raised ones. If bulbs are required for exhibition, the seeds must be sown very early. Avoid old boxes in which fungus may be found. I whitewash the insides of my boxes with freshly slaked lime. Good old potting compost made from fibrous turves last summer will be an ideal medium in which to sow the onion seeds. The boxes should be quite 7ins. deep, and in the bottom of each one place a layer of well rotted manure. If fresh loam is used do not add much leaf-soil to it but a heavy sprinkling of builders' old mortar rubble. Now, for exhibition purposes some cultivators barely cover the onion seeds with soil. This is a mistake. I have seen many batches of seedlings just beginning to grow, and three out of five had twisted or curled stems. Result, bulbs with badly shaped necks, often the stems are flat instead of being round. Cover the seeds quite ½in. deep and sow them 1in. apart. Then the seedlings can remain in the seed boxes until the final planting-out time—about mid-April. They receive one check; if transplanted first in other boxes they receive two checks to growth. —CHRISTCHURCH.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Bulbs in the Rock Garden.

Miniature daffodils and other bulbous plants growing in the rock garden are apt to get badly splashed by the heavy spring rains, with the result that their delicate beauty is entirely spoilt. The best means of protecting them is by carpeting the ground with some low-growing evergreen plant, which will prevent the mud splashing upwards. Naturally, the plants we choose must not be too vigorous in growth, or they will rob the bulbs of their proper nourishment. Members of the thyme family are very useful for carpeting purposes, including T.T. azoricus, citriodorus, ericæfolius, and Serpyllum and its varieties. Other good plants to use are arenaria, saxifrages in variety, especially the mossy sorts, and the dwarfer evergreen sedums. Most of the plants mentioned above are flowering sorts, so they will provide colour in the rock garden when the bulbs are over; while some of the thymes have beautifully variegated silver or golden foliage.—B. D. S.

To Get Rid of Moles.

Moles often make their runs in cultivated ground, where they do damage to the roots, besides throwing up unsightly "mole-hills." Procure a small quantity of carbide of calcium, such as is sold to be used in bicycle lamps, etc. With a trowel remove the loose soil from a mole-hill and dig carefully down until you open the run. See that this is clear in either direction, then put into each open end of the run a few lumps of the carbide, cover with soil and smooth down. The moisture in the soil acts on the carbide and produces a gas which will kill any mole with which it comes in contact and ensure freedom from moles over a wide area. Should another mole-hill appear—which is very unlikely, as moles are very sensitive to smell—the same method should be repeated.—E. A.

A Hedge of Beauty.

When planting a hedge consideration should be given to its beauty. Three years ago I planted a hedge of Cotoneaster Simonsii and Berberis Darwinii alternately, and I think this is the most beautiful hedge I ever saw, and is much admired all the year round by all who see it. B. Darwinii is evergreen, with dark shining foliage, and clustered with rich orange flowers in April, followed by luscious blue berries (which, if wanted, make excellent wine). Cotoneaster Simonsii is a hardy shrub for autumn and winter effect. Covered with its beautiful tinted leaves in autumn, and brilliant orange red fruits or berries in winter, it cannot help but attract the eye. Both these shrubs can be obtained from any nurseryman at very little cost, and anyone following my plan will have a hedge of beauty in all seasons. —W. T. S.

A Non-Smelling Fertiliser for Indoor Plants.

Saltpetre is a most convenient and handy fertiliser to use for the majority of plants which are grown in the dwelling-house—such plants as aspidistras, palms, campanulas, geraniums, etc. The best method is first to water the plants thoroughly and, when the surplus water has drained off, dust the surface with as much saltpetre as will lie on a threepenny piece, afterwards giving a slight watering to dissolve the fertiliser and wash it into the compost. The above quantity is sufficient for a plant growing in an 8in. pot. Feeding of indoor plants should commence after the compost is full of roots and continued weekly during the growing season.—S. G.

Damping in Frames.

I do not know a better method to prevent damping in frames than the following: When matting or covering up for the night always leave a little air on by placing a piece of wood ½in. thick under each light, and allow the matting or sacking to hang well down over the frame so that the air in passing through is warmed, and no matter what kind of weather prevails no draughts can enter the frame.—J. H.

To Improve Potting Loam.

Keep some of your next load of loam for potting purposes in the chicken run and let the birds scratch it over freely. You will find the result in the finer blooms in the conservatory.—K. D.

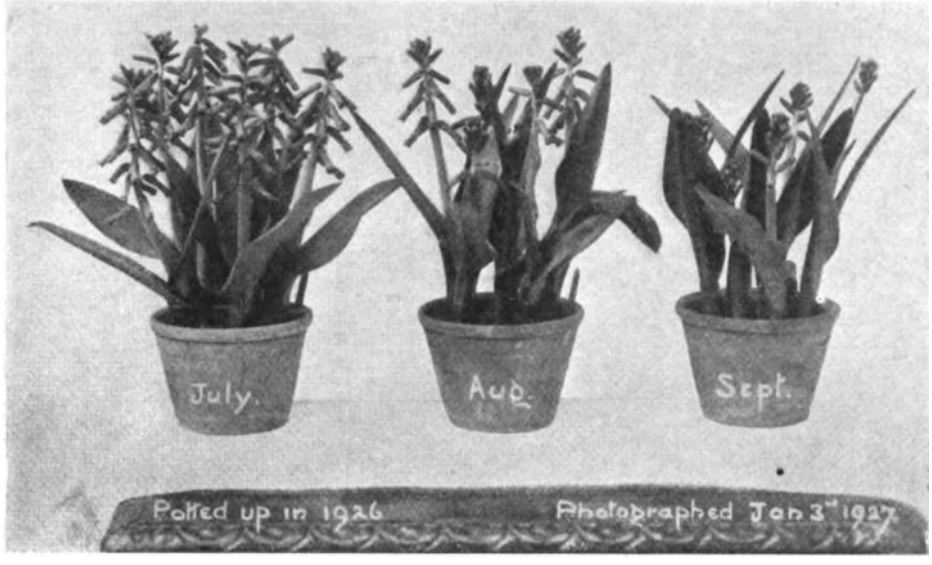
WHAT OUR READERS SAY

LACHENALIAS.

SIR,—Just about a year ago, in your issue of January 9th, 1926, there appeared a letter from the late Rev. Joseph Jacob referring to Lachenalia pendula and its early flowering characteristics; it was probably the last letter sent to the press by that distinguished horticulturist.

It seems to be opportune to make further reference to this plant just now, because at the moment and for some weeks past it has been giving a wealth of colour in "cold" greenhouses and protected frames at a time when colour is especially welcome; the sturdy spikes rising from robust, upstanding foliage, well furnished with long tubular bells of bright coral red, tipped at the lips with purple and green, are presenting a striking picture of outstanding beauty. I recently saw a very fine group which was in full bloom on December 14th, 1926, grown under absolutely cold house conditions, with no protection except against actual frost and illustrating to a marked degree the usefulness of the variety as an amateur's plant, though this may be equally claimed for the large range of beautiful lachenalia hybrids, most of which bloom somewhat later.



LACHENALIA PENDULA, A BEAUTIFUL EARLY FLOWERING PLANT FOR THE COLD GREENHOUSE.

By successional planting it can be had a long time in flower.

Another point in favour of L. pendula is that it may be used to bridge over quite a long period of colour famine as, by making, say, three plantings, each a month after the other, the flowering period may be extended from early December until the end of February; the three pots of which I send a photograph illustrate this feature rather well; they were planted in July, August and September and they reach their full flowering stage in December, January and February respectively; the flowering period of the general range of lachenalias is from the end of January to about the first week in April; it is therefore evident that by using the early-flowering L. pendula in the way suggested, the season during which these charming flowers can be enjoyed may be considerably lengthened and made to cover fully a third of the year—the months when brightly coloured flowers are of special value.—W. DAVENPORT.

FORCING RHUBARB.

SIR,—There are two points to bear in mind concerning the forcing of rhubarb out of doors. First, the flavour and quality are better than that forced indoors; and, secondly, outdoor forcing does not exhaust the plants like indoor forcing. The disadvantage is that one cannot obtain supplies so early. That is why it is necessary to do some indoor forcing. The method of forcing out of doors described by Mr. T. H. Everett in the issue for January 15th is an excellent one, producing good supplies finely flavoured and well coloured over a long period during spring. Most gardeners, however, like to obtain a little somewhat earlier than is possible outside. Where a greenhouse is not available there are other means. Personally, I always secure forced rhubarb by Christmas or soon after. Fortunately, I have a nice warm cellar under the house. About six or eight weeks before Christmas I put down some good forcing roots. The floor is covered with 2ins. or 3ins. of soil, the roots packed fairly closely on this and all spaces between them filled up well to the crowns. The roots then receive a moderate watering. A light framework is placed round them to carry a covering of clean straw over the top. The business is left there with no artificial heat or manure. As is well known, light must be excluded. Air is necessary. A particular point affecting the colouring and flavouring of this early rhubarb is watering. Moderate watering only should be practised. A little too much pales the sticks and weakens the flavour. Success in forcing rhubarb depends very much upon the variety and quality of the roots and upon the way these were treated previous to lifting. Rhubarb, like the black currant, is a very gross feeder. It will stand as much good farmyard manure as can be spared, and will yield all the better for liberal treatment in this direction while out in the open garden.—L. M. MARSHALL.

POTENTILLA NITIDA.

SIR,—In your issue of January 8th, Mr. W. Storrs Fox asks why I include this plant among those suitable for a beginner's rock garden, since it has flowered in his garden and those of his friends very seldom. It is true that this is one of many alpines which never yield in cultivation the lovely profusion of bloom in which they indulge in the mountains; but the flowers of nitida are so exceptionally beautiful that it is worth growing if we can obtain from it even a very moderate amount of bloom. And I do not think this is impossible. This plant affects dry, exposed, barren limestone places, making a woody tap-root which becomes eventually extraordinarily long and tough, and it sends out its prostrate branches over dry stony ground. If these conditions be imitated—full sun, very deep drainage, a poor limestony soil, and flat rocks between which it is wedged, it will, in most gardens, flower fairly satisfactorily, so far as my experience goes. I think it certainly objects to being fed, a rich soil causing it to go to leaf entirely. Is it possible that Mr. Fox has been treating it too well? I have found its ally, P. Clusianum, which sometimes passes for nitida, much more difficult to flower than the latter, and I had it for many years before I was able to see that its flowers are large and white. P. Clusianum is a larger plant than nitida, and the silvery leaves have a yellowish tint. How to make Clusianum flower with any regularity I am sure I don't know. Can any correspondent of THE GARDEN provide a hint?—R. LLOYD PRAEGER.

INSECTICIDES FOR EARLY SPRING USE.

SIR,—In early spring and during the summer months plants are generally attacked by sucking and biting insects, and to keep those pests in check spraying with efficient insecticides is necessary. There are now, fortunately, for the amateur grower a number of efficient insecticides on the market which can be safely used to combat the ravages of insect attack.

Sucking insects, such as green fly, cannot very well be controlled by using stomach poisons, all that the amateur requires is a good sticky substance which will corrode or clog up the breathing apertures of the insects. A good one I have found for this purpose is Cirengol, which can be obtained from any horticultural seedsman. There are any number of other proprietary brands, all, I am sure, equally good, and if a little soft soap be added it will make them even more effective in their work and much more economical. All these washes can be safely used against green fly attack on roses, fruit trees and many indoor plants if care is taken to use them in the proper proportions.

To check biting insect attack a good and useful remedy is to spray with Katakilla. It is very effective in destroying caterpillars of the magpie moth, gooseberry sawfly and many others which bite and gnaw the leaves of fruit trees and bushes. It is sold in powder form in handy little packets. A tablespoonful of the powder is sufficient to make two gallons of spraying material. The above-mentioned insecticides, although they are vegetable poisons, are safe to use, easy to handle and clean, no visible residue being left on the foliage, which is sometimes a deterrent when one wishes to spray against insect pests.—G. S.

THE CLIMBING GENTIAN.

SIR,—Among the little known Japanese plants—or at least unknown in British gardens—there is Crawfurdia trinervis, which Japanese call the Tsuru-rindo (climbing gentian). It is rather alpine in its habits, favouring the shade of trees in the mountains, where it climbs on dwarfer-growing plants or creeps on the ground. In the late summer the gentian-like flowers make their appearance. Its leaves are opposite, ovate-lanceolate, entire, pointed at the tip, and have three principal nerves, hence the specific name. The leaves on the main stem are 4ins. in length, while the leaves on the lateral shoots which form on a really vigorous

Digitized by Google

plant, are one-third or more smaller. The flowers are carried on the lateral shoots as well as on the main stem. The corolla is bell-shaped, with five lobes, pale reddish purple in colour. Before the corolla withers the bright purplish scarlet fruit appears, as with other gentians. It is a beautiful plant and somewhat of a curiosity. It does not ask for any particular treatment, but will respond to the same treatment as meted out to other gentians. I saw several plants growing on sunny mountain slopes associated with Swertia japonica and Parnassia palustris, but these were poor compared with those growing in half shade. This is one of the loveliest plants in our tiny island, Shodoshima, which is situated about sixty miles south-west of Kobe.—K. YASHIRODA, *Kagawaken, Japan.*

[If any of our readers are growing this plant, we would be interested to hear their opinion of its behaviour in the gardens at home.—ED.]

HOW TO CATCH MOLES.

SIR,—"A. T. J.'s" notes in THE GARDEN of January 8th are good and practical, but the "secrets" of the mole catcher, which I would rather call the useful knowledge acquired after years of careful study of the habits of this interesting little animal, are not "humbug" by any means—one often finds that a trap has been filled with soil and that the mole has passed round or underneath it and that this is repeated time after time when the trap has been cleared and reset. When this happens, do not move the trap, but set a spring pincher trap on each side of it in the samerun. I have always found this effective.—W. A. WATTS.

COLOUR IN THE SMALL GREENHOUSE

SMALL COST. LITTLE TROUBLE. CERTAIN SUCCESS.

Now is the time to make a selection of annuals to provide a bright summer display in the greenhouse

THE average amateur's greenhouse is usually a comparatively small structure, and in it the amateur is obliged to grow a collection of various plants. A few tomato plants are often grown together with foliage and flowering plants. The fairly high temperature required the latter plants during the early stages of growth is apt to spoil the tomatoes to some extent. However, the difficulty may be overcome by growing some of the following beautiful half-hardy and hardy annuals as well as other plants. These require only moderate heat to germinate, and, once in pots, may be grown on in the same temperature as the tomatoes. The large pots or boxes containing the tomatoes may be kept at the back of the staging and the flowering plants in front. The fact that the foliage of the former shades the latter will not seriously affect their growth. On the contrary, in certain cases this will be an advantage. The fuel shortage during recent months may also have caused some spring and early summer plants to be lost. Therefore, I suggest a selection from the following plants, all of which I have grown beneath—or, at any rate, in the same house as—tomatoes, with success: Browallia, half-hardy annual, is a pretty plant with delicate bright blue flowers and dark green foliage. Balsams, too, are useful, and the camellia-flowered sorts are equal in beauty to many a rare greenhouse plant. Brachycome—the Swan River Daisy—is splendid in pots. Last summer certain professional gardeners came to "crab" some plants the writer had produced, but forgot their mission on viewing these plants grown in pots. B. iberidifolia is blue in colour, but the seed may be obtained of the white, red and other coloured varieties. In shape the flowers resemble cinerarias. Phlox Drummondii is also useful in pots, and the white variety is very choice and strongly scented. The smaller sorts—compacta—grow about 6ins. high and have their special uses. Alonsoas, particularly the variety Mutisii, which is chamois pink in colour, are worth growing. Dimorphotheca, in spite of its name, is a good subject for this work. The everyday name for the plant is Star of the Veldt—the flowers are like dainty marguerites—and the plant grows about 14–15ins. high; the orange variety is, perhaps, best known, although there are now many fine lemon yellow sorts with a deeper central eye. Nemesias, grown well, are also useful pot plants. The various asters, treated with care, will grow well in pots, but, of course, can scarcely be expected to grow beneath tomatoes. Nemophila insignis, the well known blue-flowered annual, will grow in pots, and is "content to fill a little space." Viscaria, another annual, best known in its brilliant crimson form, serves the same purpose. Mignonette may also be grown—in fact, often is—for its scent, although amateurs may find it a difficult subject to get established. This list is by no means complete, but all the above have been tried, and sceptical friends of the writer have been surprised with what success these half-hardy and hardy annuals may be grown in pots.

Some care is needed in their culture. A little feeding, careful watering and the removal of all faded leaves and blooms will cause the plants to bloom for quite a reasonable length of time. Boxes 3ins. to 4ins. deep may be used in which to sow the seed. The soil must be fairly light and rich. Add a good sprinkling of sand and some wood ash to make it porous and sweet, and make sure that there is good drainage. Sow very thinly and barely cover the small seed. A sheet of glass covered with brown paper assists germination. Admit air gradually by tilting the glass a little as the seedlings appear. When growing keep the boxes close to greenhouse glass to promote sturdy growth. When large enough to handle, pot the plants into thumb pots or several in one larger pot. For the plants already mentioned 5ins. or 6ins. make good sizes in which plants are to flower. Those who have just acquired a greenhouse will find these plants useful for decorating it in early summer.

Other very suitable plants to grow in a general collection include begonias. There are both tuberous and fibrous rooted varieties. The tuberous begonias may be had in a wonderful range of colour. These are started into growth by being placed upon leaf-mould (I use fibre as used for bulbs) and potted on later. For making a brave show beneath tomatoes they have no equal. The plants enjoy the shade provided by the leaves of the tomatoes, and tubers capable of yielding immense crops of bloom may be had quite cheaply. Last summer I had a wonderful show by just gently pressing the rooted tubers into good bulb fibre. The fibrous rooted begonias are best purchased as plants, two of which will provide plenty of cuttings to form plants for subsequent display. Another useful plant is Campanula isophylla and the white variety alba. These are useful in baskets or to drape the edge of staging. All the seeds and plants mentioned may be obtained from advertisers in these pages, and from their lists other varieties may be chosen.

The seeds should be purchased now. However, those already given will prove successful if reasonable care and thought be given to their culture. If these instructions, together with the golden rule of admitting air when conditions are favourable, be followed, success is certain.

T. H. HEAPS.

BROWALLIA WITH ITS BRIGHT BLUE FLOWERS IS A FINE HALF-HARDY ANNUAL FOR THE GREENHOUSE.

DROOPING CAMPANULAS MAKE FINE DECORATION IN THE AMATEUR'S GREENHOUSE.

FOR SCOTTISH GARDENS

Notes Practical and Critical, Specially Written for Amateurs

JANUARY is probably the dullest month in the calendar for the amateur gardener in Scotland. The weather conditions are seldom conducive to outdoor operations, and the days are far too short to permit of indulgence in horticultural pursuits. The work has to be done in the evenings or on a Saturday afternoon when the state of the weather and the soil are suitable. In a normal season the difference in the climate between the north and south may be reasonably measured by time varying from two to three weeks, and, in view of the increasing tendency of sharp frost in late spring and early summer and the resultant injury to vegetation, caution should be observed.

Treatment of the Soil.

There are, however, certain operations that should be undertaken at the earliest opportunity, and the most important is the preparation of the soil. In these days of popularity and progress in the gardening world it is surprising to find that winter digging and deep cultivation are not practised by amateurs to the extent that one might expect. In my journeyings I come across many examples of gardens that are neglected in what may be termed the off season—that is, the interval extending from the end of autumn until the beginning of spring. There the withered remains of the previous season's crop are usually left in occupation until March, when the fair-weather, or half-yearly, gardener begins to waken up again and indulges in digging operations which, to all intents and purposes, consist of scratching the surface with a spade or fork.

To restrict operations in this way is poor gardening and offers little prospect of satisfaction or success. How different are the ways of the reflecting amateur who acknowledges the beneficial effects of early and deep digging, especially if the ground is heavy. Experience and common sense have taught him that the more thorough he is in his methods of treatment the sooner will he overcome the difficulties that are inherent to soil and situation. When the ground is dug to the depth of a couple of spades and left rough on the surface over the winter it reaches a state of friability that accelerates the germination of seeds and the rooting of plants. It also promotes a healthy rooting system, as the conditions enable the roots to forage in the lower strata there to find the coolness, moisture and nutriment that are essential to plant life. "Early, deep and thorough" should be the motto of the amateur in regard to soil preparation.

Sprouting Seed Potatoes.

As the question of the potato crop demands consideration at this season, it is most desirable that gardeners and allotment holders should recognise the importance of boxing and sprouting the seed tubers. The practice is generally followed by growers of early varieties, whose experience has proved that the yield is materially increased by that treatment, while growth is more uniform and vigorous and the period of maturity is accelerated. Hitherto the boxing system has not been adopted to any extent in the planting of main-crop, or late, potatoes, the reason being that the advantages were not so apparent in tubers requiring a longer period of growth. Recent experiments, however, have shown quite contrary results. At the trials conducted during the past four years by the North of Scotland College at Aberdeen the discovery has been made that a crop of Golden Wonder may be increased in weight to the extent of 25 per cent. simply by boxing the seed. This is welcome news, as the russet skin variety has a poor cropping reputation. Its popularity as a main-crop potato has undoubtedly suffered on that account, for Golden Wonder cannot be surpassed by any other potato in respect of its superior cooking and late keeping qualities. Shallow boxes or wooden trays are the most suitable receptacles for sprouting the tubers, and as seed is now available no time should be lost in procuring supplies. Whole seeds about the size of a hen's egg are the best, and after arranging them in rows, store the boxes in a frost-proof outhouse or shed.

Sowing Leeks and Onions.

Leeks and onions reached an exceptionally high standard of excellence in 1926. At most of the autumn shows they formed the prominent feature of the vegetable section and generally exceeded all previous records in respect of the number of entries, quality, and keenness of competition. One of the secrets of success is heat, either in the form of a warm greenhouse or hot-bed, and during the next few weeks the finest strains of seed should be sown thinly in boxes of rich, fine soil. A leading firm of seedsmen in Scotland specifies the last week in the month as the period for sowing leeks, but a few days' delay can hardly influence the ultimate results one way or another. Some of our most enthusiastic growers are to be found in the mining districts of Scotland, and in some parts the first week of February is recognised as the time for sowing both onions and leeks. When the plants are large enough to handle they should be thinned out or transferred to deeper boxes. An alternative method is to transplant each leek into a 3in. pot, while some growers prefer raising their leeks from the very beginning in pots by sowing three seeds in the centre and afterwards removing all the plants that come up except the strongest specimen, and thus avoid the check which follows root disturbance.
—ST. MUNGO.

THE CULTURE OF PANSIES AND VIOLAS

THESE useful flowers can be successfully grown in any district if the soil is well prepared some time previous to planting out and if a liberal quantity of farmyard manure is used. They probably succeed a little better in northern districts than in the south, but the satisfactory results achieved by southern growers during the last few years have proved that pansy and viola culture need not be confined to Scotland, the north of England and the Midlands.

An open site, not exposed too much to the scorching heat of summer, suits them best. A high wall that protects the plants from the mid-day sunshine, trees that afford shade but which do not overhang the plants, or the shelter of a shrubbery can be used to provide semi-shaded quarters, and if such conditions do not present themselves, temporary erections during the hottest months of the year can be devised. Low-lying situations, where the soil is apt to become waterlogged or sour, should be avoided, and under such conditions it is wise to raise the beds 3ins. or 4ins. from the ground. The plants are hardy and will withstand a fair amount of frost—in fact, many varieties will survive an average winter unprotected in the open garden, if the plants are vigorous and sturdy in the autumn. Old plants should be divided and this can be done during a mild spell in winter or the operation can be left until early spring. Plants grown on the two-year system give a profusion of early bloom during April and early May. When replanting or dividing old plants a careful watch should be kept for slugs, which are usually found under cover of the tufty growths. It is a good plan to introduce some new, clean soil and pack this round the collar of the plant.

Preparation of the Soil.

Soil preparation should be begun without delay. The earlier this can be completed the better, so that the soil has sufficient time to settle down before planting-out time comes round. Dig or fork over the soil to a depth of at least a foot and incorporate plenty of well rotted manure. Cow manure is preferable for light or medium soils. Use strawy horse litter for heavy soils. Leaf-mould and soft surface weeds can be buried in the lower spit. A liberal use of animal or green manure is essential because of the great need for a plentiful supply of moisture during the long growing period. Mulching is a necessary operation later, when the surface roots are in need of protection from the scorching sun heat. Bone-meal, superphosphate and wood ash may also be dug in or mixed in the top spit. The surface should be left rough for a few weeks during the winter months, and if the soil is deficient in lime a sprinkling should be given on the surface in February. As the soil settles down and as planting-out time draws near the sites should be marked out and the plot raked down to a fine tilth. Allow at least nine inches between the plants, more if space will allow.

Planting Out.

Cuttings which are being propagated in cold frames or which were inserted in early autumn in the open need a little supervision during the winter months. After frosts some of them may be thrust out of the ground. These should be pressed into the soil and a sprinkling of sand added to encourage further root action. Remove any leaves that have rotted or withered, or the cuttings are apt to damp off. Do not keep the frame lights too close when once root action has begun. On all favourable occasions plenty of ventilation should be given and the plants gradually hardened off until the frame lights can be entirely removed. By the middle of March the cuttings should be sufficiently rooted and hardened for planting out to commence.

Choose a favourable day for this. The soil should be on the moist side but not sticky. Remove the rooted cuttings from the frames by means of a hand fork or trowel and plant them firmly. Plants purchased from reliable nurserymen are already hardened off, and these may be planted in their permanent quarters when received. If they are not well rooted add a little sand when planting out.

During the blooming period all faded flowers and seed vessels should be removed regularly, and the plants need occasional trimmings after each crop of bloom when the growths become long and ungainly. In very dry periods watering is necessary. This should be done in the evening and a good soaking once or twice a week is generally sufficient. A surface mulch is beneficial in helping to conserve moisture. Keep the hoe at work among the plants, and this will prevent loss of moisture as well as checking the growth of surface weeds.—NORMAN LAMBERT.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Checking Carrot Fly.

Could you kindly answer the following: What is the best cure for carrot fly? I have not been able to grow good carrots for some years.—J. A., Porlock Weir, Somerset.

Carrot fly is an exceedingly difficult pest to eradicate once it gets a thorough hold. We should advise you to prepare a bed with very sandy soil in early spring, and sow seeds in this bed, the soil of which is made very firm. The seed should be sown fairly thinly, and when the seedlings are about 2ins. high they should then be thinned out, care being taken to press the thumb over the hole from which the seedling has been taken. The soil should be kept perfectly firm and even hard round the young plants. This prevents the entrance of the carrot fly. When young carrots are being lifted from the beds, take the same precaution of filling up the spaces which are left, and make the soil perfectly firm.

Manuring of Roses.

I have had my roses limed with a view to checking a certain amount of fungoid disease. Last season they had no farmyard manure, only one dressing of artificial. Can I give them farmyard manure at pruning time?—F. T., Barrowby, Grantham.

We should suggest that when pruning the roses at the beginning of March, you should apply a dressing of strawy manure, which will act as a protective surface mulch, and also will benefit the soil and stimulate new growth of the rose bushes. You will also find that the surface mulch will prevent the soil—in the event of a very dry summer—from drying out and thus to a certain extent injuring the surface roots of the bushes.

Alpines for a Cold House.

Would you kindly send me a short list (about eight) rock plants to grow inside a greenhouse, without heat. I have converted a summer-house into a greenhouse, but it still has a wooden top and back, but glass sides and front, facing east. Would you also send me the name of a creeper I could have growing up the back, inside, forming a background for my miniature rockery.—C. P., Eltham.

We should suggest the following list of rock plants to grow inside a cool house: Saxifraga Grisebachii, S. lilacina, Dryas octopetala, Androsace sarmentosa, A. villosa, a few dwarf irises, such as I. reticulata or I. Wedgwood Blue, Primula chionantha, Campanula Allionii and C. Zoysii.

A most attractive climber for growing up the walls of your greenhouse would be Streptosolen Jamesonii or Eccremocarpus scaber. The climber, however, should not be allowed to take away light from the rock plants, otherwise you will find there will be a dearth of flower.

Pruning Laurels and Box.

(1) We have a box hedge which has grown tall and straggly and has died in parts. Would it improve it to cut it down now—to within 1ft. to 2ft. of the ground? Or would shoots from it strike now—to fill up the gaps? If that would not do, would it answer to move some box shrubs which we have in the garden to make up the hedge?

(2) Is the present the time for cutting down laurels? We have some near the house which have grown too tall. We should like them about half the height and to shoot out from the bottom.—A. M., Boswells, Chelmsfrod.

Most of the box plants would die if cut down hard now. April is the best time to hard prune box bushes. The box shoots would not grow if put in to fill up the gaps. Cuttings of box can only be successfully rooted under glass. The best procedure would be to cut out the dead wood now and move the plants at once very carefully to fill up the worst gaps from another part of the garden, then, about the middle of April, cut down the old bushes.

With regard to the laurels, these should be cut down about the middle of April. New shoots grow freely from the base of laurel stumps.

Climbers for South and North Walls.

I would be much obliged for your advice on the following points: (1) South wall 72ft. long with border 30ins. wide. I want to plant this with climbers which will cover the wall without projecting too much and leave enough room for a few herbaceous plants in front of them. The essential point is that the wall may look well for as long as possible, need a minimum of attention and give breathing space to a few herbaceous plants. (2) North wall 72ft. long: I want to treat this wall in a similar fashion to the south wall as far as this is possible. Please state the number of climbers and plants I will require for each wall.—W. F., Swindon.

We suggest the following climbers for your walls:

For South Wall: Ceanothus rigidus; C. dentatus, Pyracantha angustifolia, Myrtus tarentina, Chimonanthus fragrans, Pyrus japonica, Escallonia langleyensis, E. exoniensis, Osmanthus Delavayi; Rose Richmond, R. Climbing Mme. Abel Chatenay, Jasminum officinale.

For North Wall.—Hydrangea petiolaris (scandens), Jasminum nudiflorum, Rose Gloire de Dijon, R. Reine Olga de Wurtemberg, Clematis Jackmannii, C. Flammula, Lonicera Halliana, L. serotina, Forsythia suspensa, Clematis Lady Northcliffe, C. Henryi.

Twelve climbers are required for each wall, and the average distance should be about 6ft. apart.

Calcium Carbide as a Soil Fumigant.

Could you tell me if spent carbide of calcium (the waste from an acetylene plant) is an effective substitute for lime; or, if not, if it is any use as a dressing for beds, fruit trees or lawns? The soil is red clay.—L. R., Monmouthshire.

Carbide of calcium will not take the place of lime. It can be used in a ground state at the rate of 4 oz. per square yard as a soil fumigant. It should be mixed with the soil at least 6ins. below the surface. Nearly all insect pests will leave the soil where the carbide is buried. Restrict it to the vegetable quarters.

Woodlice in a Vinery.

Could you please inform me as to the best method of killing woodlice in a vinery which is badly infested with them?—W. A. W., Morpeth.

Lightly fork into the top 2ins. of soil round the sides of the border—especially near the walls—3 ozs. of Vaporite per square yard. This will result in the wood lice leaving the part where the Vaporite is used. In a convenient part of the border or other portion of the floor put down several loose boards with some bran and quite dry soil between each pair of boards. In this way you should be able to clear out all the woodlice. Empty them as caught into boiling water.

Zenobia pulverulenta.

I am much charmed with that beautiful shrub (shown in THE GARDEN, *December 11th, 1926) Zenobia pulverulenta. Will you kindly let me know if it would be suitable where I live?—F. A., Highbury.*

We should think that zenobia would grow quite successfully with you. It likes a fairly peaty soil or a light, loamy one in which well decayed leaves have been incorporated. Give it a fairly sheltered position until it becomes established. Its ordinary flowering period is June and July, but it can easily be forced in the greenhouse during the winter months.

Kainit for Vegetables.

I found my chalk soil benefited from a dressing of kainit given last winter when the ground was dug. Much of the ground is at present occupied with green stuff—sprouts, savoys, kale and spring broccoli. May I ask if the kainit would harm the growing crops if sprinkled between the rows? Would it be better to wait until the crops are cleared? I understand that kainit should always be applied in the winter months.—E. S., Sutton.

We should certainly suggest that before applying kainit all the root crops should be cleared from the ground, so that you will have an entirely free hand at the time of application. On the whole it is a much better plan than sprinkling the material between the roots, as there is less likelihood of damage to the plants.

Propagation of Privet.

Will you kindly advise me as to the best method of rooting privet (golden and common)?—R. A. P., Gloucester.

To root green and golden privet make cuttings of growth 1ft. to 15ins. long and insert at once in a border of selected sandy soil outside. Select from healthy young wood and have just a thin heel of old wood at the base of the cutting.

Digitized by Google

Culture of Tigridias and the Scarborough Lily.

Will you kindly inform me as to the proper cultivation of tigridia bulbs? I have been disappointed in them these last two years since I first tried them. I planted them outside at the end of March in fairly heavy soil, but only one or two have attained the flowering stage. Will they succeed in a window-box? Any information as to soil, position and watering will be appreciated. Also what soil does the Vallota (Scarborough lily) require, and will it succeed out of doors?—J. D. C., Cardiganshire.

Tigridias should grow and flower freely outdoors when planted during March, but they require a warm position at the foot of a warm wall, and fairly light, well drained soil. If your soil is heavy, it should be lightened by the addition of sand or other gritty material, raising the bed above the ground level. In the south they should do well in a bed in the open provided the soil is warm and well drained. They should succeed perfectly in a window-box in a sunny situation, and will grow freely in any good potting soil, a medium loam being best, using three parts of loam and one of leaf-soil and sand. When the growth dies down during the autumn, you should lift the bulbs and store them in dry sand for the winter.

Vallota (Scarborough lily) will not succeed outdoors, but requires a cool greenhouse or a window; in fact, this plant is generally seen at its best in cottage windows. It succeeds in a good medium loam, with sufficient sand or old mortar rubble to keep the whole open and porous. When starting with dry bulbs very careful watering is necessary until they have made fresh roots and have started to grow. Although they may be kept drier at the root during the winter, they should never be dried off altogether, and when doing well should not be disturbed at the root.

Propagating Begonias.

I shall be glad if you will inform me how to increase my stock of Begonia Gloire de Lorraine and B. semperflorens. The former I am told is best increased by leaf cuttings. If so, how are these taken; has a part of the main stem to be taken with the cutting, or just the leaf stem, and when is the best time to take them? Again, have the old plants to be dried off after flowering. Is B. semperflorens treated in the same way? Also, when looking at some of my begonia tubers, which are still in their pots dried off under the staging of the greenhouse, I found that about half of my tubers were either rotten or like bits of dry, rotten wood and easily snapped in two. Have these been in too great a heat, do you think? —A. A., Northumberland.

Both your begonias may be increased by cuttings in spring. These may be obtained by placing the old plants in a little heat to start them. Take off the cuttings when about 3ins. long close to the base of the plant, and use a mixture of sand and leaf-soil. Place in bottom heat, when they will soon root, and if potted up and grown on will flower the same year. You have probably let your plants get too dry, which accounts for their being dead. B. semperflorens should not be dried off entirely.

VEGETABLES in SEASON all the YEAR ROUND

A TIMETABLE FOR EVERY MONTH OF THE YEAR.

THE following article has been prompted by the Editorial note entitled "The Gardener's Log-Book," on page 691 of THE GARDEN dated December 4th, 1926. For years past it has been my custom to keep just such a record as there suggested. The outcome of these records has led to various articles on seed germination, etc., and the present one is another outcome, the original of which was compiled some years ago, based on experience gained in various counties, mostly in the Midlands.

Without entering into unnecessary details, it may be of assistance to readers to know just what easily cultivated outdoor vegetables may be had in season each month of the year. In the subjoined tables, or monthly calendar, the dates of sowing and periods of production are, where considered necessary, clearly indicated. With few exceptions outdoor sowings only are referred to, so as to legislate for gardens without either greenhouse or frames. Exceptions are marked with an asterisk, which simply means that seeds sown at the dates mentioned need gentle heat to start them. Where no such gentle heat is available the only alternative is for growers to purchase seedlings elsewhere. It is to be noted that in the case of cauliflowers and broccoli, the season at which these vegetables turn in, when sown out of doors, depends upon the nature of the seed sown; thus, all the broccoli named are sown at the same time, either the very end of March or early in April, while cauliflowers are sown either at the end of September (for May, June and July consumption) or early in April (for August and September use). Winter saladings and herbs, like parsley and mint, can be successfully produced only where heat is available, and a special note in regard to them is appended. Here, then, are the monthly lists or tables referred to above.

JANUARY.

Broccoli (April-sown Early White), Brussels sprouts (April and May sowings), cabbages (May-sown late varieties), celery (May-sown red varieties), coleworts, or collards (May-sown Rosette and Hardy Green), Couve tronchuda, or Portugal cabbage (May-sown), garden swedes (May and June sown), kales (Cottager's, Sutton's A 1 and Drumhead, all May-sown), leeks (May-sown), parsnips (March-sown, to be lifted next month), savoys (May-sown late varieties), seakale spinach (July-sown, stands frost well till end of this month), white sprouting broccoli (May-sown).

Other Vegetables in Store.—Beet (May-sown, lifted in October), carrots (May-sown late varieties, June-sown intermediates and July-sown early varieties), onions (March-sown), potatoes, Jerusalem artichokes (planted in March and lifted in October or early November), turnips (August-sown winter varieties, lifted in November), vegetable marrows (May-sown, gathered before skin becomes too hard to yield to light pressure of thumb-nail and well dried off before storing).

FEBRUARY.

Broccoli (April-sown Snow White), Brussels sprouts (May-sown, finish), cabbages and coleworts (same as for January), celery (same as for January, finish), Couve tronchuda (June-sown), garden swedes (lift and store), kales (same as for January), leeks (June-sown), Parsnips (lift and store), savoys (August-sown late varieties), turnip tops (from swedes, before lifting), white and purple sprouting broccoli (May-sown).

Vegetables in Store.—Same as for January.

MARCH.

Broccoli (April-sown Satisfaction), coleworts (Hardy Green, sown in June), Couve tronchuda (June-sown), kales (same as for January, with addition of Sutton's Hardy Sprouting—a most useful variety at this season), leeks (July-sown), purple sprouting broccoli (May-sown), savoys (August-sown late varieties, finish), seakale (established plants).

Vegetables in Store.—Same as for January.

APRIL.

Broccoli (Sutton's Bouquet, Whitsuntide or Late Queen, sown last April), cabbages (August-sown), kale (August-sown Asparagus and June-sown Hardy Sprouting), leeks (July-sown), lettuce (August-sown winter cabbage and hardy cos), perennial cabbage (two to three year old plants, propagated from cuttings, not from seed), seakale.

Vegetables in Store.—Same as for January.

MAY.

Asparagus (established beds), broccoli (Late Queen or Whitsuntide as for April), cabbages (August-sown), kale (asparagus only, as for April), lecks (August-sown), lettuce (winter varieties, as for April), Peas (December-sown early round-seeded, sown in sheltered south border), perennial cabbage (now nearly at its best), seakale (finish), turnips (March-sown earlies, in good ground).

Vegetables in Store.—Beet, carrots, onions, parsnips and possibly some turnips or swedes.

JUNE.

Asparagus (finishes middle of the month), broad beans (February-sown early varieties), cabbages (as for May), cauliflowers (September-sown Magnum Bonum or Purity), corn salad, or lamb's lettuce (August-sown), kale (asparagus only), leeks (August-sown), lettuce (March-sown spring varieties), peas (February and March sown early varieties, such as American Wonder, Green Gem and Pioneer), parsnips (February-sown, in good ground), perennial cabbage (now at its best), potatoes (Immune Ashleaf or May Queen, sown in February in a sheltered warm border), potato onions (sown early in February, now available if required), turnips (April and May sown early varieties).

Vegetables in Store.—Now finished, with the exception of old potatoes.

JULY.

Broad beans (March-sown), cabbages (August and September sowings), cauliflowers (September-sown All the Year Round or White Queen), carrots (March and April sown early varieties), corn salad (March-sown), dwarf beans (Earliest of All or Canadian Wonder), peas (March-sown earlies), parsnips (February-sown), perennial cabbage (finishes till after autumn frosts have set in, when younger leaves make good eating), spinach (April-sown), spinach beet or perpetual spinach and seakale spinach (April or May sown, thinned and transplanted when 4ins. to 5ins. high), globe artichokes (established plants), lettuce (April and May sown spring and summer varieties), potatoes (first earlies) potato onions (February-sown), onions (autumn-sown), shallots (February-sown), tomatoes (March-sown*), vegetable marrows (April-sown*), turnips (April and May-sown Early Snowball, Early Six Weeks and Early Red or White Early Milan).

AUGUST.

Broad beans (April-sown), cabbages (April-sown earlies), cauliflowers (April-sown Early Giant or Excelsior), carrots (April and May

Digitized by Google

early varieties), corn salad (March-finish), dwarf or climbing French (May and June sowings), peas (April May sown first and second earlies), (February-sown), scarlet runners sown), summer spinach (July-sown, ady bed), spinach beet and seakale (same as July), kohl rabi (April-Early Green), leeks (March-sown), (May and June sowings of summer est), potatoes (second early), potato (February-sown, lift and store), -sown onions and March-sown onion be lifted and stored this month), lift and store in dry weather), (same as July), globe artichokes, (May and June sown Early Snowball, Weeks, Golden Ball and All the Round), vegetable marrows (May-

SEPTEMBER.

(May-sown), cabbages (April and own earlies), cauliflowers (April-sown Giant and Autumn Mammoth), carrots as August), globe artichokes, kale ke shoots and young leaves from ear's August-sown asparagus kale quescent since June), kohl rabi as August), leeks (March-sown), (February-sown), peas (May and sown, finish), climbing French beans scarlet runners (June-sown), lettuce and July sowings of Continuity, Tom and All the Year Round), endive own moss or green curled varieties), (April-sown Earliest of All), spinach and seakale spinach (March-sown), onions (March-sown), tomatoes turnips (same as August), vegetable (May-sown).

Vegetables in Store.—Potato onions, -sown onions and shallots.

OCTOBER.

(May-sown), broccoli (April-sown Protecting), Brussels sprouts (April-cabbages (April-sown late varieties red cabbage), carrots (May-sown earlies intermediates), cauliflowers (April-sown Mammoth, finish), climbing French and scarlet runners (June-sown, finish), artichokes, Jerusalem artichokes, kale -sown asparagus and finish of last August-sown ditto), kohl rabi (May-finish), leeks (April-sown), celery -sown white varieties*), corn salad endive (same as September), (same as September, finish), savoys as September), spinach beet and spinach (April-sown), potatoes (lift), March-sown, lift), turnips (July-earlies, White Stone, Purple Top the Year Round), vegetable marrows -sown, to be harvested at once on of frost).

Vegetables in Store.—Onions (various) and

NOVEMBER.

(May-sown, lift and store), broccoli -sown Autumn Protecting and Winter finish), Brussels sprouts (April-sown), (as for October), couve tronchoda -sown), perennial cabbage (tender leaves see July), savoys (April-sown Green and Early Ulm), carrots (May-sown intermediates and long varieties, lift and celery (as for October), globe artichokes (finish and cut down), Jerusalem lifted and store), kale (April-sown and Early Victoria), leeks (April-parsnips (February and March sown), beet and seakale spinach (July-turnips (as for October, lift and garden swedes (May-sown).

Vegetables in Store.—Beet, onions and early carrots (lifted last month), marrows and potatoes.

DECEMBER.

broccoli (April-sown Winter Mammoth), sprouts (April and May sown).

Stevenson's Selected Sweet Peas

NOVELTIES FOR 1927.

DELIGHT.—A delightfully soft shade of salmon pink. The colour that is usually associated with poor growth, but this variety has full vigour, and is perfect in form and size. To grow it to perfection it should have a cool sheltered position. It is grand under glass. Per Packet of 12 Seeds, 1/6.

ROSE MARIE.—The colour of this variety is unique and is difficult to describe. I describe it as grey-rose or pale wine, and feel sure the variety will appeal to all admirers of my variety Bacchus. Per Packet of 12 Seeds, 1/6.

NOVELTIES 1926.

VENUS.—A superb flower, cream-pink suffused salmon. I stake my reputation on this variety, and consider it will displace all other cream-pink varieties. It has every good point to recommend it—size, substance, form, colour, length of stem, vigour, and perfect fixity. Per Packet, 1/-. 12 Seeds.

CENTAUR.—Deep rich red-cerise. When I state that this variety is richer in colour and larger than **Charming** or **Coralline** I have said all that need be said to recommend it. It is not quite so tall a grower as **Charming**. Per Packet, 1/-. 12 Seeds.

WHITE LADY. After repeated trials of this variety I can with confidence recommend it as the best fixed white in cultivation. It has good well-formed flowers of great size and substance, well placed on stems of good length. Per Packet, 1/-. 12 Seeds.

OTHER VARIETIES OF OWN RAISING.

In 6d. Packets of 25 Seeds, unless otherwise stated.

Bacchus. Wine-colour. 15 Seeds.
Charming. Rose-cerise.
Charity. Crimson.
Coralline. Orange-cerise.
Crimson Glow. Deep crimson.
Cynthia. Pale lavender.
Diana. Lavender.
Faith. Pale lavender.
Fair Lady. Cream-pink.
Felicity. Blush-pink.
Grandeur. Rose-purple.
Guinea Gold. Deep orange. 12 Seeds.
Hebe. Bright pink.
La France. Deep cream-pink.
Lavender Belle. Deep lavender.
Liberty. Salmon-orange.
Poppy. Orange-red. 15 Seeds
Royalty. Purple.
Scarlet Glow. Scarlet-red.
Splendour. Red-maroon.
Sunset. Salmon-orange.
Stevenson's Cream.
Stevenson's White.
Warrior. Chocolate-maroon.
Wild Rose. Old rose. 12 seeds

SPECIAL OFFER to readers of "THE GARDEN." To all purchasers of Sweet Pea Seed to the value of 5/- selected from the above list or from my catalogue, which contains the best of other raisers' varieties, I will present one packet each of **VENUS** and **WHITE LADY**.

cabbages (May-sown late varieties), coleworts (May-sown Rosette), Couve tronchuda (May-sown), celery (second crop, April-sown pink varieties), kales (asparagus, Dwarf Green Curled and Victoria, all April or May sown), perennial cabbage (finish till April, unless specially required), leeks (May-sown), parsnips (March-sown), savoys (May-sown late varieties), spinach beet and seakale spinach (July-sown), white sprouting broccoli (May-sown), garden swedes (May-sown).

Vegetables in Store.—Beet, carrots, onions and shallots, potatoes, turnips, Jerusalem artichokes and vegetable marrows.

Winter Salads.—Outdoor lettuces cannot be relied upon after September, but corn salad and endive are still available up to the end of October if a sufficiency has been grown. China Rose radishes sown early in August will keep us supplied till mid-October. From this date onwards one must necessarily look to indoor or forced radishes and lettuces only, while chicory if sown in April or May will produce fine plants for lifting in October and forcing and blanching like endive as required throughout the winter months. To describe the mode of blanching, however, would require more space than is here available. Chopped celery, beetroot, forced corn salad, onions and cold boiled potatoes are always available for winter salads, as well as mustard and cress grown in boxes in a warm frame.

For winter supplies of parsley and mint some selected roots of each should be lifted early in September and bedded up in a suitable corner of the greenhouse, peach-house or in a cold frame well protected against frost, but fresh mint can be grown in a frame only if kept nipped down regularly so as not to touch the glass.

E. A. SAUNDERS.

CATALOGUES RECEIVED.

Among amateur gardeners the name of Ryders has become almost a household word. Messrs. Ryder and Sons of St. Albans have for years sent out high quality seeds at a very low cost, and annually they produce a seed catalogue which is of particular interest to the amateur. This year their catalogue has been revised and made even more comprehensive. It contains in a concise form a wealth of information on flowers and vegetables. Numerous good half-tone illustrations, as well as a most attractive colour plate (reproduced on our front cover this week) of a painting of marigolds, aquilegias and forget-me-nots by Miss Winifred Walker, are included. We understand that a full-size reproduction of this picture will be sent gratis to every customer of Messrs. Ryders who orders goods to the value of £1 or over.

Messrs. Alex. Dickson and Sons, Limited, of Hawlmark, Belfast, send us their catalogue of "Hawlmark" seeds, which have become famous throughout the horticultural world. Sweet peas are one of their specialities, and many fine novelties, such as Chieftain and Ruddigore, two of their recent introductions, are listed. Sweet pea cultural notes and hints on vegetable growing will be found most useful for reference purposes.

All gardeners who are interested in potato growing should apply for Messrs. Dobbie's spring catalogue. This well known Edinburgh firm are noted for the clean and disease-free Scotch potato seed which they send out, and, as potato diseases have been rampant in many districts this year, it is of the utmost importance that, in gardens where the potatoes were affected, a fresh start should be made this season with clean seed planted on new ground. Vegetable and flower seeds of every description are also listed, and this comprehensive catalogue is well illustrated with half-tone reproductions which greatly add to its value.

Another catalogue from an Edinburgh firm is that of Messrs. Stewart and Co., whose

INSPECTION INVITED, WHEN IT WILL BE FOUND WELL WORTH A VISIT

Please mention THE GARDEN *when writing*

"Stronghold" seeds are reliable from every point of view. This catalogue is particularly strong in standard vegetable and flower varieties.

A fine manual has reached this office from Messrs. Sutton and Sons of Reading, a firm which has done much valuable work to help the gardening world. In their trial grounds new varieties have been raised, and by years of breeding and selection the various strains of flowers and vegetables have been maintained at a very high standard of excellence. Both amateur and professional gardeners cannot fail to find many items of interest in this excellent manual. Flowers are dealt with in the first half, vegetables, lawns and potato seeds are dealt with in the second.

Messrs. Toogood and Sons, Limited, of Southampton, guarantee all the garden seeds which they send out, which is certainly an excellent testimonial for their quality. In their new catalogue will be found all the most up-to-date varieties of flower and vegetable seed, and from it selections suitable for northern as well as southern gardens can be made.

SOCIETY NOTES

Glasgow and West of Scotland Horticultural Society.

AT the monthly meeting of the Society, Mr. Thomas Dagg, presiding, Mr. John Cairns read an interesting paper on the History and Production of Spring-flowering Bulbs, in which he made reference to the introduction of the tulip and hyacinth into western Europe, and showed how their cultivation had been taken up by growers in Holland, who had brought these flowers to their present-day perfection. He pointed out that the improvement in the daffodil or narcissus had originated in England, and drew attention to the work of Dean Herbert of Manchester, William Backhouse of Darlington and Edward Leeds of Manchester, who may be regarded as pioneers in the production of the modern daffodil and of the many lovely varieties to be found among narcissi nowadays. He made reference to many other bulbs and the methods employed in their propagation in the bulb fields. Mr. Cairns also exhibited a series of lantern slides illustrating various features in the propagation of bulbs and work in the bulb fields of Holland and the British Isles.

East Anglian Horticultural Club.

THE annual dinner was held on January 12th at Notts Assembly Rooms, Norwich, when a large assembly of professional and amateur gardeners attended under the presidency of Mr. R. Roll. The toast of the East Anglian Horticultural Club was proposed by Mr. W. J. Payne (Watton) and responded to by Mr. R. Roll (President) and Mr. G. R. Todd (secretary), the latter stating that the membership was steadily growing and it now ranked as one of the largest gardeners' improvement societies in the kingdom.

Mr. H. Perry, in giving the toast of "Success to the Horticultural Trade of Norfolk," said there were in Norfolk 246 fruit growers, 49 florists, 42 seedsmen, besides other branches of the horticultural trade, and many of these carried the name and fame of the county into all parts of the British Isles and, in some cases, overseas. "Daniels Brothers' Seeds," "Daniels' September Black Currant," "Allen's Norvic Roses," "Robert Holmes' Supreme and Kondine Red Tomatoes" were only examples.

Mr. John Clayton, a director of Messrs. Daniels Brothers, Limited, responded. In the course of his remarks Mr. Clayton said he felt sure Norfolk was determined to be one of the foremost horticultural producing counties in England.

22 Exclamation.
23 A prickly pear.
24 Number of leaves in circle around stem.
25 A meadow (curtailed).
26 New Members (abbr.).
27 Tree branch.
28 Short form of "woe."
30 Fourth musical note.
31 A harvester.
33 Thank you.
35 Poison.
37 A labourer's worthy of this.
39 Prepared barley used in brewing.
41 Ascending.
43 Gap in a hedge or fence for animals.
44 Common herbage.
45 Mountain.
46 French land measure.
48 For example.
49 Third letter of alphabet.
50 Almost real.
51 Gardening utensil.
54 A spirit-stove.
56 Not green.
56 Garden tools.

DOWN.

1 Tree bearing an edible nut.
2 Vine-mildew.
3 London Police Department (abbr.).
4 Lichen.
5 Exclamation of contempt.
6 Pronoun.
7 Berry-bearing shrub.
8 Half of "rake."
9 Garden rubbish.
10 Variant of "witch-elm."
14 Pretty white flower, growing in damp places in considerable altitudes.
16 Unfit for tillage.
17 The odorous principle of plants.
21 Number of leaves clover usually bears.
24 Caution.
29 Species of iris.
32 Small bottles.
34 A charm.
36 Expressed oil of roses.
38 Half an em.
40 The trembling poplar.
41 Right Reverend (abbr.).
42 Name given several varieties of plums.
43 A spice; the second coating of nutmeg.
44 Garden paraphernalia.
47 A vivid hue.
48 An early garden dweller.
52 Imperial Highness (abbr.).
53 Two-thirds of "con."

POPPIES

This lovely garden annual Poppy has received its various names from its delicate texture and almost shadowy forms. Shades are endless; a strain of unusual beauty. A number of very beautiful new picotee-edged forms, including shades of tangerine and orange, also give distinction to the strain. There is also a peculiar graining in most of the pink and red shades which evokes admiration from all who have seen these Poppies.

THE GARDEN

VOL. XCI.—No. 2879. FEBRUARY 5, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Of Interest to Town Gardeners.

FOR many years, now, there has been an increasing interest shown all over the country in what has come to be known as Town Gardening. It may be regarded as a specialised form of gardening in that the town gardener has entirely different conditions to contend with from those of his *confrère* in the country. Questions of what plants to grow in limited space, in shady positions and in soil of medium quality become important and demand information of a specialised kind. Gardening journals seldom cater particularly for the town gardener. The information is of a more general nature and must be watered down to suit individual requirements. Since this involves, to a certain extent, the need of some gardening knowledge, which the amateur may not possess, we have decided to assist the beginner in town gardening and the vast army of amateurs who are taking to gardening in the suburban districts of all our large towns and cities, by devoting a whole page, once a week, to town gardening and its problems.

To this end, we have arranged with Mr. R. Sudell, the organising secretary of the London Gardens Guild, to contribute, commencing with this week's issue, a weekly series of notes which will deal with all aspects of this form of gardening. As we wish these to be as helpful to the amateur as possible, they will be on strictly practical lines, indicating the kinds of plants which do well under town conditions, with hints on their culture, methods of treating a limited space and how to get the best possible out of it, by selecting special plants for special situations and so on. Questions of a general gardening nature will also be dealt with in their proper season and all those finer points which make for success in the running of a garden, large or small, new or old. In order to make this page of still greater assistance, we shall publish photographs of various town gardens in various districts, showing what can be accomplished in restricted space and under conditions not exactly of the best. These, we hope, will suggest methods of treatment which others may follow with the same, if not better results.

There are many amateurs' gardens in all parts of every town and city in the country, which could all be made still more beautiful throughout the greater part of the year by the cultivation of all kinds of flowering plants provided the necessary stimulus is given. Much has been done already through the activities of the London Gardens Guild and its affiliated societies in different areas to beautify our towns and suburbs by creating a love of flowers and THE GARDEN wishes to co-operate as much as possible in this very necessary movement and to encourage and assist still further all amateurs who garden in or near a town, by providing reliable and up-to-date information on all questions relating to town and suburban gardens. We will welcome any suggestions from readers on how to make this new feature still more useful to meet all requirements.

Annual Poppies.

ANNUAL poppies have been somewhat neglected by many amateurs, although these flowers thrive in almost any sort of soil. No elaborate preparation of the ground is needed and certainly a few should be grown in every garden. For brilliant colouring and garden display or for providing table decorations few annuals can compete with these annual poppies, considering the ease with which blooms are produced. There is now a fine variety of shades, some most brilliant and striking, others in tones and half-tones of soft art shades and a few are beautifully striped and edged. Shirley poppies in the newest strains are favourites for table decoration, and are to be had in wonderful shades with both double and single flowers. A particularly fine strain is illustrated on our front cover, notable for its beauty of form and colour. A large bed of the newer varieties provides a fine sight in the garden. Also the newer strains last much longer in water. The great objection to poppies is that they do not last long as cut flowers. Much can be done to obviate this drawback. If the flowers are gathered early and just as the buds become erect and show colour they will last longer, and also if the ends of the stalks are plunged in almost boiling water their life as decorative blooms is prolonged.

Although poppies will grow without much preparation of the soil, it is advisable to dig the ground fairly well and work in a little decayed manure. It is not possible to transplant the seedlings, so that a thin sowing should be made where the plants are to flower later. Thin these out to about 9ins. or 10ins. apart. Those who have a new garden and not time to dig and trench for sweet peas or other flowers will find beds of poppies most useful. These annual poppies are quite hardy, and a glance through a seed catalogue will help one to make a selection of up-to-date varieties.

HAVE YOU

¶ *Sown some early peas on a warm south border?*

¶ *Hoed over the surface of your strawberry beds, removed all decaying leaves and given the plants a light dressing of well rotted manure?*

¶ *Pricked off into boxes or frames your seedling cabbages and cauliflowers?*

¶ *Started into growth by placing in boxes of leaf-mould your tuberous begonias? These boxes should be put into a warm greenhouse.*

¶ *Sown seed of antirrhinums, pentstemons, lobelia, begonias and any half-hardy annuals? These should be germinated in a warm atmosphere.*

Plants in Frames.

DAMP is, perhaps, the most formidable enemy to plants in frames, and at the present time great care is needed to keep the occupants healthy. Such things as violas, pentstemons, calceolarias and antirrhinums need only to be sheltered from the rigours of the weather, and at every favourable opportunity the lights should be tilted to admit a free circulation of air around the plants. Dead and decaying foliage should be looked for frequently and removed at once, otherwise fungi will appear and heavy losses follow in consequence. Stirring the surface soil with a hand fork will also be of great benefit. Watering should be done on a fine day and in the morning, so that the interior of the frame may become comparatively dry before closing time. While taking care not to spill any water in the frame, sufficient should be given to moisten the soil to the depth of the roots: mere sprinklings will only add to the trouble it is desired to avoid.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 10, which appeared in our issue of January 29th, have been awarded to—

Mr. A. T. Green,
36, Selwood Road, Croydon.

and

Mrs. W. Naylor,
16, Berkeley Drive, Wallasey.

To each of whom a cheque for that amount has been sent.

DO NOT MISS OUR SPRING PLANTING NUMBER NEXT WEEK.

HARDY ANNUALS TO SOW NOW

SCABIOUS IN MIXED COLOURS.

A USEFUL guide to assist you towards a selection of and in growing some of the most beautiful flowering plants. Annuals by their elastic habit, and wide range of colours are suitable for all purposes and all situations—for filling spaces in the border, for bedding, for the greenhouse, as edgings to paths, and for the rockery. Some are excellent for shady corners, others for sunny situations.

THE FRAGRANT SWEET SULTAN.

FEW owners of small gardens seem to appreciate fully the value of hardy annuals. They cannot, of course, take the place of perennials; still, even if used alone, they can be depended upon to make a brave show throughout the summer, provided the soil is fairly light, the situation sunny, and they are grown with a reasonable amount of care. The seeds must be sown sparsely, the seedlings drastically thinned if in the least crowded, watering must be done judiciously, and a sharp look out kept for slugs, which must be warded off by applying a solution of alum to the soil. Furthermore, the taller kinds should be supported by branching twigs placed among them at an early stage of their growth.

A satisfactory way of dealing with a narrow border—not more than 3ft. to 4ft. wide—such as one generally finds in a small garden is to fill it entirely with annuals in shades of either one or two colours only. Supposing a blue and pink scheme — always very pretty—is chosen, the back row may be of groups of pink cosmos and Lavatera rosea splendens, alternating with others of cornflowers (Centaurea cyanus) and double blue larkspur. All these are about 3ft. high, and should be sown where they are to bloom (the cornflowers particularly resent transplanting) with the exception of the cosmos, which it is safest to start in a cold frame, although it is nearly hardy, as in my north Somerset garden self-sown seedlings often survive the winter. Unless the border is very narrow indeed, the row of these plants can be broken at intervals by clumps of pink sweet peas—say Hercules or Hawlmark Pink—and blue Convolvulus major. The last named can be sown in the open the first week in May, but it saves time to raise it in pots. There are plenty of charming pink and blue annuals from 1ft. to 2ft. in height from which to make a choice for the main part of the border. Among the best are Sutton's double pink clarkia, Sutton's annual blue anchusa, Godetia Double Rose, Viscaria Pink Beauty, Nigella Miss Jekyll, Lupinus Hartwegii cœlestinus, Clarkia Pink Pearl and Jacobæa Double Rose. All should be sown in as large patches as is commensurate with the width of the border. For a "one plant edging" nothing can be prettier than the blue Nemophila insignis grandiflora (this needs specially thin sowing), but, unfortunately, cats have a passion for rolling on it. Godetia Sutton's Dwarf Pink, Viscaria Tom Thumb Rose Gem and Silene pendula compacta are all suitable for the purpose, or they may be combined with Phacelia campanularia—this is a particularly beautiful blue—Nemesia Blue Gem, Convolvulus major and the dwarf cornflower Victoria and sown in patches—blue and pink alternating—along the extreme front of the border in lieu of a straight single flower edging.

A border filled with annuals of every shade of yellow between cream and orange is most effective. The taller sunflowers are scarcely suitable for a narrow border, but there are varieties the height of which does not exceed 3ft. to 4ft. which are quite admissible as back row plants. Here I may say, in parenthesis, that sunflowers, graduated in height from the giants of 6ft. or 8ft. down to the dwarf that reach but 12ins. and of every shade from primrose to deep yellow streaked with red, will fill an angle of the garden—where two boundary walls meet, for instance—gorgeously. To return to our yellow border, in the middle of it can be sown such showy annuals as Coreposis Drummondii, C. tinctoria, Scabious Barr's Yellow Prince, the summer chrysanthemums and Rudbeckia

SOME HARDY ANNUALS FOR SMALL GARDENS.

Name.	*Colour.*	*Height.*
Bartonia aurea	Yellow	1½ft.
Clarkia	Rose-pink, white	2ft.
,, dwarf	,, ,, ,,	9ins.
Chrysanthemum (annual)	Yellow and white	1½–2ft.
Collinsia bicolor	Lilac and white	9–12ins.
Convolvulus major	Deep blue	1ft.
Coreopsis Drummondii	Yellow	1½–2ft.
,, tinctoria	Yellow and red-brown	2ft.
Cornflower	Blue	3ft.
,, dwarf	,,	9ins.
Cosmos	Pink, white, crimson	3–4ft.
Dianthus Heddewigii	Various	1ft.
Dimorphotheca aurantiaca	Orange	1ft.
Eschscholtzia	Shades of yellow, flame and rose	1ft.
,, cæspitosa	Pale yellow	6ins.
Godetia	Pink, white, crimson	1½–2ft.
,, dwarf	Pink	9ins.
Helianthus, dwarf	Yellow	2½–4ft.
Jacobæa (Senecio elegans)	Rose-pink	1½–2ft.
Larkspur, tall double	Blue	3ft.
,, dwarf ,,	,,	1½ft.
Lavatera rosea splendens	Pink	3ft.
,, alba ,,	White	,,
Linum grandiflorum rubrum	Crimson	1ft.
Lupinus Hartwegii cœlestinus	Blue	2ft.

Sweet Sultan	Yellow, purple and white	1½–2ft.
Viscaria Pink Beauty	Rose-pink	1ft.
,, Tom Thumb Rosy Gem	,,	6ins.

Digitized by Google

Golden Sunset, the only annual of its kind. Rather less in stature—but the height of annuals is apt to be variable—are the eschscholtzias in their splendid tones of orange and flame, the not very well known Bartonia aurea which has big golden flowers and pretty foliage, Dimorphotheca aurantiaca (orange daisy) and the yellow Lupinus Menziesii. The daisy is quite hardy in a dry, sunny spot, but the lupin, although not tender, is capricious and dislikes transplanting. It is, however, well worth trying. The colours of Calendula officinale Orange King and Lemon Queen are rich, but the plant is too coarse of growth for a narrow border. As to an edging plant, there is the miniature eschscholtzia, a dainty thing about 6ins. high covered with little primrose flowers, or the ever-useful dwarf nasturtium, shading from cream to deep yellow.

With the exception of the edging plants, all the annuals mentioned above may be grown in patches in the mixed herbaceous border, and many of them are to be had in various colours. To the list may be added the crimson flax (Linum grandiflorum rubrum), scabious, Collinsia bicolor, schizanthus and peony-flowered poppies. To fill small beds in a small garden perhaps the most appropriate annuals are nemesia (various colours), Shirley poppies (white, pink and crimson), sweet sultan (yellow, purple and white), godetia (white, pink and crimson), Dianthus Heddewigii (various colours), Phlox Drummondii (various colours) and ten-week stocks, although I admit that it is stretching a point to include the two last in the category of hardy annuals. A fairly large bed looks well planted with mixed stocks, but it is better to fill small ones with separate colours.

R. E. HEAD.

FOR AN ANNUAL EDGING NOTHING CAN BE MORE ATTRACTIVE THAN NEMOPHILA INSIGNIS WITH ITS CHINA BLUE FLOWERS.

ANTIRRHINUMS for the SUMMER BORDER

AS a plant for blooming in the garden during the summer and early autumn, that may be raised as an annual, or struck from cuttings and wintered in a cold frame, or, in some circumstances, left to chance in the borders and practically treated as a perennial, it is questionable whether any flower during the last twenty years has made more rapid strides in public favour. To-day there is a magnificent choice in colours, so much so that one may for quite a trifling sum bring about very beautiful effects by carefully making a selection. While it is a great advantage to raise seeds in heat in the early year and push them on in warmth before transferring them to a cold frame to harden them before planting out in May, it ought not to be lost sight of that seed sown on a warm border in light soil will produce plants that will follow with bloom, and will not be a long way behind those brought up under—what is so often regarded—better conditions.

In the question of bringing about the best effects, I think it will be found that beds or masses of one colour give more satisfaction than when planted any fashion without reference to colour. The one fact which should not be lost sight of is that, though there may be no greenhouse and no frame, it need not be a barrier to sowing seeds out of doors, and, therefore, no garden need be entirely without antirrhinums. The raising of this plant from a position of almost obscurity to the position of an important flowering plant for the garden has involved much care on the part of those who have made it their business to improve the strains. One such firm, which years ago saw in the antirrhinum great possibilities, has done much towards popularising them. I refer to Messrs. W. H. Simpson and Sons of Birmingham, to whom we are indebted for some charming introductions, such as Mrs. R. F. Felton, bright orange scarlet; Appleby Matthews, orange terra-cotta, lip flushed with yellow; Fire King, orange scarlet, white tube; Sybil Eckford, apricot pink, cream ground, lemon lip; Afterglow, deep orange scarlet self; Estelle, apricot salmon, suffused pink; Purple Robe, rosy purple self.

Other sorts of antirrhinums worth taking into account, especially by those wishing to have masses of one particular colour in the garden, are Bonfire, apricot, shaded gold; White Queen; Carmine Queen; Golden Gem, deep yellow; Charm, soft rose pink self; Black Prince, velvety maroon; roseum superbum, a rose pink self in the way of Charm, but finer; and Monarch, crimson.

One of the great advantages about growing antirrhinums is that one may choose three distinct types of plants: tall, ranging 2ft. to 3ft. in height; medium, 1½ft. to 2ft.; and others, dwarf, not exceeding 8ins. or 9ins. in height, so that there is scarcely any position in a garden in which they cannot be profitably employed. From a long experience with them, I have no hesitation in saying that there are few gardens, however poor the soil may be, where, with a little determination, one cannot have a glorious show of their handsome blossoms, so long as they are given the chance of sunlight. W. F.

ANTIRRHINUMS AND STOCKS MAKE A MOST EFFECTIVE SUMMER BORDER.

EVERGREEN BARBERRIES for SMALL GARDENS

THERE is such a large and varied selection of barberries that the gardener whose space is limited to quite a small area never need feel that these fascinating shrubs are beyond his scope. He will, in point of fact, be able to choose from the members of this genus shrubs that are exactly suited to his requirements. In the evergreen kinds alone the berberis family is especially rich, and in noting a few of these I do not think any more thoroughly deserve first mention than the several dwarfs which have been raised from B. stenophylla. One of the best of these is the so-called B. Darwinii nana, and when I say that it is a replica of Darwin's barberry in miniature, no higher praise can be given it. B. Irwinii is a delightful variety, usually under 1ft., very compact in habit and a most prolific bloomer. The rich green foliage, which in itself is very ornamental in the rock garden, affords a most effective background for the orange-yellow blossoms. B. corallina, which is taller and notable for the vivid scarlet of its buds, is another choice little shrub, and corallina compacta is a dense, close-growing edition of its namesake. B. reflexa is also a stenophylla seedling with curiously recurved leaves and clawed spines, and gracilis nana is "out of the same pod," a dainty gem of a shrub no more than 9ins. to 10ins. high. All the above, save where otherwise stated, grow about 2ft., all have rich yellow flowers and a shapely habit.

B. buxifolia (dulcis) nana has long been a favourite dwarf barberry, its compact growth, ample foliage and golden "lanterns," never failing to appeal. Though it is said to flower indifferently in some gardens, this shrub always does well with me, and, I may add that it is in very poor, dry soil, with its roots wedged between rocks. B. b. nana grows to some 2ft., but in smallness of stature it has been entirely eclipsed by that wee rounded bushling, B. b. n. pygmæa, which you could almost cover with a 6in. flower pot. B. Wallichiana (Hookeri) is a very charming species for grouping on the margin of the shrubbery. It makes a bold sheaf of slender arching branches about 2ft. high the rich green leaves are glaucous beneath and the large yellow flowers, which are produced most lavishly in spring, are followed by sloe-black fruits, which are retained all winter. This old barberry deserves to be more widely known. So also does that much newer species, B. sanguinea, which makes a good companion for the above. It is a good deal taller, but I find it so slow in growth that I am inclined to include it here. It has the same graceful, orderly habit as the last-mentioned, but the foliage is a pale pea-green, an attractive colour at all seasons, and if the flowers are rather a poor yellow, they present a distinct and pleasing effect by reason of the fact that their stalks and calyces are a brilliant crimson. Of somewhat the same style of growth as the foregoing, very compact and orderly, is B. Gagnepainii. With me it does not exceed 3ft. The foliage is spiny and of a fresh pale green, and the flowers, yielded in large clusters, are yellow and of good size. They are succeeded by blue-black berries. B. empetrifolia is always worth a place in any collection of dwarf barberries if only for the fact that it was one of the parents of the splendid B. stenophylla—B. Darwinii being the other. It is, moreover, very distinct in appearance, the leaves being long and narrow, the branches light and trailing and the golden-yellow flowers are usually in pairs. The height seldom exceeds 18ins.

B. verruculosa is yet another species of compact habit and no more than some 3ft. in height. The foliage is a very lustrous green, contrasting well with the ruddy, "corky" bark, and the flowers are unusually large and of a glowing orange yellow. Those who have a partiality for the salmony pink berries of many popular deciduous species, and who may regret that the fruit of the evergreen kinds is comparatively dull, will find satisfaction in B. subcaulialata and B. Wilsonæ. These may not be strictly evergreen, but both are to a great extent. The former never loses its leaves with me. B. Wilsonæ is, perhaps, the most charming of all the dwarfer barberries noted for the brilliant tints of their autumn fruit and it makes a light, spreading bush, usually of no more than 2ft. in height. B. subcaulialata is closely allied to it and equally good in the colour of the berries. B. japonica is very easily grown. It bears clusters of fragrant yellow flowers, and has dark shiny green foliage.

None of the above needs any special treatment. All thrive in a light, gritty, well drained soil and they are quite hardy. An open situation is desirable. Most barberries can be raised very readily from seed, but the dwarf hybrids alluded to must be propagated from cuttings. A. T. J.

BERBERIS STENOPHYLLA IN ONE OF ITS GOOD DWARF FORMS MAKES AN EXCELLENT SHRUB FOR THE SMALL GARDEN.

THE DAISY-LIKE FLOWERS OF ANTHEMIS ARE MOST DECORATIVE.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

CORBOPSIS GRANDIFLORA, A FINE PERENNIAL FOR ALL TOWN GARDENS.

Anthemis (The Chamomile). ANTHEMISES are old-fashioned perennials that have a large following to-day, and are useful in a garden in a variety of ways. Some are dwarf, with silvery foliage and white flowers, blooming in June and July; others reach about a foot or so in height and yield yellow flowers, useful for cutting. The first make good edging plants and all will grow in ordinary garden soil. They should have the benefit of a sunny position, and can be raised from seed sown in the open ground in April; some of them from cuttings inserted after a flowering in sandy soil, and they can be divided in spring also.

Pyrethrum. VERY popular showy garden plants are pyrethrums, hardy, growing well in moderately good soil, and invaluable for supplying cut flowers and for indoor decoration. Moreover, they are profuse with their blossoms, which are single and double. They are among the best plants an amateur gardener can take in hand, as they need but little attention once planted and established, except to divide the clumps every two or three years, an operation which should take place in March. They are wonderfully attractive in a border of hardy plants during the time of their blooming, which is May and June, but if care is taken to cut away the old flower stalks, there will be more flowers in early autumn. Propagation is by dividing the clumps in spring, and from seed, which can be sown in pans of light soil in a cold frame in April. Pyrethrums grow from 2ft. to 3ft. in height.

Agrostemma (Rose Campion). THESE old-fashioned plants, with their white woolly leaves which have a velvety touch, and flattish deep rosy crimson flowers. They are hardy and free blooming, thriving best on chalky or sandy soil. The most popular member of the family (A. coronaria) is of biennial growth, easily raised from seeds sown in the open ground in May, though, as a matter of fact, once plants have been allowed to go to seed, many self-sown seedlings result. They bloom from June to September and attain a height of about 3ft., and are useful in middle rows of hardy flower borders. The flowers, rich in colour, are very attractive, often to be seen in cottage gardens.

Coreopsis. THESE valuable perennial and annual plants which yield their blossoms lavishly are of the simplest culture and should be taken note of by the town amateur, especially, who delights in flowers for cutting. The perennial forms are hardy in light, well drained soils and bloom from June until September, according to variety. Cold, heavy soils should be avoided. Ranging about 2ft. or so in height, they are very attractive in a garden during their flowering period. The methods of propagation open to the grower are by division of roots in March; from cuttings taken from the base of the plants in summer (being inserted in pots of sandy soil and kept in a cold frame and shaded as required), also in the case of annuals, by seed sown in a cold frame, in autumn, in warmth in spring, or sown direct in the border in April.

Asperula (Sweet Woodruff). THIS plant is a favourite in many gardens, and in some gardens is employed in rock-work. Grows about 9ins. high, and is covered in May with masses of small white sweet-scented flowers, the foliage also being fragrant. It is so hardy that it will grow anywhere, and makes such rapid progress where planted that it soon outsteps its boundary, unless checked. Used for planting on grottoes, rough banks, and edges to borders. It needs to be overhauled every year and divided, or reduced if need be. November or April is the best time for the work. There is no difficulty in propagating it, as its roots ramify about a garden if not controlled. Grows in sun or shade. May also be raised from seed sown in spring out of doors where it is wanted to bloom. The sweet scented Asperula odorata is very useful for naturalising. It is also used as a medicinal herb when gathered and dried during the flowering season. A. Gussonii, which bears pink blooms, is an excellent plant for a dry position in the rock garden.

DOUBLE PYRETHRUMS AND ORIENTAL POPPIES GROW WELL TOGETHER IN THE BORDER.

Planting can be carried out during the next few weeks.

THE BUSY MAN'S PAGE

February Reminders.

IN open weather finish the planting of all deciduous trees and shrubs, including roses. Herbaceous borders should be top-dressed with manure, and if the plants are too large they may be divided. Top-dress poor turf on the lawn with a mixture of soot and wood ashes. Plant any edgings to borders. Turn over gravel walks and stir the soil freely among beds and borders of spring flowers.

In the fruit garden there is yet time to plant young trees. Complete any winter pruning without delay. Trees that show signs of being exhausted should be top-dressed with manure or given any liquid stimulant. A little extra nourishment at this time of the year will often have an excellent effect on fruit trees. Another plan is to dig into the ground turfy loam so that it is well within reach of the roots of the trees. The work in the vegetable garden is now steadily increasing. Sowings of early peas may be made, and if there are any broad beans still out these should be put in without delay. Spinach may be sown between peas. If an early supply of Brussels sprouts is required in the fall, sow a pinch of seed now in a box to give plants for putting out in April. Cauliflowers in the seedling stage will need very careful attention. Hardly any water should be given, as the least excess of moisture will cause them to damp off. Carrots, radishes and lettuces may be sown in an early border.

Rambler Roses in Pots.

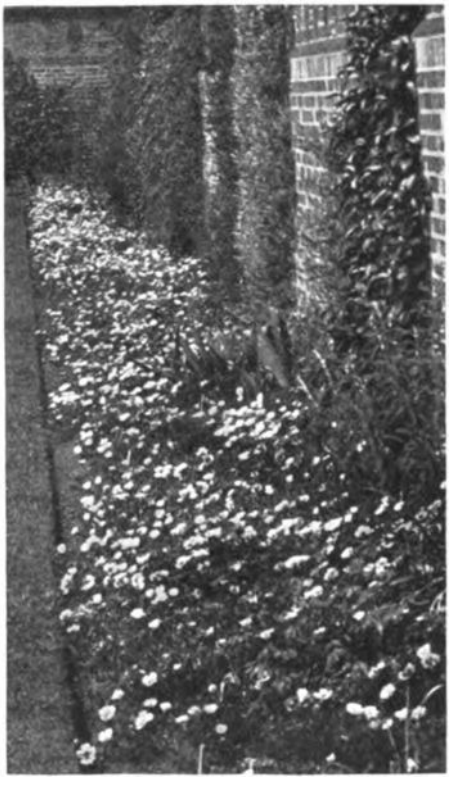
DURING recent years the value of rambler roses as subjects for pot culture has been realised. With simple treatment these may be brought into flower at an early date, when they are most useful for house decoration. Young and vigorous specimens may be potted up at once, a good compost being formed of a mixture of turfy loam, well rotted manure and leaf-mould in equal parts, to which, finally, a little sand is added. For a good-sized rose a "21" pot should be employed, and it is important to see that the drainage is good and also that the soil is firmly rammed down. For a week or two the roses might be left out of doors in some fairly sheltered situation. Finally, the roses may be brought under glass, where, if any heat is available, this should not be more than is necessary just to stimulate a healthy growth. Almost as good results can be secured in an unheated structure. Experience has shown that active growth is stimulated if the roses are given water that is a few degrees above the normal temperature. Twice a week a liquid manure may be given, but the solution should not be strong. Plenty of air and frequent syringings will do a great deal towards keeping the plants in a healthy state and free from green fly.

Seed Labels.

AFTER a sowing of seed, the position is often marked by slipping the packet into a split stick. As a rule the label is soon destroyed, or at any rate is made quite unreadable by the rain. A very good way of getting over the difficulty is on the following lines: Secure some narrow glass bottles, those in which homœopathic medicines are commonly sold do well, and, after folding the packet round a little stick, pop the bottle right over it. Of course, the packet should be folded so that the name of the variety is to the outside, and then it can be plainly read through the glass. Another way of protecting the packets is to dip them in melted candle wax. This enables the paper to resist dampness to any extent and it does not affect the legibility of the printing.

An Annual for a Light and Sunny Position.

FOR a sunny position where the soil is poor and somewhat stony there are no plants so useful as the portulacas. These plants seem to revel in rather barren ground where little else would grow, always providing the situation is not unduly shaded. Most of the forms of portulaca now grown are varieties of old Chilian P. grandiflora, and they exhibit a wonderful range of colour. In many cases there are double forms, and these are especially good on account of their lasting qualities. The plants grow to the height of from 6ins. to 9ins., and form a dense carpet of foliage against which the masses of brilliant flowers show up very



PORTULACA GRANDIFLORA IS A USEFUL ANNUAL FOR GROWING IN A SUNNY BORDER AND IN POOR SOIL.
Seeds can be sown now in a little heat.

finely. The seeds should be sown in a little heat in February or March. When the seedlings are large enough to handle it pays to put them singly into small pots so that by planting-out time sturdy specimens are secured. In early May the portulacas may be set in the open 10ins. or 12ins. being allowed between the plants. Flowering begins at the end of June and will continue for several weeks. The season of bloom may be very much lengthened if the setting of seed is rigorously checked. Sometimes portulacas will sow themselves in the autumn, but, except in a very favourable season, the plants are not always very satisfactory.

When Roots are Shrivelled.

NOW and again one has to deal with the planting of roots which have been kept out of the soil for some time and are badly shrivelled. In such cases it is a very good plan to soak them in water for a time in order to restore their natural plumpness. Fill a pail with rain water and then let the roots soak for five or six hours. They will then be in a much better condition and are ready for immediate planting. This method is particularly useful in the case of anemone tubers, which often shrivel badly; it is worth trying in the case of many other plants for, in no case, can any harm arise.

The Right Use of Fertilisers. The Kinds to Use and Their Results.

ON the proper use of manure much of the success of the garden will depend. Apart from the carbon which the plant secures from the air, all the other food materials are taken up by the roots in a state of solution. Plants have no selective powers in the matter, and if the solution is of the right strength it is bound to be absorbed. If a fertiliser is given without considering the needs of the crop it is possible to bring about results which are the opposite to those required. Here are some useful facts which show the parts played by the principal fertilising agents.

All nitrogenous manures have a marked effect on the leaves and stems of the plant. Thus, a soil greatly enriched with farmyard manure will bring about a rank growth of foliage, and this will be carried out at the expense of flower and fruit. It is easy to realise that nitrogen is useful in the case of those vegetables where the foliage represents the crop, such as cabbages, brussels sprouts, spinach, etc. High-grade guano is a very intense nitrogenous manure which is most useful where a quick leaf growth is desired. Purely chemical fertilisers which help greatly in leaf development are nitrate of soda and sulphate of ammonia. Both these are powerful stimulants which must be used with care according to the directions supplied by the makers.

Potash is an important plant food which is closely connected with the green colouring matter in the leaves and the assimilation of carbon from the air. It is especially useful when vegetables and fruits of large size and good flavour are required. In a soil which has been well prepared and regularly dressed with lime there may be a sufficiency of potash. In most cases it will be found that sulphate of potash may be usefully employed during the growing season. For instance, a pound of sulphate of potash allowed to every square rod of ground where potatoes are growing will be found to be very helpful.

For the production of fruit, using the word in its broad sense to include many common vegetables (*e.g.*, beans, peas, marrows, etc.), some phosphatic manure is extremely important. The most useful forms for the amateur are bone flour and superphosphate. The greatest objection to the first named is that it is somewhat slow in action, and to get the best results only that which has been very finely ground should be employed. Superphosphate may be applied at any time, but it is especially useful in the spring. This has an effect on tomatoes that is almost magical, especially if applied just after the setting of the fruit.

Treating the Lawn.

A GREAT deal may be done towards improving the condition of any lawn by the application of chemical manure. A dressing which may be applied with good effects at the present time is superphosphate of lime 3 parts and sulphate of ammonia 1 part. This should be scattered thinly over the grass, and its effect will be apparent in a dense bright green spring growth.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

We print the following extract from a Garden Talk broadcast from London to all stations on January 5th, by Mr. R. Sudell, in response to many requests.

MANY VARIETIES OF ROSES SUCCEED WELL UNDER TOWN CONDITIONS. THEY ARE AMONG THE BEST AND MOST EASILY GROWN PLANTS FOR THE SMALL GARDEN WHERE EFFECTIVE DECORATION IS DESIRED.

Treatment of New Gardens.

THOSE who live on the new housing estates will have much to do to prepare the garden in time for seed sowing. The general appearance of a *new garden* is one of bareness, and so the first consideration should be to put in climbing plants, shrubs and possibly a few small trees. A few of the quick growing plants for covering fences, sheds, etc., are clematis, especially the red and white varieties of montana, and climbing knotweed (which, by the way, will cover as much as 20ft. square of trellis work in a single season). Vigorous growing roses like Excelsa, American Pillar and Albéric Barbier flourish better than other climbing roses in or near towns. The last named has a wealth of evergreen foliage which makes it useful as a screen plant in the winter garden. There are, of course, many other climbers that could be used, for instance, in the summer, runner beans can be used as a temporary screen between one garden and another, and in new gardens this plant is used extensively for this purpose. Among the shrubs that can be planted for a rapid effect are forsythia (the Japanese bell tree), flowering currant, especially the dark red variety, sumach and bladder senna. A couple of the best trees for making a break in the view from the house would be purple-leaved plum, and laburnum. A tree that does remarkably well in towns and that does not make a lot of growth is the maidenhair tree. If a few plants such as I have suggested are put in straight away on entering a new house, the advantage of this action will be felt in two or three years.

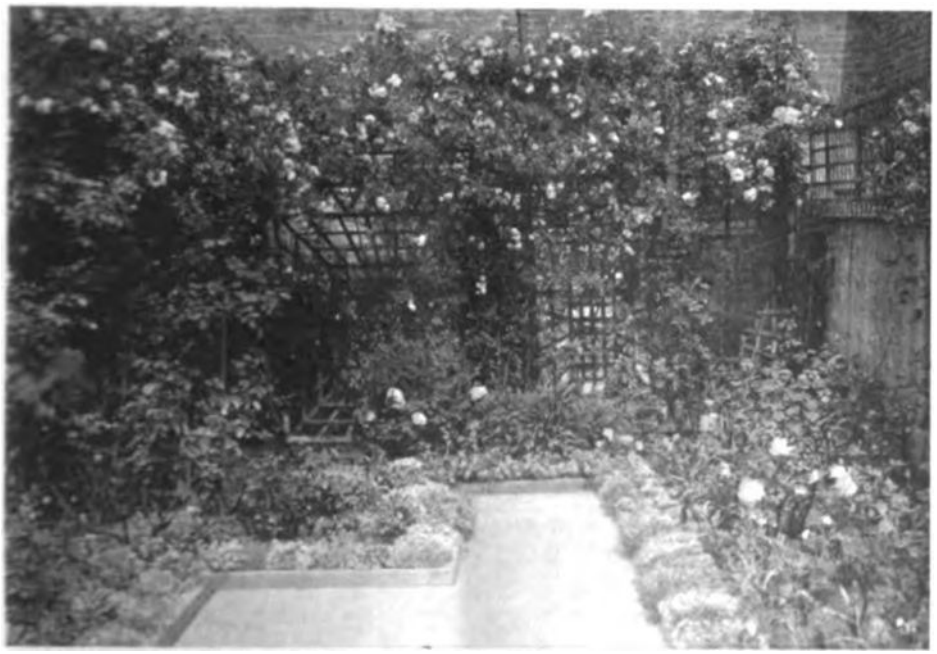
There is a popular belief that plants will not grow well in towns. While this is true for some plants, such as rare alpines and pine trees, it is by no means true for all. The smoky atmosphere, the shade of tall buildings and the sour soil are the three chief difficulties. Suppose we take each of these factors and see if plants in a wild state have to contend with similar obstacles.

The salt laden sea breezes have caused many plants to adopt a protective covering. Carnations are an example. They live by the seaside and have their leaves coated with a film of wax, giving them that beautiful soft grey colour. These plants can grow in the towns, with this coat of wax as a protection from smoke and fogs. All smooth grey-leaved plants will grow well in towns. As for example—carnations, flag irises and auriculas.

The sour soil difficulty is easily dealt with by use of lime and deep cultivation. These difficulties, then, can be overcome, and it only remains to be said that if you love flowers, and give to them intelligent care, you will find that success will come.

Tillage is Manure.

DEEP digging lessens the need for manure, but manure cannot make up for lack of digging. Soil to be "in good heart" should be broken up so that air and moisture can penetrate to the plant roots. The subsoil should be broken to prevent it from becoming water-logged. The surface should, by March or April, be fine enough for seed sowing, or for small seedlings to be made firm when planted. To dig a vacant patch of ground, begin by taking out a trench, putting the soil removed on one side, ready to fill in the last trench you will come to. Break up, or turn over the soil at the bottom of the trench, and throw into it any small weeds and rubbish before you turn the next width of soil over into the trench. Leave the surface rough for the present, specially if your soil is stiff clay. Frost, winds, rain and sunshine will all help to break up the soil particles, and by seed sowing time you will be able to get a fine tilth by knocking down the lumps and raking the surface.



A WELL ARRANGED TOWN GARDEN WHERE TRELLIS HAS BEEN USED TO SCREEN UNSIGHTLY WALLS AND TO GIVE AN EFFECT OF DISTANCE IN LIMITED SPACE.

Roses in Towns.

HUNDREDS of new gardens and old neglected gardens, are just now being dug over in preparation for planting. Most of these gardens are either in or near smoky towns and many of their owners are puzzled as to the kind of plants to purchase first. I regard the first essential as a collection of climbing plants, which will cover the bare fences, old walls and unsightly sheds of outhouses. Roses are ideal for this purpose and if you are at all doubtful whether they will thrive, I should advise the planting of such sturdy types as Albéric Barbier and Excelsa. The illustration on this page, of roses blooming in a London garden fourteen years after planting, should prove to those who doubt, that roses will succeed in town.

In a congested district where even the hardy roses will not thrive, I would advise planting clematis (the purple Jackmanni), climbing knotweed and jasmine, both summer and winter flowering.

NOTES ON THE FLOWER GARDEN

Make Your Preparations Now for a Bright Display During the Summer.

Sedum spectabile as an Edging Plant.

AS an edging for a late summer and autumn border Sedum spectabile is a most useful subject to employ. For one thing, it is permanent, and will give a display every yea rwithout disturbance or re-arrangement. Then, the plant can be relied upon not to exceed a certain height and can be kept well within a limited area. Best of all, it is most decorative all the year round, for when not in bloom its foliage is most striking and gives a perfect finish to the edge of the border.

This sedum never presents a ragged appearance, as many permanent edging plants do. The only time it is inclined to become unsightly is when the flowers are fading, and it is within the grower's powerto remedy this by prompt removal of the flower-stems as soon as the beauty of the blossoms is seen to be on the wane.

SEDUM SPECTABILE MAKES ONE OF THE MOST ATTRACTIVE EDGING PLANTS FOR ANY KIND OF PATH.

There are certain kinds of pathway that call for careful treatment in the way of an edging border, and when there is difficulty in the choice of a subject for the purpose let Sedum spectabile be brougnt to mind, for the plant suits all types of paths—the gravel path, crazy pavement, flagged paths and asphalt. With crazy or flagged pavements this sedum is in appropriate company—it gives just that touch of quaintness and old-time interest to such a pathway that is so often needed. Many a simulation of old-world pavement is spoilt by growing flowers at its edge that are out of keeping with the sentiment intended to be portrayed.

So far as cultivation is concerned, nothing can be easier. The plant is not at all fastidious as to location or soil, although, like every other plant, it appreciates suitable conditions. Once planted, even as a small seedling, it begins to occupy the space allotted to it to the very best advantage, and its activities can be curbed by thinning out the rosettes—each one of which will grow into a plant if inserted in a bed of sandy soil. The root may be lifted, if thought desirable, and divided into smaller plants; but as an edging to a wide border it will be better to give the plant its full scope, within reason, and allow it to form a wide belt of beautiful foliage and blossom all along the pathway edge. The plant is easily raised from seeds, and for preference it likes a moist situation, and the edge of a raised border provides this to a sufficient extent.—H. A. DAY.

A Rose Species Worth Growing, Rosa hugonis.

THIS is a single-flowered Chinese species with bright yellow flowers, and which has the merit of being among the earliest roses to bloom, the plant being at its best about the middle of May. It is not so vigorous as R. Moyesii, therefore it is well adapted for smaller gardens. The blooms, about 2ins. across, are borne singly on short twigs on the main branches, and as these slightly bend over, the effect is a charming one at the time of flowering. The foliage is elegant and small, a fact which makes this rose a desirable one throughout the summer months. It was raised at Kew in 1909, and received the award of garden merit from the Royal Horticultural Society in 1925. It is an exquisite rose that could be employed in a variety of positions, and I once saw it covering a massive boulder, where the blooms were seen to the best advantage.—B.

A North Border and its Uses.

Plants which Do Well in Such a Situation.

SOME gardeners are apt to think lightly of the north side of a garden, and if they do not appreciate its advantages altogether, they view it as the least useful part of the garden. We ought not, however, to forget the use of the north border in the summer, especially in a period of drought, when some of our favourites in sunnier positions languish, and it is a difficult matter to keep them supplied with moisture; neither should we overlook how convenient it is to place a frame in a north aspect, where, for part of each day, coolness is found which suits plants therein—like primulas, cinerarias, solanums and other subjects being brougnt on for beautifying the greenhouse in winter, that with slower development are more sturdy than plants exposed all day to full sunlight. Plants like those mentioned are never better served than when they can be given cool treatment. Most people, in planting bulbs, like to have them in flower at the earliest possible time, and so never dream of planting them under a north wall or fence, but it is a mistake, I think, to look upon the earliest blooms as the best. An experience I gained some years ago in planting a number of Darwin and cottage tulips, and bulbs of that charming Narcissus Mme. de Graaf, which bloomed simultaneously with the tulips, though later than others on the sunny side of the garden, led me to alter my views about the north position being least suitable. It is the same with many hardy flowering plants, including lilies. We are too much concerned in finding some of them a place where they will get every gleam of sunlight, forgetting that shade, as well as sun, has its advantages. I find that in the case of spiræas like S. Aruncus, the goat's beard, and S. japonica and some of its varieties, they are never better suited than when planted in cool quarters as on a north border. Peonies, irises, pyrethrums, lythrums, phloxes, delphiniums, tritomas and hemerocallises (day lilies), come to maturity more slowly, but bloom for a longer time than do similar plants in the full glare of the sun. Exposed to sun all the day, flowers of lilies, like martagon and chalcedonicum, are soon scorched, but give them a place where after midday the sun no longer tries them and notice how they continue! These are only a few examples of the benefit to be derived by planting on a north border.—CLAREMONT.

Diseases in Daffodils.

What to be on the Look Out for at this Time of Year.

NOW that the earliest daffodil spikes are bursting their way through to the open, a very careful watch should be kept to see that each bulb planted emerges with a vigorous green leaf. If a gap is noticed in any group or line, a fine day in early February should be chosen, preferably when the ground is friable, and the soil carefully examined for a depth of 2ins. or 3ins. over the bulb which has failed to appear. At this time of the year the merodon grub, a fat, tough-skinned maggot about ½in. long, worms its way from the bulb and takes up a position just under the soil surface, where, if it is allowed to remain undisturbed, it will pupate and finally emerge as a perfect insect in May, when its destructive work of reproduction will begin. The merodon fly is furry and banded like a small bumble bee, but is easily distinguished by the fact that it does no work, but may be found on a sunny day resting in the neighbourhood of daffodils. It may further be distinguished by the high-pitched sound of its wings, in this respect resembling almost exactly the sound of a hovering fly.

If, on removal of the surface soil in February, no maggot or bulb shoot is to be found, careful investigation should proceed until the bulb is reached, all soil in the meantime being placed in a bucket and subsequently burnt with great care, as it may be infested with "eelworm," which will spread with alarming rapidity. If when the bulb is reached it appears to be perfectly healthy, no further action need be taken, but at this season of the year this is seldom, if ever, the case. The bulb is usually in healthy growth or dead. If it has been attacked by merodon fly the centre will have been eaten out, hence there will be no leaves. In this case the roots are healthy

Digitized by Google

and the bulb may be replanted at once, as it will produce offsets for future years. A bulb attacked by eelworm will throw up yellow, striped, gnarled and twisted foliage. If the bulb is found to be completely rotten, with no root action, it may be assumed to be a case of bulb rot. In either of the latter two cases all surrounding soil should be removed and burnt.

There is nothing so annoying as the discovery of diseased bulbs which have been bought in good faith. Fortunately, there is a method of cure which, in the case of valued bulbs, is both simple and effective. Both eelworm and merodon may be destroyed by sterilising the bulbs during the month of August, when they are dormant. The method is simple in theory, but without special apparatus very difficult in practice. All that is necessary is that they should be immersed in water for three hours at a constant temperature of 110° Fahr. Three degrees below this temperature will fail to kill eelworm and as many degrees greater heat is liable to spoil the bulb. The season following sterilisation will produce healthy foliage, but usually malformed flowers, for it must be remembered that even in August the flower which is to be produced in the following season is already formed and complete in every detail within the bulb. Amateurs who find diseased bulbs should send them to a large grower for the purpose of sterilisation and the keeping down of this ravaging disease.—H. G. LONGFORD.

A Decorative Annual.

DURING the last ten years or so considerable progress has been made in the elegans group of Clarkia, and one of the decided acquisitions is shown in the illustration. This depicts part of a spray of a fine purple variety, probably Purple Prince, and those on the look-out for a plant to place in an isolated bed or corner would do well to take this clarkia into consideration. The reason for partial isolation is the colour; to be seen in all its beauty it must not have any shades of red as near neighbours, otherwise the colours may clash. It will be noticed that the flowers are fully double, and set thinly on long sprays—a fact which makes them light and graceful for cutting purposes. The clarkias attain a height of about 2ft., and if allowed the requisite space—say a foot or more apart—they will develop into fine bushy plants. These brilliant annuals can be sown both in spring, during the next few weeks, and in autumn, while from an August sowing some excellent plants can be had for growing in pots in the cool greenhouse. — W. B., *Chepstow.*

A GROUP OF STATELY CLARKIAS.
Seeds can be sown now.

An Early-Flowering Shrub

AS an early-flowering shrub Forsythia suspensa is well known, but the varieties of F. intermedia are undoubtedly the best in the genus. F. intermedia is a hybrid between F. suspensa and F. viridissima. Three varieties are in commerce, *viz.*, densiflora, vitellina and spectabilis, and it is the last-named form to which I desire to draw attention. This is the finest forsythia with which I am acquainted, and a batch is grown on each year for the greenhouse, where it can be had in bloom early in the month of January. It is a more or less erect shrub some 3ft. to 6ft. in height, and the large deep yellow flowers are produced in much greater profusion than is the case with F. suspensa. The flowering period outside is March and April, according to the mildness or otherwise of the season. This plant is well adapted for beds, bold groups in the shrubbery, and in small gardens a corner could be found for at least one example. If the branches are cut when the flowers are in bud, they will open beautifully in a warm room, and keep fresh for a week or two. Where a few branches or twigs are removed with an eye on the future welfare of the shrub, very little, if any, pruning will be required. When such work becomes a necessity, thereby to prevent overcrowding, it ought to be carried out immediately after flowering. Pruning consists of the removal of any shoots that are likely to cause overcrowding, and to get the best results it must not be subjected to hard pruning so often practised on the popular F. suspensa.

FORSYTHIA INTERMEDIA IS A FIRST RATE SPRING-FLOWERING SHRUB FOR A SMALL GARDEN.

Forsythias will thrive in any good garden soil, but it should be remembered that they are gross feeders, so in a poor root-run an annual mulching of manure will be beneficial. This forsythia is increased by cuttings if shoots with a heel are selected in July or August and placed in a cold frame.—T. W. B.

The Winter Aconites.

MANY gardens will early be aglow with the brilliant golden colouring of these harbingers of spring, and it will be well for garden lovers to take note of the beautiful effects obtainable from generous plantings of these small bulbous subjects; they are never more charming than when freely colonised under the branches of deciduous trees or in thin woodland among hazel; or, again, they may be planted in the rock garden or in the hardy flower border. The ordinary E. hyemalis is the most suitable species for free planting, and the more generous the massing the more effective will be the subsequent results; Eranthus cilicica has a finely cut ruff, this and the stem shaded bronze, while the flower is, if anything, of slightly paler colouring than the common species. If the corms are planted in July and August, or as soon as dormant roots become available, excellent first-season results may be confidently expected.—R. E.

THE FRUIT AND KITCHEN GARDEN

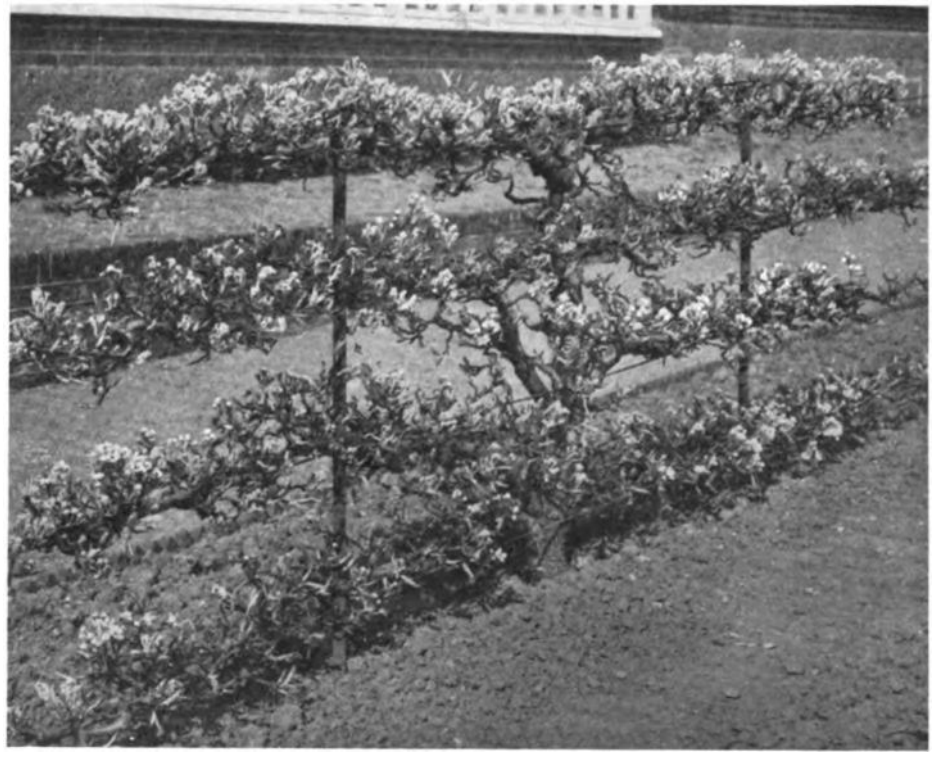
The Apple Tree for the Small Garden.

How to Grow and Train Espaliers.

APPLE trees trained as espaliers are specially suited for growing in gardens of limited size, as they may be placed to form the edgings of paths or as divisional lines in the kitchen garden. To grow apples as espaliers, care and attention to details of training and pruning are needed, but this trouble is well worth while, as some of the finest dessert fruit may be obtained from trees trained as espaliers. Properly grown they make admirable screens for the kitchen garden and in themselves are very attractive.

There are two types of espalier, *viz.*, the horizontal espalier and the vertical or gridiron espalier—the former being the more commonly grown.

The espalier tree should be trained on wires and should usually be a four-tiered tree for edging purposes. Two stout posts



A FOUR-TIER ESPALIER APPLE TREE TAKES UP LITTLE ROOM IN THE GARDEN.

are required, one at either end of the space to be covered and five strands of wire should be strained between them. The first strand should be placed 18ins. from the ground level and the others at 1ft. intervals. It is desirable that some method should be adopted for tightening these wires if they so require it.

At intervals of 10ft. or 15ft., other posts of a lighter structure should be placed alternately on either side of the wires and the wires attached to them by means of strong staples. This will give a solid structure to which the trees may be trained. The total height of the espalier above the ground will thus be 5ft. 6ins.

Buy from the nursery young two-tiered espalier trees. These may be developed into five-tiered espaliers as follows.

Cut back the central leader to 15ins. each spring (February or early March), when several growths will arise from the buds nearest the cut end. Select the strongest and carry it on as the leader. Two of the side shoots in the best position should be trained along the wire to the right and left, tying to the wire. Continue this each year until the desired number of tiers is obtained, when the leader should be removed entirely.

For the first few years it will be very necessary to pay careful attention to the training of the tree. The espaliers should be planted 20ft. apart so that the side branches have to be developed in order to cover the 10ft. horizontal space allotted to them and at the same time be clothed with potential fruiting spurs. The side branches should be pruned each year to make wood growth (extension), always pruning to an under bud until the space which they are to cover is filled.

Pruning requires special care, so that growth may be even and the flow of sap carefully regulated. It is desirable to pinch and stop laterals in summer on the side branches. Those laterals arising from upper buds should be stopped at five leaves and sub-laterals at two to three leaves. Laterals arising from under buds will not be so vigorous and may be allowed to grow more. Start pinching operations at the top and centre of the espalier, so that the sap may be forced towards the bottom branches and to the extremities.

Winter pruning consists in cutting back these laterals to one or two good buds so that they will form fruiting spurs. Varieties specially suited for espalier trees are Cox's Orange Pippin, Allington Pippin, Rival, etc., but any good dessert variety is suitable.—H. B.

Late Planting of Fruit Trees.

WHEN planting fruit trees late in the season, several precautions have to be taken which are not so necessary if the trees are planted in the late autumn or early winter. The trouble occurs because the buds on the fruit trees are beginning to be active and require food material before the root system has had an opportunity to take hold. This means that the buds are drawing upon the food reserves in the tree, which might otherwise be helping to develop new roots. Therefore, in general, it is desirable to avoid planting fruit trees at this time of the year. If, however, for some reason or other, it has not been found possible to plant them earlier, if certain precautions are taken they may be planted late with every prospect of getting away well.

Planting should be done on a fine, warm day, when there is not too much wind. Trees which are to be transplanted should be carefully lifted and the roots trimmed with a sharp knife, cutting large roots so that the surface of the cut does not face towards the surface of the soil. The holes in which the trees are to be set should be dug sufficiently deep so that the bottom may be covered with some dry soil from the potting shed, a good mixture being two parts of loam to one part of leaf-soil. This should not be too dry. Having covered the bottom of the hole with about 6ins. of this mixture, place the tree roots on top, spreading them out carefully and cover with some more soil of a similar compost, working the soil in between the roots, firming with the hands. Completely fill the hole with soil and lightly ram. New trees from a nursery should be treated in the same way.

Every precaution should be taken while handling the trees to see that the roots are as little exposed to drying winds as possible. If the weather remains fine and dry for some time after planting, a small amount of water given to the roots would be advisable.

Strawberry Plants in Beds.

PLANTS in open borders do not need disturbing, especially at the roots, during the winter months. That is, they are not benefited if their roots are unduly disturbed, but are all the better for proper attention now. The top crust, not more than an inch deep or so, should be broken now if proper surface dressings were not put on late in the autumn. Where the necessary attention had been given then, only a litter mulch will be required now, which will serve, in part, to keep the ripening berries from being soiled in due course. About 3 oz. of basic slag per yard run of row should be applied now, scattering the finely ground slag evenly on the surface of the soil and, as stated above, just prick up the surface and let in the slag so that it will mix with the soil. Then lightly dust the surface around each plant with soot, and, finally, apply the littery mulch. If basic slag cannot be used, apply 3 oz. of bone-meal per yard run of row. By the time that new roots begin to grow freely in spring, the stimulants applied will be in a more suitable condition to benefit the plants. Beyond the removal of coarse weeds by hand, nothing more will be needed except the netting of the beds and the gathering of the crop, until mid-July. Where rooted runners were planted last autumn, weekly attention will be necessary now if the weather is frosty. Frost causes the plants to be lifted in the soil and left raised above normal level. After each thaw the soil should be pressed down, by hand, around each young plant.—G. G.

Red Cabbage.

MOST gardeners grow at least a few red or pickling cabbages, and, if seed was not sown in autumn, it is time to get the seed in now. Sow in heat; prick out the plants into boxes of loamy soil, keep them a fortnight longer in the greenhouse, and, finally, transfer to the frame. Harden off gradually and then plant out in April. Autumn-sown plants still in the seed-bed may be planted out at any time, as soon as a short

Digitized by Google

spell of growing weather brightens things up, the plants in this case being lifted with a good ball of soil. When red cabbage seedlings settle in their final quarters, stimulate them with a little artificial manure or by liquid feeding, for it materially aids in final success to get these "rather slow" plants well going in the early stages. In order to get really large heads, autumn sowing of seed seems practically essential; spring-sown plants never seem to get as large as the others, although good medium-sized stuff may readily be grown. For very large heads there is nothing to beat a selected Giant or Large Blood Red, although practically all other kinds, sown in autumn, will yield enhanced crops; for spring sowings and fairly big cabbages, the Red Dutch type is excellent; smaller sorts are the Dwarf Blood Red and Niggerhead. I specially recommend the last-mentioned for sowings at this time; it yields comparatively small heads, but these are as solid as can be, a deep blush red right to the very heart; moreover, they do not burst, like some cabbages, and they can be left in growth until required.—LANARKSHIRE.

Brussels Sprouts.

Varieties which have been Tested and Found Suitable for Scottish Gardens.

TO many, Brussels sprouts are just "sprouts," but growers should not overlook the fact that there are essential differences in varieties well worth considering. First of all, I may add that a few of the newer varieties can only be described as enormous. I grow two kinds—Taurus and Fillbasket—plants of which, when given room to grow, will reach to an average height of 4ft. and carry good crops of sprouts, as large as and occasionally larger than tennis balls. Such sprouts are not coarse; they are firm, sweet and of excellent flavour. Among what may be called ordinary kinds, the aim has been to get varieties which give hard sprouts in a compact mass from near the ground to the crown; not all kinds give a uniform result, but from lengthy tests I speak in favour of Improved Dalkeith, Darlington, McArthur's Triumph and Castle Huntly. In addition to these, I give Solidity and Favourite, which are not of great merit in regard to the size of the sprouts, but their small and hard sprouts remain hard, firm and of delightful flavour, longer than any others; indeed, I rely on them for the very last supplies. Much of the success in growing sprouts is due to correct cultivation: the ground for them must be well dug and well manured, but, above all, it requires to be firm, and the plants also must be firmly planted. Again, sprouts must have lots of room—in this most growers err. I advocate planting sprouts and early cauliflowers alternately, so that when the cauliflowers are over, the sprouts can have enough space. Growers in Scotland prefer early planting and, naturally, early sowing or autumn sowing: April sees practically all the sprouts *in situ*.—CLYDESDALE.

How to Grow Dwarf Beans in Pots, Boxes and Frames.

FROM twenty pots of dwarf beans which are grown in pots or boxes placed in a warm greenhouse or in a frame on a mild hotbed, several dishes of beans may be gathered many weeks before it is possible to obtain the pods on outdoor grown plants. The plants are very susceptible to the attacks of red spider, and from an early stage of growth of plant a keen watch is necessary. Not a single syringing time must be passed without this essential work being done. The best times for syringing are early in the morning and near midday. It is only safe to omit the midday syringing when the weather is dull and very cold. Five plants may be grown in a 6in. pot, seven in an 8in. pot and nine in a 10in. one. Larger pots are not desirable, boxes being a good substitute for them. The compost should be made up of fibrous loam, chiefly with a small quantity of well rotted manure and leaf-soil where the loam is of a clayey nature sow the seeds in one half the compost, the other half being utilised for filling up the pots when the young plants are showing their first flowers. Dwarf beans in pots or in beds in heated frames may be beneficially watered with liquid manure and nitrate of soda when the first pods are forming. One ounce of nitrate of soda will be sufficient for 6 gallons of water and for two waterings, a fortnight being allowed between each watering. Syringe once a week with clear soot water and place mats on the frames at night, even when the frames are heated, as the air near the glass becomes cold. Dwarf beans treated in this way are easily managed, and give a good crop provided the plants are kept free from insect pests and are well fed.—HANTS.

FEBRUARY FLOWERS IN THE ROCK GARDEN

EVEN the smallest rock garden can be persuaded to provide at a reasonable cost quite a beautiful display of flower as early as February. It is quite unnecessary to wait for the coming of spring before one is drawn towards the rock garden, and, though bulbs must necessarily form part of February's feast of colour, there are many plants upon which we can safely rely. Here is a list of a few of our February visitors, some of which may even be flowering in January.

Crocus Sieberi.—This is a very lovely crocus, whose only fault is the weakness of its stem, which is apt to be beaten down by heavy rain. The temporary protection of a pane of glass when in full flower will be appreciated.

Cyclamen Atkinsonii.—This exists in several colours, ranging from pure white through deep pink to a rich magenta. All forms are most beautiful and but rarely seen in rock gardens, though eminently suitable, as they are so very diminutive.

Cyclamen Coum.—This is noted for its gloomy leaves wholly unrelieved by markings. The colour of the flowers is, however, exceptionally deep and rich.

Daphne Blagayana.—One of the peers of rock shrubs. The flower buds resemble knobs at the end of stiff spikes, and when they open display flowers of a creamy white tint and most entrancing scent.

Erica carnea.—Here we have a truly indispensable plant as it revels in lime, keeps quite dwarf, and persists in flowering throughout the first five months of the year. It is quite the brightest of our winter-flowering subjects for the small rock garden, and ridiculously cheap.

Helleborus niger and H. orientalis.—These may not flower until they have become established, but that is well worth waiting for. The huge pure white flowers of H. niger and the indescribably curious pinky green flowers of H. orientalis are most fascinating. By degrees the flowers of both varieties fade to a brilliant green.

Muscari azureum.—The grape hyacinths are always anxious to be early in the field and are, perhaps, the earliest blue flowers we have.

Narcissus minimus.—Almost unquestionably the ideal bulb for the small rock garden. These tiny daffodils are less than 6ins. high and are perfect miniatures of their big brothers. If planted under some carpeting plant or prostrate shrub the effect in flower is exquisite.

Primula Winteri.—This is not, perhaps, inexpensive, but the outlay is well repaid by the peerless colour of the flowers, difficult to describe but most distinctive—soft luminous lilac blue is a wholly inadequate rendering. This plant requires protection from winter wet.

Saxifraga (Kabschia, oppositifolia, and Engleria varieties).—Here the question of selection becomes positively embarrassing. Of the Kabschia saxifrages flowering in February, SS. apiculata, Burseriana crenata, Elizabethæ, Faldonside, Irvingii, Jenkinsæ and sancta will provide abundant interest and exceptionally beautiful colourings. All the various colour forms of S. oppositifolia are delightful, and of the Englerias SS. Grisebachii and Stribnryi are to be recommended as their rich crimson velvet bracts arrest the eye at once. For Kabschia saxifrages a small piece of glass when heavy rain sets in will prevent the washing away of the lovely colour.

Scilla.—Here we fall back once more on bulbs and find trustworthy friends which do not seem to mind what the weather is like.

There are many other early-flowering plants, but all those mentioned were in full flower in February, 1925, in the writer's tiny garden.

A DRIFT OF SAXIFRAGA APICULATA ALBA, A FINE EARLY-FLOWERING ROCK FOIL.

WHAT OUR READERS SAY

NON-FRUITING OF PERNETTYAS.

SIR,—I notice that "H. S. B." of Pangbourne asks in THE GARDEN for January 15th for the reason why his pernettyas are not fruiting. The "Service Bureau's" answer to this suggests that "the male and female flowers of this shrub are borne, at least in some cases, on different bushes." I have never personally examined a pernettya to verify this, but I have always understood that such is the case, and that one must have an occasional male or pollen-bearing bush to fertilise the flowers of the berry-bearing bushes. The temptation—unless one happens to know this—in choosing bushes at a nursery or to take from one garden to another, as in "H. S. B.'s" case, would be to take all the finest fruiting bushes. The pollen-bearing bushes, of course, do not bear berries. I think "H. S. B.'s" best plan would be to write to a reliable shrub nursery asking for a male bush of pernettya, and I think if he plants it among his others, he should get a crop of fruit next year. The same thing applies, of course, to sea buckthorn (hippophæa) and also to Euonymus japonicus. Choosing only fruit-bearing specimens of such shrubs is rather analogous to setting up a pen of poultry and choosing only the sort of birds that lay eggs and none of the sort that do not lay eggs. In this case one would at least get eggs, though one could not expect chickens; with the pernettyas you do not even get berries—after the first year.—CLARENCE ELLIOTT, *Stevenage*.

ROSES IN THE SOUTH.

SIR,—The weather in my district during the last month of the old year was almost perfect from the gardener's view-point. Planting conditions were ideal, for the November rainfall of over 8ins. had thoroughly soaked the parched ground, and right throughout December rain only fell on four occasions. This gave me a good time for thinning out the shrubberies, replanting subjects that had become overcrowded, making new plantations of fruit trees and roses, for which a fine dry spell is very necessary to do the work properly. In making new rose-beds I find it essential to use heavy loam to mix with my light sandy soil. People are ill-advised in adding real clay to the soil, thinking this as good as heavy loam. It is a costly mistake, for clay remains in chunks of tough, putty-like substance, never properly mixing with this type of soil, for we rarely have sufficient frosty weather to break it to pieces to enable proper amalgamation. Though the winters are never severe, yet I find some varieties of roses rarely flourish, but gradually die out, such as Golden Emblem, Christine, Mme. J. Groslez, Lady Inchiquin, Mrs. Haworth and F. W. Dreer.

The following are general favourites and can be well recommended for this district: Mrs. Wemys Quin, Mrs. Beckwith, Rev. Page Roberts, Mabel Morse and Souvenir de Claudius Pernet for yellows.

Pinkish Shades.—Mrs. H. Bowles, Mme. A. Chatenay, Mme. Butterfly, Charles E. Shea, Mrs. Henry Morse (very susceptible to mildew in certain districts), Lady Pirrie, Prince de Bulgarie, Caroline Testout, Lady Ashtown and Pharisaer.

Red Shades.—Covent Garden, General McArthur, Templar (does not do well out of doors in the majority of districts) Hugh Dickson, Lord Charlemont, Etoile de Holland, K. of K., Red Letter Day and Hoosier Beauty.

Orange Shades.—Mme. E. Herriott, Los Angeles, Gorgeous, Lady Hillingdon, Margaret Dickson Hamill, Frances Gaunt and Wilhelm Kordes.

Whites.—Frau Karl Druschki, Mme. Jules Bouche, Mrs. H. Stevens, Molly Sharman Crawford, Clarice Goodacre and Mrs. Foley Hobbs.

The above may be tried with confidence in very light soils.

Such varieties as Betty Uprichard, The Queen Alexandra and Sunstar are asked for as novelties, and there is an increasing demand for them every year.

Among the newer climbing roses, or rather rambler roses, the following will become popular when better known: Albertine, a deep coppery pink, most brilliant in the bud stage, large flowers and needs little pruning. François Juranville, deep salmon pink, large flowers and good foliage. Auguste Gervais, coppery yellow and salmon rose, of vigorous growth. The Beacon, bright red with white eye, strong grower. Augusta Nonin, an older rose yet but little known, is a fine bright pink with large, stiff trusses of flowers. Yvonne, a pretty shade of pink, sweetly scented. Romeo, a deep red, a fast grower, flowers double. Sander's White, the best of the whites, with bright shining foliage and many prickles. Jacotte is another thorny subject with flowers of saffron yellow as large as those of Mme. Herriot and as attractive. Alex Girault and Diabolo are reds with large flowers if other reds are wanted. Emily Gray, yellow, and Mermaid, single cream, are now so well known as to be in good demand. Both are first-class varieties. The latter is especially fine as a tall standard.

The most important point in rose culture is to trench the ground previous to planting in early autumn, adding plenty of well rotted manure. Then, in March, after pruning, to give annually a heavy dressing of farmyard manure and cover over with soil or dig in between the plants. Treated in this way I saw some plants of General McArthur which were planted about twelve years ago with plenty of shoots 4ft. and 5ft. long. If the summer be hot and dry, a good mulching of half-rotten manure is very beneficial.

Noting a reference to Gerbe Rose in a recent issue of THE GARDEN, I would add my testimony to its wonderful beauty and vigorous growth. I would like to say how greatly the new features of THE GARDEN are appreciated. Every page is packed full of interest.—F. L., *Bournemouth*.

A NOVEL MUSHROOM BED.

SIR,—With reference to the note and Editorial query on page 13 of your issue dated January 1st, in regard to the use of "Adco" manure as a substitute for stable manure for making up a mushroom bed, I should like to offer the following remarks. I have never myself so grown mushrooms as yet, but I have found this synthetic manure invaluable for growing really good crops of vegetable marrows and ridge cucumbers in the open in Cornwall. The climate there is roughly, on the average, some 20 degrees Fahr. higher than in the Midlands during the summer months, and this extra sun heat acting on the synthetic manure doubtless contributed very materially to the success obtained. In the "Adco" manure itself, so far as I could observe, there was little or no latent heat, and I therefore doubt very much if this manure would do for growing mushrooms unless the bed were made up on top of or round hot-water pipes in a darkened and properly prepared mushroom house, such as we had at Carclew (Cornwall). In such a case, however, if the manure were well moistened when making up the bed, and afterwards kept sufficiently damp and evenly warmed throughout, there is no reason why a good crop of mushrooms should not be so grown. In any case it would be an experiment well worth trying.—E. A. SAUNDERS.

SWEET PEAS AND STREAK.

SIR,—In your issue of THE GARDEN dated January 15th, 1927, page 34, I noticed an article on "Sweet Peas," by "C. H. A. S." The article I like very much and it is very helpful, but before you can obtain those beautiful blooms, one has to find a cure for the *streak* which is present in nine out of every ten gardens. I have grown sweet peas to perfection until the flowering stage, then they are entirely wiped out with the streak. I am an old hand at growing sweet peas and only a very few times can I remember being free from this streak, so should be most grateful if "C. H. A. S." can say a word or two on the matter. Messrs. Carters, Raynes Park, say there is little known of the disease. Perhaps your correspondent "C. H. A. S." or any of your readers may be able to give some useful information on the question.—C. H. W.

LOBELIA CARDINALIS.

SIR,—In your issue of THE GARDEN of January 1st, "W. L. L." writes on "Lobelia cardinalis and its allies." This plant is plentiful in Canadian ditches; but its foliage is green, not coppery or red and it seems to like full sun, so that I wonder if "W. L. L." knows the real Canadian wilding? Lobelias syphilitica, pulonela, spicata, Kalmii, inflata and Dortmanna are all Canadian wildings also. As L. cardinalis survives Canadian winters it should not need protection in England and we give it none here, where, so far, it seems to be quite happy. However, one feels it is rather tempting Providence to claim complete hardiness for any plant. I should much like to see L. Tupa, which sounds a very attractive plant, but Chile lies far out of my reach—alas.—EVELYN BYNG OF VIMY, *Thorpe Hall, Essex*.

A REQUEST.

SIR,—I write this letter hoping that your readers can help me. A few weeks ago Messrs. Sutton sent me out an order of five pounds worth of vegetable seeds, and these arrived in excellent condition. I hope that any gardeners who are now ordering seeds from Sutton will be so considerate as to put in an order for a packet of onion, leek, cabbage or egg plant seeds for the immigrants in Albania. The seeds sent from England last year were wonderful, the local seeds were very inferior.

There are this year 600 poor families all asking for English seeds. If several orders are received Messrs. Suttons will be able to pack them all together cost free, and I am allowed to receive them free of import duty as they are for the poor immigrants. A 1 oz. packet is enough for two families, and there will be many messages of grateful thanks sent to the kind English gardeners.—R. V. PENNINGTON, *Ospedale, Durazzo*.

CYANOGAS FOR RAT DESTRUCTION, AND SCILLA MARITIMA.

SIR,—Two queries caught my eye under the heading "What Our Readers Say" in THE GARDEN, page 44. With regard to cyanogas, I saw a demonstration on the use of this on a poultry farm a few months ago, and was greatly impressed with its efficacy for destroying rats in the open. A distributor was used, rather like a large motor tyre pump, with cylinder, plunger and flexible tube. The tube was put just inside the rat-hole and the poison pumped in in the form of powder which instantly turned to gas. A number of rats were killed in the

Digitized by Google

hole, but in most cases several rats bolted and, after running 3yds. or 4yds., dropped dead. Gas could be seen issuing from a number of holes; these holes were then blocked up, when a move was made to a fresh hole or series of holes. The method is very simply carried out, though, of course, in using such a deadly gas great care must be taken.

With regard to Scilla maritima as a rat poison, this undoubtedly has its advantages, and I understand that the New Zealand Government has recently imported bulbs with a view to cultivating it for home use. I found the plant growing wild in great quantity last April in Majorca and brought a number of bulbs home with me. When full size they are about as large as coconuts, and they grow quite on the surface of the ground, sometimes singly and sometimes in groups of three or four. There were thousands of them scattered up and down on the rocky hillsides in certain districts, always in full sun. The plant when I found it was in full leaf, large, coarse foliage like that of one of the stronger colchicums, though even bigger. This foliage dies down in summer, and later in the year a 3ft. to 4ft. flower-spike is thrown up. I believe the plant can be grown in the open in this country, at any rate in the warmer southern districts, but I should say it would always be advisable to give it the hottest, sunniest position possible, and well drained soil. I feel pretty sure that it would be essential to plant the bulbs as they grow in nature, quite on the surface of the soil, the whole bulbs fully exposed. I doubt, however, whether it would be profitable to cultivate it in this country as a rat poison, though it is undoubtedly an interesting plant and might be grown for home use on a small scale. An interesting use to which the plant is put in Majorca is as a cure for certain fruit trees. I saw fig trees with Scilla maritima planted close around the base of the trunk, and I was told that this is done to cure sick fruit trees—with how much success I cannot say.—C. E.

THIS MONTH IN THE GREENHOUSE

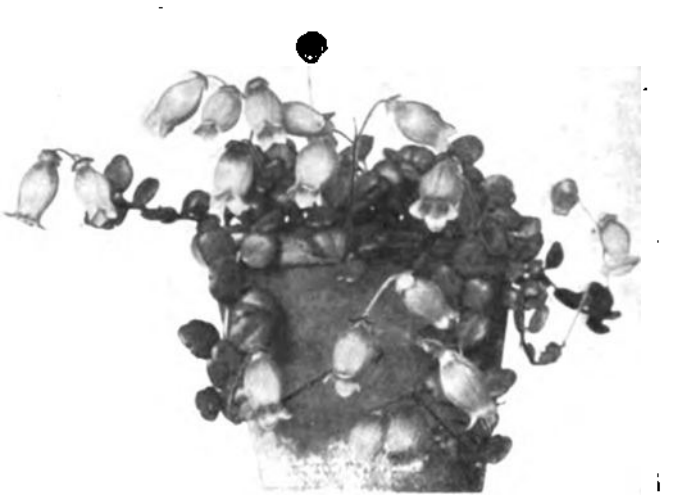
Mignonette as a Pot Plant.

THIS fragrant-flowered annual is deservedly a favourite with everyone, and as a pot plant it is an exceedingly useful subject for the decoration of the cool greenhouse. Seed may be sown at the present time, using 60-sized pots, well drained, and filled almost to the top with a mixture of fibrous loam and mortar or lime rubble. This latter is a very important item, and without it success cannot be expected. Pass the mixture through a ½in. sieve, and press firmly into the pots. Sow thinly, cover the seeds with fine soil, and place in a cool frame, with a piece of glass over the top of each pot. Keep close until the seedlings appear, when the glass may be removed and ventilation given on all favourable occasions. Thin the seedlings out to two or three in each pot, and keep as near the glass and in as light a position as possible. Always water with the greatest care, and when the roots reach the sides of the pots and before the plants show signs of starvation, shift into larger pots.—H. E.

A Novel Plant for Baskets.

AN ideal subject for those enthusiasts who are always looking for something new to grow in hanging pans or small baskets is to be found in the charming Kitchingia uniflora, which is now coming into flower. It is a member of the crassula family, and was introduced to this country about twenty years ago; but although occasionally exhibited at flower shows, it has never become generally grown. This is rather surprising, as it is not a difficult subject to manage; for, despite the warmth of its native home, said to be Madagascar, it flourishes quite well under ordinary cool greenhouse treatment.

In general habit, it is a slow-growing, prostrate, sedum-like plant, having slender creeping stems with thick rounded fleshy leaves; and if allowed to come into contact with the soil, or grown under moist conditions, roots will readily grow from the nodes. It prefers a soil consisting mainly of loam, with peat, and should be kept fairly moist, especially in the summer; otherwise, very little attention is needed.



KITCHINGIA UNIFLORA WITH ITS GRACEFUL PINK BELLS, AN IDEAL PLANT FOR POT OR BASKET CULTURE.

From February onwards it sends up its dainty bell-shaped flowers of a beautiful shade of pink, which continue to appear over a long period.

The specific name "uniflora" is rather a misnomer, as the flowers are not solitary, but often appear two or three together on the same stem.

The ease with which it roots at the joints suggests an easy means of increase, and cuttings will root readily almost at any time of the year.—DUNHEVED.

AN ATTRACTIVE AND NATURAL WAY OF GROWING MAIDENHAIR FERNS IN THE GREENHOUSE.

Maidenhair Ferns at their Best.

A MAIDENHAIR fern in a pot is not always in the happiest of conditions. However well cared for, there is a tendency to deterioration. For one thing, the continual cutting away of dead fronds as the plant gets older gives the fern a very dilapidated appearance, unless the fronds have grown luxuriantly enough to hide the fact. Maidenhairs in pots are also difficult to manage, and even under the best of treatment they will fade and die through various causes. Of course, maidenhair ferns can be grown wonderfully well in pots, and will attain a good age and splendid dimensions; but this happens, as a rule, in a temperature and atmosphere that few of us can afford to give and maintain.

The maidenhair fern, as a pot plant for either greenhouse or home decoration, is best while young, and a renewal as the plant advances is advisable. A well potted plant will continue in good condition for years in suitable surroundings, but a plant that has to be subjected to varying temperatures, perhaps extremes, vitiated or very dry atmospheres,

Digitized by Google

and possibly a certain amount of neglect, is sure to droop and die eventually.

A practical method of overcoming these disabilities, where the glasshouse is concerned, is to give these ferns plenty of scope for development. This can be done in any glass structure by means of establishing a fern rockery, into the interior of which the fern roots can find a congenial run and the fronds can be suspended with a current of warm air around them.

It is an easy matter to construct such a rockery in a corner of the smallest greenhouse. It can be a huge block of cement, with the necessary large pockets for the plants; and the block can be hollow and filled with soil. Maidenhair and other ferns and foliage plants can be planted on this "rockery," and in a short space of time the rockwork will be clothed with an exquisite mass of greenery, the white "rock" peeping out here and there. The effect is charming, and even on the smallest scale is sure to give unbounded delight to all who see it.

The advantages are that the plants, growing naturally unrestricted, cast their old fronds naturally also, and so make room for the young fronds to take their place. There is always plenty of foliage to be cut without destroying the artistic appearance of the ferns. Little attention is required beyond the provision of sufficient warmth, ample syringing of foliage and a constant supply of moisture to the roots.—H. A.

A Good Greenhouse Plant in Flower Now.

LIBONIA FLORIBUNDA is now at its best. One seldom sees it to-day, but it is well worth growing, for I know of no other plant just at this season of short dull days giving the cheery, bi-coloured, tubular flowers of scarlet and yellow. True the blooms are not big individually, but they are freely produced and a few well flowered specimens in 5in. pots make a pleasing change from the gay chrysanthemum and the customary forced bulbs of this period.

The libonia is not a difficult subject to grow, and, requiring but little warmth, it should prove a useful plant for those whose facilities to do with heating are not great. Cuttings are put in in April to May and if but few plants are required a sufficient strike can be obtained by inserting three cuttings around the rim of a 4in. pot filled with sandy soil. To aid quick root action, stand the latter pots in an 8in. pot, cover with glass, shade from sun and give a sprinkling of water as required. When well rooted, pot the plants singly into similar pots as rooted in or, if large specimens are preferred, do not disturb, but transfer wholly to pots 5½ins. in diameter. During summer grow coolly in frame or greenhouse and keep the foliage clean by occasional syringing. In winter the libonia will be safe so long as the frost is quite excluded with a minimum of pipe heat.

Something of a mystery surrounds the name of this plant, which, perchance, the Editor or some other authority can make clear. It is no longer called libonia, but jacobinia. An early edition of Johnson gives the name L. floribunda, but a later edition calls the plant Jacobinia pauciflora. This latter varietal name is a misnomer, for our subject is very free in flowering. And again, in Thompson's "Assistant," 1901 edition, libonias are called justicias, yet out of a list of over forty varieties of this latter plant, no mention is made of L. floribunda.—C. TURNER.

Sowing Seeds Under Glass.

SEED-SOWING is an operation that calls for the greatest care and attention to details, especially when seeds are sown under glass. In the latter case the greatest error that can be committed is that of sowing too thickly. Under glass the moment the young shoot shows above the soil it is subjected to a "drawing" influence, and when the seeds are sown thickly the plants are ruined before they are large enough to be thinned out or transplanted.

The sole remedy for such a state of things—or rather a preventive—is to sow seeds thinly over a wide surface, such as is afforded by a pan or box, and to place the pan or box very close up to glass immediately the shoots show through the soil. Even should this be impossible, the young plants will suffer but little if the seeds are sown wide apart

CONCRETE, AND ITS USES IN THE GARDEN

This article describes an economical method of path-making which can be carried out by anyone if the practical details given here are followed.

CONCRETE has evidently come to stay, and its uses in industry are increasing every year; on account of its great strength and durability it is frequently used to replace other more expensive materials. In the making of concete slabs, similar to those on the garden path in the accompanying illustration, no great skill is required, providing the material used is clean, is mixed in proper proportions, and allowed adequate time to dry. A good formula for these slabs is: 1 part Portland cement, 2 parts sharp sand, 1 part cinder ash, and 1 part broken brick or stone (not larger than ½in.), which should be thoroughly mixed dry, being turned three times, and again when the water is added. For suitable moulds, if medium-sized slabs are required, the shallow margarine boxes, about 2½ins. deep, obtainable from the grocer's are quite good and inexpensive. It is best to have about six such moulds and to measure out just enough dry concrete to fill them all at one gauge: that is, assuming that they are being made in one's spare time.

As a guide to the time they take to make, I might add that I did not to have to exert myself unduly to complete six slabs in an hour.

After the concrete slab has stood for twenty-four hours, if made properly it should be set enough to stand being knocked out of the mould to dry; it is advisable, however, to grease or oil the interior of the mould, more especially the sides, before filling with concrete, to prevent the mixture from adhering to the wood; if any old iron rod is available or even wire netting, this can be inserted about the centre as reinforcement, but it is not absolutely necessary for garden paths, as they stand quite well if it is omitted altogether, providing the concrete is of good quality. One should be careful to keep anything in the nature of clay or loamy material away from the mixing operations, otherwise failure will result. It is not advisable to start laying the slabs until they are thoroughly hard and dry. Ordinary sifted garden soil is all that is required to bed them on; keep rather a wide joint between the blocks by inserting a slip of wood, say ½in. thick, and simply grout them in with soil. The actual method of laying is, of course, a matter of taste, but if every alternate slab is reversed quite a good effect is produced.

CONCRETE SLABS MAKE A USEFUL GARDEN PATH.
They are inexpensive to make and require no upkeep.

The initial cost of such a path is small, and the upkeep nil; and for a new garden it is especially good, no clinker or hard-core being necessary for drainage, as would be needed for an ordinary gravel path, the slabs being laid down direct on the ground, simply levelled and made firm by treading. Another advantage is that they are easily moved if alterations are being made at any future time; and, above all, you always have a dry path to walk on however bad the weather is.

A rockery border edging can also be made cheaply in concrete, by using moulds about 30ins. long, 6ins. deep and 3ins. thick at the top edge, tapering to 2½ins. at the bottom. This enables it to turn out of the box easily. To give the desired effect, some of the larger pieces of clean stone or flint should be reserved for placing in the top edge while the concrete is still wet. A ½in. hole should be made in each end of the mould and a short piece of metal inserted. A corresponding hole is thus formed in the finished block, and is needful in connecting the different lengths together in the border edging, either straight or otherwise, by means of a piece of iron rod, which then keeps the whole lot in position. By reversing the blocks with the rusticated part now to the front and using three or more layers with the vertical joints broken as in brickwork, quite a good retaining wall can be built at a minimum cost.

GEO. W. HALL.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Tuberous Begonias in the Greenhouse.

Upon re-starting tuberous begonias into growth early in February, remove the tubers from their pots and, instead of filling trays with fresh loam, leaf-soil or peat, use the old soil in which they were grown. It will be found that this is full of dead root-fibre, which proves a most excellent starting medium. It encourages shy starters to break more readily and growth is invariably more vigorous and healthy than if fresh soil or fibre is used. A dash of flowers of sulphur added to the old soil is a precaution against mite. —C. C.

How to Obtain Earlier Potatoes.

To obtain an earlier supply of potatoes the following will be found very useful: Before putting tubers up to sprout, place a layer of dry, riddled ashes to a depth of 1in. in the boxes or trays, placing tubers as is usual. The ashes should be moistened, allowing the part which is resting on the ashes to become rooted. Under ordinary circumstances the tubers would not be rooted until a fortnight or so after planting. Care should be taken when removing for planting not to pull off any of the roots. A good soaking of the ashes will prevent any fear of loss in that respect. Should the tops appear when frost is expected, straw should be placed over them at night, taking it off in the morning and placing it in the rows ready for use again.—W. M.

Softening Hard Hands.

After handling soil during potting operations the hands become hard. The following hint will be most useful to those who find gloves impede the progress of potting: When washing the hands, pour a tablespoonful of ordinary paraffin into the water. This will soften the skin, removing the objectionable hard feeling.—T. H. H.

Chrysanthemum Cuttings.

Make up a compost of two parts good loam to half part of leaf-mould and one part sand. Put loam and leaf-mould through an ½in. sieve and sand through a ¼in. sieve. Mix this thoroughly and fill cutting box to within ½in. of top after putting a layer of coarse leaves over bottom of box. Cover this with a good layer of sand, and water if too dry. I generally use boxes 2ft. by 1ft. 3ins. and 4ins. deep. Take stiff stocky shoots about 3ins. long, coming direct from soil of old stools. Remove carefully with a sharp knife and have pieces of paper to name varieties as taken. Trim cuttings and cut stem squarely across immediately below joint with sharp knife so as to prevent bruising. Insert cuttings in box with unsharpened end of pencil and label as varieties are put in. I get sixty cuttings in a box on an average. Water and put on shelf in greenhouse with a temperature about 50°. Now take cutting box same size and remove bottom, put this over cuttings and cover with a piece of glass. Keep fairly close for a few days and turn glass every morning to remove condensed moisture. Gradually increase air until the glass can be removed altogether. Cuttings root in about three weeks. Never put cuttings in boxes where wood is not well seasoned, as I note results are disappointing, which must be caused by sap in wood. I always get a good percentage of strikes by this metohd.—W. J. B.

A Novel Method of Staking Perennials:

Before growth begins, lay a piece of wire netting of the same size on top of the clump. A month later fix a stake, about 6ins. shorter than the plants grow in height, firmly right in centre of clump. As the stalks force their way upwards through the openings "wriggle" up the wire netting part way. The branches and leaves prevent it from slipping back. Repeat from time to time until the wire is about three parts of the way up the full growth. The centre stick prevents the plants being blown sideways by the wind, and all the flowers are beautifully spaced by the wire openings. Neither heavy rain nor wind will destroy the regular and natural appearance of the plants.—J. T. M.

A Good Kneeling Pad.

At this time of year a gardener is constantly in need of a kneeling pad. May I suggest that a very good substitute for a more expensive one can be made with a piece of old motor tyre, by cutting off the outer rim, which can be done with a small sharp saw. A piece 16ins. long will make two good pads. Holes can be punched into it at each end with a cold chisel, and tapes or string adjusted for tying round the knee. This makes an inexpensive and thoroughly waterproof pad.—W. H. D.

A Ready Supply of Baked, Weed-free Soil for the Seed-boxes.

When raising plants from seed, trouble is always experienced, in a greater or lesser degree, from the weed seeds that lurk in the potting soil. The use of baked soil is the only absolute safeguard; but the baking of soil, even in the limited quantities needed for the operations of a small garden, is both a tedious and difficult business. The kitchen oven is seldom available, is limited in its capacity, and, moreover, this method does not usually find favour with the cook. The following plan is highly recommended as offering an ample supply of baked soil with an absolute minimum of trouble: When the periodical garden bonfire happens to be a big one and is burning in good heart, place half a barrowful of turves in and around the hottest parts, or bank the whole fire down with them as soon as there is plenty of heat inside. As the fire is worked to a finish the turf will break up and mix with the hot ashes, and the soil it contains will be thoroughly baked. The resultant diluted mixture of soil and ash, put through a fine riddle and mixed with clean sand or grit, as required, forms a most excellent weed-free and stimulating mixture for filling into the top 2ins. of pots and seed-boxes. —H. L. S.

HOW TO TAKE CUTTINGS OF BEDDING PLANTS

This article emphasises the value of sand as a propagating medium. Judging by the experience of our contributor, this is a method to be followed by all amateurs who desire to increase their stock of bedding plants easily and quickly.

I HAVE frequently advised that pure sand be used for many purposes of propagation, but never until last year have I used it to such an extent. I may say that I am now more than ever convinced that it is a good method of propagating a great many kinds of plants. During last year I had to fill some large beds in a large design with bedding plants, the number of plants used being in the vicinity of 10,000. As I only took over the work in late October, when not a cutting of any kind was put in, it may be imagined that I had to hurry things along. In the matter of bedding pelargoniums I was able to get a lot potted so as to provide cuttings in the spring. The same was done with ivy-leaved pelargoniums. By rooting these cuttings in the spring in sand I was able to get sufficient for the purpose. The ivy-leaved pelargoniums were put into sand in the propagator and did well, but with the cuttings of Paul Crampel I found that when they were set close together in the propagating frame they lost too many of their leaves. But this did not make me lose faith in the value of sand, for I filled some 5in. pots with sand and rooted the cuttings in these, the watering being done by dipping the pots in water. In this way they were rooted in a much quicker time than were some which were put in soil in the usual way. It is generally supposed that cuttings of geraniums are best not put in a propagator.

How to Proceed.

The sand used for propagation was from a local pit, and was fairly sharp and clean. It was passed through a sieve made with the perforated zinc as used for meat safes. The propagator consisted of two planks set at about 15ins. apart on the staging, with pieces nailed to the ends to keep them in place and form an enclosure. In the bottom was placed a layer of leaves, and this was surmounted by a layer of the sand about 4ins. in depth. The sand was levelled and pressed firmly, and then watered through a rosed can. When the water had drained away the prepared cuttings were pressed into the wet sand to the required depth. Often all the cuttings had been thus pressed into the sand another watering was given for the purpose of washing the sand close up to the stems. No other kind of firming was given. When the foliage had dried somewhat the covers were put on. These consisted merely of loose sheets of glass. The advantage of this arrangement is that there is no need to wipe the moisture-laden surface, but merely to reverse the glasses as the inner surface becomes beaded with moisture. There is less danger from damping or over-watering in the sand propagator, and when the cuttings have rooted they may be removed without the loss of a single root. Over and above this there is no need to make up fresh soil every time more cuttings are put in. All that should be done is to level the sand, water it again, and then put the cuttings in.

Hints on Treatment.

One hint I would like to give: that is not to have too shallow a depth of sand, and not to allow the cuttings to remain in the propagator long after they are rooted. If this is done the layer of leaves at the bottom is disturbed

Digitized by Google

when the cuttings are removed, and are then in the way of pressing the cuttings in. Those cuttings which are too soft in the stem to admit of their being pressed into the sand are put in by making a hole with a penknife, and pressing the sand back again. There is no need to be particular about this as the watering after insertion will ensure close contact of the sand with the stems.

A New Method of Striking Heliotrope.

It may interest readers to know that I wanted to make two large beds of heliotrope, each of which would need 500 plants. In February I had not a single cutting, but was able to get 100 from a friend. These were put into the warm propagator and in ten days they were rooted sufficiently to be boxed up. I left them for ten days and then took out the tops for further cuttings. Here I took the risk of taking them as internode cuttings, merely snipping them off above the leaf-joints with a pair of pocket scissors. The cuttings were not jointed, and no leaves were removed. They were merely snipped off and pressed into the wet sand. These also were rooted in ten days, and I was then able to put in another batch of cuttings from the the first plants. I continued in this way, removing some from the propagator and putting other cuttings in throughout the season till at bedding time I had 1,200 well rooted plants to set out.

Cuttings Without Joints.

I think that this question of taking cuttings without jointing them, needs a little investigation. I have found that there are many cuttings which will root as well when they are cut above as they will when they are cut below a joint. That is the case with Nepeta Mussinii. Last spring I needed 1,000 of these as young plants, and cut the young growths from the plants in the border in late February. Instead of first of all cutting these below a joint with a knife, and then in two cuts, removing the lower leaves, I snipped the tops off just above a joint with the scissors, thus making one cut instead of three. The cuttings rooted with scarcely a single loss. Other cuttings which I have tried as internode cuttings are Verbena venosa, antirrhinums, nasturtiums, tomatoes and bedding begonias of the fibrous type.

Raising Antirrhinums in Large Quantities.

In the matter of antirrhinums I would like to record an interesting experiment which I was compelled by necessity to make. I needed about 4,000 antirrhinums, and sowed the seeds accordingly, but found at the time of pricking them off that I had not sufficient. That meant either that I had to sow some more and risk their being late or worse still, to change my plans. I had found that heliotrope and nepeta would root well from internode cuttings, so why not antirrhinums also? Those of the pricked off antirrhinums which had sufficient length of stem were tried. I put in about twenty cuttings, which were mere tops with the bunch of small leaves at the top, cutting them just above the lowest pair of leaves so that there would be an opportunity of their breaking out from these leaves. In about a week I found that some of these cuttings were throwing out roots in the sand, so I at once took the tops off 1,000 seedlings and dibbled them into a propagator. Practically all of these rooted well, the older plants threw out growths, and I kept these plants which were rooted from the seedlings together so that I could form two beds of them. They flowered quite well, and if there was any difference in the quantity of flowers, it was in favour of the tops which were rooted. This hint may be useful to anyone who at a late date finds that he has not enough plants to fill the required space.

Now my chief point is that the propagation of soft-wooded plants can be done more quickly, and more economically, by using sand as a medium than in the older way of putting them in sandy soil. Just think of the difference in procedure. With soil you have to prepare the various ingredients, mix them, fill the pots, after cleaning and draining them. Then you have to secure the cuttings, joint them, remove the lower leaves, make a hole with the dibber, and firm each cutting. In my way you have to prepare the sand only for the first lot of cuttings, for the same sand serves throughout the season. Then you water it, snip off the cuttings with the scissors, press them into the wet sand, and water again. Of course, I do not say that it is better in all cases to use internode cuttings, but there are many plants which respond to this treatment, and it would be worth while for gardeners to experiment in that direction. W. F. R.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Clematis for Pillars.

I have three climbing roses on pillars on my lawn. They are American Pillar, Albéric Barbier and Paul's Scarlet Climber. I want to plant three large-flowered clematis to grow up with and among them. As I am away all August and September, I want these to flower before I go and after I come back. The colours should harmonise with the roses. What do you suggest? The soil is loamy clay.—C. M., Hampstead.

We suggest that you plant the following varieties of clematis to grow among your roses: Clematis Duchess of Edinburgh with Paul's Scarlet Climber, Clematis Henryi with American Pillar, and Clematis Lady Northcliffe with Albéric Barbier.

Canker on Fruit Trees.

I am enclosing a few apple twigs showing a peculiar scab or trouble of some sort on the bark. This has been spreading on my trees during the last one or two years and although I spray ½ gallon blue vitrol and one handful of lime to six or seven gallons of water, winter and summer, I cannot clear the trees. This spray seems to check the disease, but not to eradicate or prevent it spreading. The new shoots on the trees, apple and pear, grow away healthy at first, then the leaves turn yellow and the whole shoot either checks or dies off.—R. E. G., Melksham.

The shoots that you send are attacked by the canker disease. This is a contagious disease and spreads rapidly each season, from branch to branch and tree to tree. Spraying offers no means of controlling canker, the only remedy for which is to cut out and burn every scrap of diseased wood. This may seem—and is—drastic treatment, but it is the only way to get rid of the trouble. If you have a particular tree which is very badly infested, we should advise you to grub and burn it straight away, for it can only prove a fertile source of further trouble while it remains. We might mention that the home-made wash you have been using is likely to prove of little use against any disease or pest, applied in winter or summer. Fruit tree washes must be prepared with scientific accuracy to prove efficacious, and particularly is this so where fungicides are concerned.

Pruning Newly-planted Apples.

I purchased two half standard apples (James Grieve and Cox's Pomona) in September last. They are four years old and the nurseryman told me he would prune them before delivery. I received and planted them in early November. I doubt if they have been pruned, as all the growths are about 2ft. in length and are rather numerous. Would you kindly inform me if and how I should prune (I have heard that horizontal branches should be cut out)? Should I put grease bands round both trees and stakes? Would you also let me know if I may expect any fruit this year?—H. A. R., New Malden.

The two newly planted half standard apple trees should certainly be pruned, the best time for the work being February. At four years old the main branches should have developed and the pruning now required will be to shorten the leading or extension shoot of each branch by about half, and to cut back all side shoots on the branches, along with shoots that crowd the tree centre, to two bottom buds. You should have no difficulty in telling whether or no the nurseryman has pruned the trees. If he has, the cut surfaces terminating each shoot will be apparent; whereas, if unpruned, the shoot will be terminated by a bud. There is no need to remove horizontal branches. Your aim must be to establish four or five main branches, these being evenly spaced round the top of the stem so that the tree is well balanced. Then, the leading shoot on each branch is cut by half and all other side growths—unwanted as branches—cut hard back to two buds.

It is late in the season to apply grease bands, but it is still worth while doing so, for there are many egg-laying moths yet to attempt the long climb from the ground to the branches. As the trees are half standard they should certainly be staked at once. Regarding fruit, you must not expect any crop next summer, for the tree must be encouraged to make strong growth and a sound framework of sturdy branches before ever fruit is borne.

When to Apply Lawn Sand.

Can lawn sand be applied to daisies in dull weather, or does it require bright sunlight to be effective?—D. C. P., Felsted, Essex.

It is, on the whole, better to apply lawn sand, or any similar weed eradicator, in dry and bright weather. These eradicators are more effective when used under these conditions. It is generally advisable to divide the lawn into strips by means of pegs and string. This ensures that every part of the lawn is covered.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2880 Saturday, February 12th. 1927 Price TWOPENCE

TUBEROUS-ROOTED BEGONIAS are among the most decorative of our Summer-Flowering Greenhouse Plants, providing, as they do, a feast of blooms from May until September. The above picture is a reproduction of a natural colour photograph showing a house of the modern named Double and Basket varieties in the Nurseries of Blackmore & Langdon, Bath. This collection has a world-wide reputation and for many years has been given the highest awards at all the principal exhibitions in Great Britain. They are noted for their wonderful form and a wide range of colour combined with vigorous growth.

Write for descriptive Catalogue of above which also contains particulars of our renowned
Basket Begonias, Gloxinias, Delphiniums, Phlox, Cyclamen, etc.

THE GARDEN

VOL. XCI.—No. 2880. FEBRUARY 12, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Spring Planting.

IT seems appropriate to commence a spring number with a few notes on spring planting, although it is natural that the seed list is the most important factor in the gardeners' diary during the first three or four months of the year. It is difficult to discover how the very prevalent idea that planting can only be carried out in autumn has arisen, unless it be that gardening books and periodicals lay more stress on autumn planting than on spring. This idea, which almost amounts to a fetish with many keen gardeners, is entirely erroneous. Planting can be done at any time during the winter up to the end of March, provided the weather remains open and soil conditions permit, except in the case of many small plants, like strawberries and a few bulbous plants. But the list of the latter is small and for all practical purposes can be ignored. It may be taken as a golden rule that spring planting is as good, if not better, than autumn planting, as long as an observant eye is kept on the weather. The plants settle just as well into their places in the bed or border if planted in spring as at any other time, unless the season be particularly bad. It is not always the season that is at fault. The majority of failures can be put down to hasty and careless planting, in the hurry to get the work done. It is most important to plant carefully in order to give the plants every chance of survival.

It follows that since February and March are the months to carry out the necessary overhauling and replenishing of the rock garden, which simply contains miniatures of other plants in the garden, the early spring is not too late to plant up or fill the gaps in the herbaceous or shrubbery border. If the border was dug over in the autumn and planting had to be withheld owing to the heavy rains of November and to the recent frosts, so much the better for the soil and the plants now. This period of rest will do a great deal of good, for frost, wind and rain are decidedly beneficial to all soils. On the whole, too, the plants have a better chance of establishing themselves if planted during the next few weeks. They will soon be on the move, and once root activity commences the roots will readily take hold of the soil. The only point necessary is to take every precaution against a period of sunny weather accompanied by drying winds, which is common in spring, and keep the soil and the roots of the plants as moist as possible without being waterlogged.

Spring planting is necessary in all cases where pot plants are purchased, as it is unwise to consign a plant which has spent its early years in a pot to the mercy of an uncertain winter in the open ground. The pot is more suggestive of a rubus than a rose, plant responds much more readily to spring planting and has certainly a better chance of success.

Most of our plants are more elastic in nature than is generally supposed and provided they are properly handled and treated, they will respond as much to one period of planting as another. Be careful with the actual planting. Do not hurry over the work and at the same time expect good results. Finally, let your gardening knowledge and practical technique be guided by a little common sense, which is just as useful in gardening as it is with anything else.

A Rose Discovery.

DURING the past season an important development has taken place in the evolution of the rose, which may lead to the creation of a new and interesting race. It is too early yet to write definitely of the results accomplished by the art of the hybridist, but our representative in Scotland is now in a position to publish the essential facts for the first time.

Some time ago, Mr. Reginald Farrer discovered in China an unidentified rose species which is unlike any other in cultivation. Perhaps the most distinguishing feature about this novelty is the small, narrow-shaped leaflets and the dense distribution of spines on the wood. The appearance of the foliage while the wine red colour of the leafage provides a pretty setting for the myriads of white flowers whose pleasing effect is accentuated by their yellow centre.

The blooms are produced in massive trusses containing from fifty to eighty individual flowers that are conspicuous for their strong, delicious scent, quite distinct from the fragrance that is to be found in other roses. Another good point in favour of this novelty is its immunity to mildew; and as an example of its strong climbing habit it may be mentioned that the leading stems measure several yards in length and extend up the side of the glasshouse, along the roof to within a few inches of the apex. Some experts see in it a resemblance to the old musk rose Garland, but, be that as it may, the outstanding qualities which are outlined briefly hold out great possibilities to the hybridist.

This rare rose is in the possession of Messrs. Dobbie and Co., Edinburgh, who have used it as a parent. A number of crosses have been made with selected examples of the hybrid tea group, and herein lies the genesis of a new race. One has only to recall the popular hybrids obtained by crossing the Wichuraiana rose to recognise the possibilities of Nature's ample lap.

This Week's Work

Sow early peas and broad beans.

Sow cauliflower, onions and Brussel sprouts in boxes placed in a greenhouse.

Plant a few early potatoes on a warm south border.

Finish renovating the garden paths.

Fork over and lightly top-dress the herbaceous border.

Prepare ground for spring planting of perennials and shrubs.

Feed your lawn with a mixture of superphosphate, three parts, and sulphate of ammonia, one part.

Plant some Jerusalem artichokes.

Fill up all gaps in your rose beds with young healthy bushes.

A New Gaillardia.

A SEEDLING from Gaillardia grandiflora of a tangerine orange self, known as Tangerine provides a striking break in this useful border plant. The habit is identical with Gaillardia grandiflora, and the effective shade—which, being a self colour, permits of its use in colour schemes—is one which will be most attractive in the border, being entirely unrepresented by any similar free-flowering and hardy subject. It does not in any way perpetuate the rather garish shades of the majority of gaillardias, and will easily be the foremost variety in this class.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 11, which appeared in our issue of January 29 h, have been awarded to

Mrs. Manser,
4, Heath Grove,
Barming Heath, Maidstone.

and

Mr. F. T. Bradbury,
Rosewarne, Mawnan,
Near Falmouth.

To each of whom a cheque for that amount has been sent.

BEGONIAS for BEDDING and GREENHOUSE

BEGONIAS of to-day as produced by our British growers have no rivals in the course of flower evolution. No flower can boast of such reform as has been enacted in the begonia by our hybridists, and we should be proud of the fact that all the varieties introduced during the past twenty-five years, which means, in fact, all those named varieties which attract so much attention at our leading horticultural shows, have been produced in our own country. A comparatively few years ago the popular begonia possessed a flower similar in shape to our double hollyhock and a long stem which would almost commend it for use as a basket variety. These features have now been eliminated and we have in their stead beautifully formed rose-like flowers carried on stiff, upright stems, which need little or no support; beside which the flowers are now at least three times larger than their predecessors and the variety of colour has been increased amazingly.

A few of the new large-flowered varieties which should be in every grower's collection are Lord Lambourne, lovely shaded orange; Lucy V. Toner, old rose; Peace, cream; Mrs. J. S. Brunton, lilac rose; Hilda Langdon, pink (a real gem); Grand Monarch, deep crimson; Nurse Cavell, pure white; and Mrs. T. Crawford, salmon pink.

Many would-be growers of these improved begonias are deterred from doing so, thinking they require very special facilities and conveniences. This is a fallacy. Everyone having a greenhouse, whether heated or not, can possess a batch of these plants, which will give such a profusion of flowers for at least four months of the year as is provided by no other tuberous-rooted subjects.

As bedding plants, too, begonias are indispensable, thriving, as they will, in those shady corners of the garden where few other bedding plants are successful.

To grow begonias from seed, a heated greenhouse is essential if they are required to flower the same year. It is necessary to retain a temperature of 65° to 67°. The seed should be sown during January or February in well drained pots, using a compost containing equal proportions of well decayed loam and leaf-mould and a liberal sprinkling of sand. Place some of the rougher parts of the prepared soil over the crocks and fill to within half an inch of the rim of the pot, making the surface perfectly level by pressing lightly. Then water the soil, using a fine rose, sufficiently to saturate the whole, and leave the pots a few hours to drain before sowing.

The seed, which is among the smallest of our flower seeds, should be mixed with a pinch of fine silver sand, as this will ensure a more even distribution. Cover the pot with a piece of glass and place a sheet of paper over the whole. It is essential that the surface of the soil and seed be kept moist and heavily shaded until germination has taken place. The seedlings will appear in about ten to fourteen days, when they should be gradually exposed to the light and air to prevent them from becoming drawn. When the third leaf appears they should be pricked off into boxes about an inch apart, and in a month or six weeks' time these seedlings should have two or three leaves in addition to their seed leaves. They can then be transplanted into larger and deeper boxes and eventually either potted into 2½in. pots, if required for greenhouse work, or placed in a cold frame and gradually hardened off for bedding purposes. A similar procedure to this may be adopted in a cold house, but the sowing should not be made until April and there will be no time to transplant into the second box. Small tubers, however, will have formed, and these can be started the following spring and will produce strong plants.

Starting the Tubers.

The quickest and easiest method of getting plants is from tubers, which should be started during January or February in a heated house, or March or April if unheated. Boxes 2½ins. deep with a nice light soil consisting of one part each loam and leaf-mould and a half part coarse sand. The tubers should be just buried, and watering should be done sparingly until growth appears. When the shoots are an inch or so long, they can be potted into 4in. or 4½in. pots, using a compost similar to the above with a quarter part decayed manure added. As soon as the roots reach the sides of the pots they are ready for their final move into 6in., 7in. or 8in., according to the size and vigour of the plants, care being taken not to overpot. The soil for this should contain two parts fibrous loam, one part leaf-mould, sufficient sand to keep it open, half part well decayed manure, a sprinkling of soot, also a little bone flour or bone meal. Should any of the plants be showing flower-buds, these must be rigorously removed until they are thoroughly established, as only undeveloped flowers will otherwise be produced. The plants should be ready to flower about a month after potting, at which period a weak liquid manure may be given occasionally.

The atmosphere in the begonia house must always be kept moist by damping stages and floors, and the plants may be sprayed on bright mornings until they begin to flower. While begonias require all the light they can get, they should be protected from the direct rays of the sun. A rolling blind is the best method of shading the house, but if this is impracticable a thin permanent shading may be applied on the outside.

Begonias detest a sour soil, and the chief cause of this is overwatering. The soil must be on the dry side before more water is added. On no account coddle strong begonia plants, give all the light and air possible while avoiding direct sun and draughts.

For Bedding.

Tubers required for bedding purposes should be started in March or April in a

BEGONIA HILDA LANGDON, ONE OF THE MOST BEAUTIFUL OF MODERN VARIETIES.

A COLLECTION OF BEGONIAS IN AN AMATEUR'S GREENHOUSE.

Digitized by Google

manner similar to that recommended for pot culture, but instead of being potted they should be placed outside in a cold frame and gradually hardened off for planting out about the first week in June. The ground which is to receive them should have previously been well dug and manured, and the plants should be placed about 10ins. to 12ins. apart. Immediately after planting give them a good watering and then a mulching of either rotten manure, leaf-mould or coconut fibre. This will help to retain the moisture at their roots, which they so much require.

As with pot begonias, all flower-buds should be removed for a week or two after planting out, as this will give the plants a chance to make roots and foliage. A. G. L.

THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

THE planning of a garden to this house has not been an easy matter, on account of the unusually placed—and, from the garden designer's point of view, awkward—position of the block of offices projecting on the north, into what would normally be the main garden front. But, as the axial line of the house is not at a right angle with that of the greater part of the ground, this difficulty has been got over by enclosing a small space, which will be a pleasant little garden for the maids, square with the house, and then having the main flower garden, of octagonal form, agreeing with the different angle of the ground beyond. A planting of shrubs, mostly evergreen, surrounds this garden and the small one next the house. Box, yew, laurustinus and laurel give an ample choice for the background planting and for enclosing the seats, with smaller green shrubs such as skimmia, rosemary and the dwarf alpine rhododendrons for the places nearer the paths and immediately surrounding the four divisions for flowers in the angles. To the south and east are seats embowered in yew or box, with a western seat across the long path. To the north the middle path of the octagon leads out to the lawn. With flowers all round, the eight-sided grass plot will be a pleasant feature. It may be tempting to give it some central ornament—sundial, bird-bath or stone basket—but it will be none the worse, and will be more restful, if it has nothing to break its own quiet space. Below the lawn a hedge or trellis or rambling roses will make a good screen to the vegetable quarters. There is a bank sloping down away from the house on the west side, dying out to nothing when it comes even with the middle of the lawn. Beyond this, to the west, it is proposed to have a considerable width of flowering trees, and again at the back of this another belt of trees for shelter. A quantity of flowering trees may easily be planted so that very little good effect is gained; it is a matter that calls for some restraint and careful consideration. A lesser number, such as is shown on the plan, will be of much greater value in the garden landscape. Such a planting, with the addition of groups of silver-stemmed birches, with a general background of green hollies joining into Lawson's Cypress at the southern end, and red cedar, which is really a juniper, at the northern, will be much more effective.

On the west side of the long path next to the road, and including the slope of the bank, there should be a quiet planting of one kind of evergreen, preferably Portugal laurel; this will join into the taller group of Lawson's Cypress. Just beyond the western end of the house there will be a planting of bush lilacs; the square recess opposite will be a little garden of roses. Then more flowering shrubs on the bank side, with some evergreens, to balance the shrubs east of the path that encloses the octagonal garden. The same kind of shrub planting will follow beyond the seat and will continue to the beginning of the lawn. From that point onward there will be a flower border on each side, mainly of useful things for cutting. The group of gold privet, gold elder and laburnum will combine into a fine effect of yellow flower and foliage. Here will be an opportunity for the best display of the perfect blue of delphinium and anchusa in the border, for though, as a rule, the best effects are produced by groupings of plants in graduated harmonies, yet the pure blues demand the exceptional treatment of a distinct contrast. The patch of ground west of the garage with a partly rounded front will be a treasure to a careful cook. A lavender hedge, though not of kitchen use, will come well at the back. A fine clump of globe artichoke will handsomely fill the north-east angle; some tufts of the broad-leaved sorrel, so good for milk soups, will follow parallel with the lavender, then a patch of mint and one of sage, with thyme, savory and marjoram along the front edge, ending with tarragon in the warmest corner next to the privet hedge at the back. These various herbs when fully established will not only be of considerable decorative value in the garden but also of great use in the kitchen.

SPRING PLANTING OF ROSES

I AM often asked in January, "Is it too late to plant roses?" and invariably reply, "Certainly not. You may plant with every chance of success even up till April." I have had clients calling upon me and saying how successful had been these late-planted roses.

However, I do not advocate leaving the planting until April. It is much better to have the work done before the end of February. Personally, so long as the weather keeps open, I would rather plant now than I would during the terribly wet month of November, which everybody proclaims as the month for rose planting.

Conditions of soil should govern us more in the matter of planting than the actual date, providing we obtain dormant plants. For this purpose many growers offer retarded plants. When plants start into growth in spring, then there is more risk to their ultimate success than if quite dormant.

If one thing deterred me from spring planting more than any other, it would be the fear that I should not obtain the varieties I wanted. There is every sign that the most popular roses will be difficult to obtain presently, so I would counsel my readers to secure what they require now, and if they cannot plant at once, just heel in the plants in a trench, with the roots well covered with fine soil. It is often surprising to me that some people cannot understand that plants have perishable roots. They will leave plants for days in the package in which they arrive; whereas if the plants were unpacked, the roots placed for a time in a tub of water and then buried in soil, they would remain fresh and lively for weeks.

A very essential detail in all planting, but more especially in spring, is to have some good compost ready to place on the roots. A reliable mixture is old potting soil (sifted), leaf-soil, a little burnt garden refuse, and about half a peck of bone-meal to a bushel of the compost. Let these all be well mixed together, then, when about to plant, make a hole in the prepared bed of about 1ft. square, hold the rose bush in the centre of the hole, and work in among the roots a shovelful of this compost. After pressing this firm, fill up with the soil removed. If at all wet, this top soil need not be trodden too firm. Rather defer doing this until it is a little drier.

All roots of roses should be trimmed over before planting. The jagged ends cut off, and even if there are no jagged ends it is best just to cut the extreme ends, so that new roots have a good start.

If there is one thing I object to more than another, it is planting roses to fill up gaps in existing beds. I know this is often unavoidable, and if heavy rains follow see that the holes are free from stagnant water.

Wherever possible, dig up a fresh piece of soil for the roses. I am thinking now of the very tiny garden. Of course, some roses are wanted. It would not be a garden without a rose or two. Possibly it is a new garden with a border all round the side and a grass plot in the centre. You can cut out a bed in the turf about 6ft. in diameter and grow eight to twelve good roses. If you decide to have them in the borders, just start and trench these. It is not a long job and it pays to start well. Mark out a yard in length. Dig out the top spadeful and wheel it to the end of the border where the work will finish. Now shovel out the loose soil and also wheel away. You now take a strong fork and dig up the next layer of soil. After this is done, give a coating of manure and garden rubbish or Wakeleys Hop manure, which is an excellent substitute, and incorporate this with the already forked-up soil.

You now mark off another yard. Dig the top soil of this No. 2 trench and put it into No. 1 trench, and this latter is now complete.

If you can afford all the border for roses you will be well repaid; if not, plant half a dozen or a dozen bushes 2ft. apart each way.

Six fine varieties for the novice would be Mrs. John Laing, Hugh Dickson, Frau Karl Druschki, Caroline Testout, Mme. Butterfly and Independence Day. These would grow in any garden which is not overshaded by trees. If no manure can be procured, the bone-meal will give plants a good start, and a sprinkling of a good fertiliser, such as Clay's, during May and June, will be sufficient nourishment.

A BED OF THE HYBRID TEA ROSE CAROLINE TESTOUT.

If for any reason planting must be deferred till March, I advise pruning the plants back to 2ins. or 3ins. at time of planting. It sounds drastic, but it pays. Ramblers planted late are best cut back to about 12ins.; but climbing hybrid teas should not be pruned the first season.

But some of my readers may desire a somewhat larger selection, and I append a list of eighteen really reliable varieties: Hugh Dickson, Frau Karl Druschki, General McArthur, Betty Uprichard, Mme. Butterfly, Christine, Mme. Jules Bouché, Souvenir de Georges Pernet, Etoile de Hollande, Independence Day, Mrs. Wemyss Quin, Mrs. Henry Morse (susceptible to mildew), Miss Willmott, Los Angeles, Covent Garden, Shot Silk, Lady Pirrie and Clarice Goodacre.

It should be remembered that roses repay for being transplanted every two or three years. Supposing one has a bed with several blank spaces, I would advise that the existing plants be dug up, their roots trimmed back and the plants carefully heeled in. Now proceed to dig the bed two spades deep, working in some bone-meal as work proceeds, also old rotted manure if available. When all is finished, replant the older plants in the centre and fill up the bed with some or all of the varieties I have given. I once knew an eminents gardener who made it a practice to transplant one-third of his roses each year; thus the whole rose garden was replanted in three years, and with marked success. The transplanting affords the plants a new lease of life, and it can be carried out on a small scale as well as on a large one.

Of course, where plants have been established for some years then it would not be advisable to move them. WALTER EASLEA.

FLOWER GARDEN NOTES

A Rock Garden Pentstemon.

OF all the interesting and useful species of pentstemons which grow in the Rocky Mountains of Canada, P. cyananthus is one of the best. For planting in the herbaceous border or, better still, between large rocks in the rock garden this penstemon always attracts the attention it deserves. Growing from 3ft. to 4ft. high, its spikes of lovely blue flowers open in June and continue for a long period. It seems of quite easy culture, providing the site is sunny, the soil well drained and a fair amount of sharp sand added.

P. cyananthus can be raised from seed sown in the autumn, preferably as soon as it is ripe, also propagated by cuttings and struck in a cold frame. Like other species of pentstemons, P. cyananthus will sometimes die off in winter, although to all appearances in good health, therefore it is always wise to raise a few new plants every year.—R. MOORE.

The Blue Mountain Daisy.

ASTER ALPINUS, commonly known as the blue mountain daisy, is a delight on the rock garden and in the front of an ordinary flower border. It forms sturdy tufts about 6ins. high and the Michaelmas daisy shaped flowers are a pale blue, with a golden yellow centre. There are, however, a number of different forms and varieties—Elliott's variety being a grand plant, with large flowers, in every way an improvement on the type. Then we have albus for those who enjoy white flowers, roseus with lilac pink blooms, superbus deep violet blue, and Wargrave Pink. A choice form is subcœrulea, with rich violet flowers 2ins. across, the centre being deep orange. This plant

Digitized by Google

grows about 9ins. high. A. alpinus and its varieties present no difficulties in the way of cultivation, and they will succeed in a loamy soil where they escape the hot, midday sun.

They are quite hardy and are at their best about June. With ordinary care they soon increase, and in time it will be advisable to lift and divide them, such work being carried out in early autumn or spring, just before the roots become active. The spring is also a good time to purchase plants of this description and pot grown examples can often be obtained. The alpine aster is a gem that should be found on every rock garden, however small for a batch of healthy plants covered with daisy-like flowers, especially the blue varieties is a pleasing and attractive sight. Mice and slugs are particularly devoted to the young growths of A. alpinus, the former must be trapped and the latter are held at bay by a liberal sprinkling of sharp grit well worked in among the crowns.—T. W. B.

Saxifraga oppositifolia.

IT is interesting to observe that few writers agree regarding the treatment of this charming rockfoil, so it is evident that each grower must, to a large extent, discover what will suit the plant in his own particular locality and then act accordingly. However, a few remarks on S. oppositifolia and its varieties, together with a cultural hint or two, may not be amiss, and, moreover, they may act as a sign-post to many who try to grow and flower this delightful saxifrage and more or less fail in the attempt.

They are in flower, early in the year—February and March—fine examples being being covered with bloom in varying degrees of red. One of the brightest forms is known as splendens, which produces a wealth of its heather-purple flowers in March. Another distinct variety is the Italian latina, of a rosy purple hue; while pallida, as its name implies, is much paler in colour. The white one known as alba is free flowering, but somewhat starry in appearance, and perhaps W. A. Clark is the brightest of the set. Other varieties are quoted in catalogues, and there may be improvements on those mentioned above. S. oppositifolia is found in the Alps, the Pyrenees, in Scotland and in Yorkshire; the best varieties, however, hail from the first two places named.

So far, I have found no great difficulty in growing these rock foils, either in pots or pans or on the rock garden. At one time I had scores in the former receptacles plunged in ashes and sand, and it was remarkable how well they rooted in the sand. This, however, is not suggested as a rooting medium, but it shows that it could be added to the soil with advantage. A cold, heavy loam must be avoided, so a good compost would be of a medium texture with a little broken sandstone or limestone added.

A cool root run is the ideal, and positions ought to be chosen where the hot, dry sun of summer will have no bad effects.

No doubt, the principal secret of success is frequent propagation, and fine results are obtained from annual increase by division, or the second year from cuttings. The plants are divided immediately after flowering, and when planting it should be remembered that the growths form roots as they extend, and for this reason they must be set in the soil fairly deeply or failure will accrue. There may be large patches which will go another year, but these must receive attention by top-dressing with a gritty, limy compost. In dry weather water will be required occasionally, and where this treatment causes the foliage to brown, it would be as well to use rain-water only.

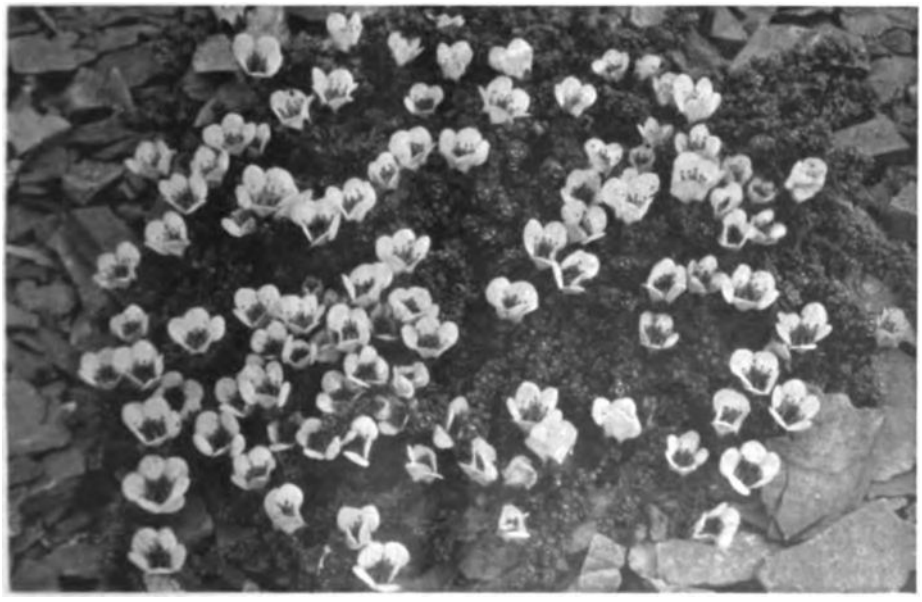
These rock foils form lovely carpets in the rock garden or moraine, and when smothered with bloom they are indeed glorious—particularly as they flower so early in the year. Slugs, for some reason, do not appear to be very fond of these exquisite saxifrages. —CHEPSTOW.

A Perennial with Handsome Foliage

A GROUP of plants well worthy of more attention than it receives is acanthus. Practically all the species have extremely fine foliage and a generally striking habit of growth which ensures a distinctive effect. Although the plants come from countries adjoining the Mediterranean, they seem to be quite hardy in Britain, for, even if the foliage is damaged, the roots do not suffer from frost. Acanthus is not a showy subject for the mixed border, as the flowers, although possessing a peculiar shade, are not gaily coloured. But all the species are well worth growing for their foliage alone. It is best to plant singly or in groups where the specimens can exhibit their true character. Acanthus is very accommodating in the matter of soil and it often succeeds well on poor ground, especially if this is on the light side. On heavy clay soils the results are not so good and in such positions the plants often refuse to flower altogether. Acanthus is a very handsome subject to plant on the turf of lawns and it may also be employed on rocky banks or similar situations. The plants will

THE HANDSOME FOLIAGE AND FLOWER SPIKES OF ACANTHUS LOOK WELL IN THE BORDER.

grow in fairly deep shade, but here they rarely flower and the foliage is usually less fine than in a more open position. The chief hardy species of acanthus include the following: AA. hirsutus, syriacus, mollis, spinosa, longifolius and spinosissimus. The plants vary from 1½ft. to 4ft. in height, according to soil and situation. When very favourably placed it is not an uncommon thing for an acanthus at flowering time to reach the height of 6ft. and such a specimen is about as handsome as anything one could see in the garden.—S. LEONARD BASTIN.



ONE OF THE BEST SAXIFRAGES, S. OPPOSITIFOLIA.

Time to Plant Ranunculi.

ONE of the finest sights in the garden is a bed or a border of ranunculi in full bloom. Various sorts of these plants are to be obtained in a great variety of shades and the roots are inexpensive. Light soil, which has been well manured and deeply dug suits the plants best. If the natural soil is very heavy and wholly unsuitable, it is worth taking it out to the depth of 2ft. and filling in the position with a mixture of two parts of loam and one each of leaf-mould, sharp sand and well decayed manure. The roots should be placed about 6ins. apart and covered with a couple of inches of fine soil. Often, a beginner will set his ranunculus roots upside down and it is worth pointing out that the "claws" should always be placed downwards, the crown being more or less flat. It is very helpful to bed each root in with a little sand before finally covering with soil. If the weather is dry when the ranunculus plants begin to grow, watering will be needed, but this should be done after the sun has left the bed.—L. B.

RENOVATING THE ROCK GARDEN

WITH the promise of spring in the near future, any work in the rock garden that was not carried out in the autumn can now be done. One of the most important items is that of replanting groups that have been long in one position and have become overcrowded, also have exhausted the soil in which they are growing. This applies only to the stronger-growing subjects, like primulas, violas, arabis and saxifrages of the megasea section. Other plants, like those of the Kabschia saxifrages, may be left for some years in the same position, their only requirements being an annual top-dressing. This top-dressing is very necessary for the majority of rock plants, as many plants, like some of the alpine primulas, have a tendency to form stems and grow away from the surface of the ground, resulting in a leggy appearance. If given a good top-dressing, fresh roots are formed higher up the stem, and thus the plants benefit to a great extent by this being periodically performed.

Mossy phloxes, androsaces, achilleas and similar carpeting plants should also have a like compost of fine soil, leaf-mould and sharp sand worked in between their prostrate stems. Where there is room between the plants the surface should first be cleared of all weeds, then stirred up with a hand fork to loosen the soil in order to sweeten it. Then the top-dressing may be added, taking care that all trailing stems and exposed roots are covered with the gritty soil. As well as providing fresh food for the plants, the top-dressing gives the rock garden a neat and finished appearance in readiness for the coming season. For lime-loving plants, which constitute the majority of the inhabitants of the rock garden, a little bone-meal added to the mixture will be found beneficial. For peat-loving plants like shortias and plants of the heath family, a peaty mixture must be used for top-dressing.

Transplanting.

Although autumn is the best time for replanting early spring-flowering plants, the majority of stronger-growing kinds that come into flower somewhat later may be attended to now during favourable weather. Pockets in which the soil has become sour and exhausted should be emptied, and re-filled with good gritty soil, taking care to put plenty of drainage in the bottom. The stronger-growing plants that show signs of having exhausted the soil in which they are growing should be taken up and placed on one side. Then the old soil can be taken out, afterwards filling up the hole with new soil. In re-planting, select the strongest clumps and divide them up into pieces, each containing two or three growing points, or crowns, according to the kind of plant being dealt with. See that there are plenty of good healthy roots attached to each piece before planting. In planting, give each plant room for future growth. The accompanying illustration of a primula before and after re-planting will give readers an idea as to how this work should be done. In place of the crowded appearance of the former, we have the newly planted plants spaced out, each having plenty of room in which to develop.

Plants Requiring Attention.

The following are some of the principal families that require more frequent attention in transplanting: Alyssum, campanula, dianthus, erodium, aster, primulas of the bog, or strong-growing japonica section, saxifrages of the megasea section, as well as the mossy kinds; aubrietias, iberis, geranium, viola and veronica. There are many other strong-growing rock plants not mentioned above, but the list will give some idea of the kind of plant that soon exhausts the soil in a pocket, and either requires feeding with manure or replanting in fresh soil. It often happens that a coarse-growing plant tends to overrun its smaller neighbour, so it is necessary for a close watch to be kept on all plants to see that the weaker ones get a fair chance. The stronger plant should be either periodically cut back, or removed entirely to a fresh place where it will have more room.

The Best Time for the Work.

Early spring is the time for filling up gaps in the rock garden. At this time one can see what plants have been killed during the winter, and steps should be taken at once to make good the groups that have suffered. Although the best time for planting is in the early spring, or early autumn, established plants in pots may be put out at any time, although not advisable in hot dry weather. Some plants, like the alpine primulas, are dependent upon the developed growth of one season for flowering in the spring following. Therefore, these should be replanted soon after flowering. Saxifrages also are best moved in the spring in order to become established and secure a season's growth before flowering. Campanulas, asters and such-like plants may be moved in early spring and will flower the same season.

Hints on Planting.

A most important point to remember in planting alpines is to plant firmly. In their native haunts many plants are usually found wedged between rocks, and even grow in crevices from which it is almost impossible to dislodge them. Therefore, the soil round about the plant must be made very solid by means of forcing in stones quite close to the tufts. Many failures with the rarer alpines are due to careless and loose planting, the roots being merely covered with soil and not pressed firm enough to enable the roots to take hold. Many alpine plants, like some of the Kabschia saxifrages, that form large tufts, develop brown patches in the centre. These should be dealt with by cutting out all the dead parts, and then giving it a mulching of a mixture of grit and leaf-mould worked well in between the growths. Where, however, the plant has got too bad for this remedy, it should be taken up, divided into small pieces, each with plenty of roots attached, and planted again firmly. Advantage should be taken to renew the soil at the same time.

It may have been noticed that some patches of plants did not flourish as they ought to have done during the past season. This may have been due to their not being planted in the right position, either too much sun, or too shady. Their requirements should be ascertained, and the plants put into positions where they get more sun or more shade as required. Plants like æthionema prefer a hot sunny ledge or crevice, while plants like the mossy saxifrages require more moisture in a half-shady situation.

When all this work has been carried out and the necessary labelling attended to, the rock garden can be cleaned up and left to produce its welcome display of bloom during the coming season. It will, however, be necessary to watch for weeds, and also for slugs, which are very fond of the rarer plants.—W. I.

THINNING AND REPLANTING OF A CROWDED PATCH OF PRIMULAS.

LILIES FOR THE AMATEUR

THE genus lilium includes some of the most beautiful plants for garden decoration, and to a certain extent vies with the rose in popularity; but, alas! unlike the rose, the majority are not so amenable to general cultivation. In fact, many of them are only for the specialist or enthusiastic amateur. Even then, with all the care and attention lavished on them, they prove difficult. This is not so surprising when we consider their wide geographical range and the varied conditions under which they grow in nature, nearly always associated with other plants, such as shrubs and grasses, the roots of which help to keep the soil in good mechanical condition. I am convinced that it is this lack of plant association under garden cultivation that accounts for so many failures with this beautiful race of plants and, indeed, many other bulbous plants.

Cultural Details.

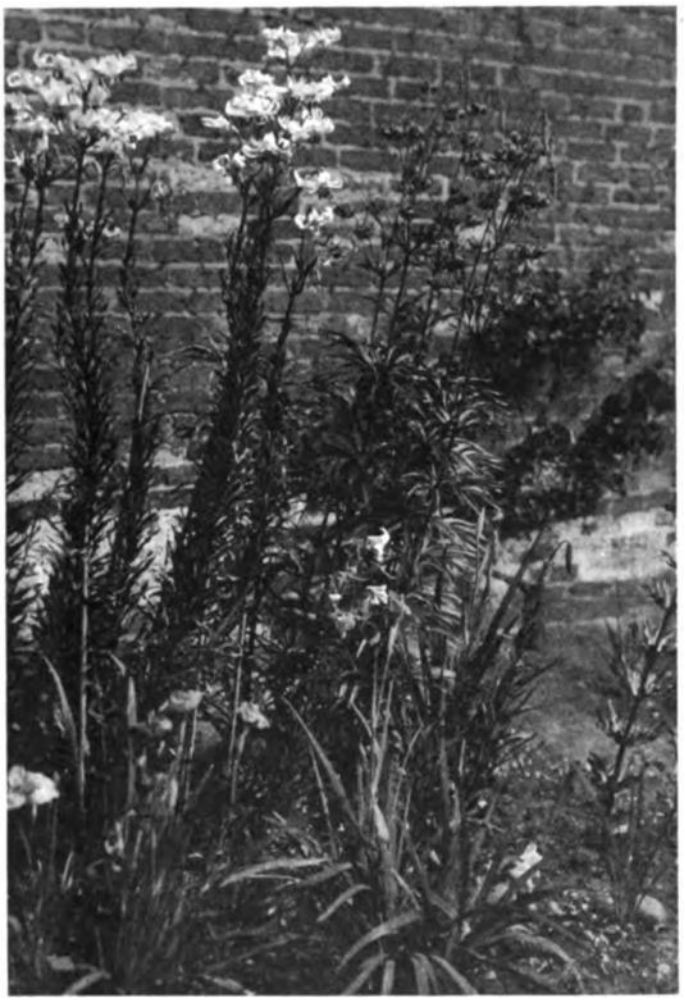
The first essential is to secure healthy bulbs. Having procured them, if they cannot be planted at once, they should be laid in boxes and covered with leaf-soil or fibre until such time as they can be dealt with, for lily bulbs quickly suffer if left exposed to the air for any length of time. With some of the choicer species it is a good plan to pot them up and keep them in a cold frame until better weather conditions prevail, when they may be planted out in sites previously prepared for them. Regarding the sites, there are quite a number of lilies that may be expected to succeed in any good medium well drained loam. And here let me say that the first essential to successful cultivation is sharp and perfect drainage. Especially is this necessary during the winter months, when wet, stagnant conditions at the root prove fatal to so many lilies, even to those species that enjoy ample moisture at the root during the growing season.

To ensure, at least to some extent, comfortable winter conditions at the root, it is a good plan to plant them among dwarf shrubs, the roots of which help to keep the ground in good condition. Even then, unless the soil conditions are ideal, it is wise to take out good holes at least 2ft. deep and put plenty of drainage in the bottom, filling the holes with prepared compost consisting of good loam, leaf-soil and sand. Do not spare plenty of gritty material—even a quantity of small stones—in the compost. Before planting, the fresh compost should be trodden fairly firm. When planting species with large bulbs, such as auratum and Henryi, they may be planted singly, but when dealing with smaller and choice species it is best to plant in colonies of three or even six bulbs. The larger bulbs should be planted at least 8ins. deep and the smaller ones not less than 4ins., remembering that the stem-rooting species should be planted deeper than the species that do not develop roots from the stem during the growing season.

The bulbs should be planted on and surrounded with plenty of clean coarse sand. This is of prime importance, and it is false economy to use it sparingly.

The sites should be marked with a neat stake, so that the young shoots when just coming through the ground may not be damaged by cultural operations.

Most liliums will stand all the sun they are likely to get in the British Isles, but most of them benefit by shade at the root. In planting them among dwarf shrubs and similar plants we, to a certain extent, provide them with good mechanical conditions at the root and also the essential shade at the root. Another important advantage of such a position is the fact that the bushes provide a certain amount of shelter during the spring, when the young shoots are apt to suffer from late spring frosts and cold cutting winds.



A CLUMP OF THE NANKEEN LILY (L. TESTACEUM).

Species that Succeed in Ordinary Loam.

All the following species and varieties may be expected to succeed in any well drained medium loam with the possible addition of some flaky leaf-soil, *viz.*: Lilium candidum.—This species requires different treatment from most of the others, for it should be planted or replanted during August, as it commences growth then; also, unlike most of them, it must not be planted deeply. The top of the bulbs should only be covered with 2ins. to 3ins. of soil, as this lily does best when the bulbs are exposed. Other species are croceum, the orange lily, tigrinum and its varieties Hansoni, regale, chalcedonicum, pomponium, monadelphum and its variety szovitsianum, Martagon and its varieties, album, dalmaticum and Catanii, also testaceum, elegans and its many varieties, umbellatum and Henryi, this last flourishing in heavy loam. LL. Willmottæ and tenuifolium also succeed under similar conditions. All the foregoing with the exception of L. tigrinum and its varieties, are—if not lime-lovers—indifferent to its presence. At the same time its presence does not seem necessary to them, although I feel sure that candidum is better for occasional dressings of lime or basic slag, the latter applied at the rate of 6 oz. to 8 oz. per square yard. It should be noted here that L. auratum and its varieties will not succeed in limy soils.

Species that Enjoy a Soil Rich in Humus.

All the following should do well in light medium loams with the addition of plenty of well decayed leaf-soil. This should be used in preference to peat, which when it gets into bad condition is very poisonous and is only safe when permeated with the fine roots of rhododendrons and similar shrubs. L. auratum and its varieties come into this group, also L. speciosum and its varieties. They are largely grown in pots and, except in the south and west, flower rather late for general outdoor cultivation. Like auratum, this lily dislikes lime. LL. rubellum and japonicum syn. Krameri, although I cannot say they are easy, are, however, so beautiful that they are worth a good deal of trouble. They enjoy a light loam with the addition of plenty of leaf-soil. There is quite a number of beautiful American lilies, but they are by no means easy under cultivation with the exception of L. pardalinum, the Californian panther lily, and its many varieties; while LL. superbum, parviflorum, parvum, philadelphicum, canadense, Grayi, Humboldtii var. magnificum and Parryi are all fairly easy in light loam with plenty of added leaf-soil. In common with most of the American lilies, they enjoy full sunshine with shade at the root.

Insect and Other Pests.

Considering the many cultural difficulties that attend the growing of lilies, they are singularly free from insect and other pests. Out of doors, especially on some soils, slugs are a real menace. Clean cultivation, plenty of sand round the bulbs and persistent trapping will do much to keep them in check, dry bran forming a very attractive bait for slugs. Mice eat lily bulbs, generally devoting their attention to the edible lilies of Japan, such as LL. rubellum, Leichtlinii, auratum and tigrinum.

Fungoid Diseases.

Botrytis cinerea, which attacks so many garden plants, often attacks lilies, especially L. candidum, late spring frosts and cold winds generally inducing attacks. On the first signs of attack the plants should be sprayed with liver of sulphur (sulphide of potassium), using 1 oz. to 3 gallons of water. If a little soft soap is dissolved with the mixture, it adheres much better to the foliage and is not so easily washed off.

THE BUSY MAN'S PAGE

Mulching Newly Planted Trees and Shrubs.

IT is advisable that all newly planted trees and shrubs, including fruit trees and also ornamental trees and shrubs, should receive a mulching of decayed manure at the present time. This applies whether they are autumn or spring planted. A mulch of this description neutralises to a large extent the bad effects liable to be caused as the result of drying winds which may prevail during the next few weeks. Trees and shrubs thus treated will also better resist spells of drought during the summer, and this is of especial benefit to trees planted on shallow soils or on soils resting on a very porous subsoil. If a mulching of manure is thought to be unsightly, a scattering of soil may be spread over its surface. Previous to applying the mulch make sure that each tree or shrub is securely fastened to its stake in such a manner that the bark cannot be injured and so that the ties cannot cut into the bark as it expands with growth.

Cinerarias from Off-Sets.

FROM a packet of mixed cineraria seeds it often happens that a plant with an exceptionally fine shade of colour or form of flower is among them. If the particular colour finds favour and has an attraction for the owner, he very naturally wishes to retain stock of it if possible. In some cases this may be successfully done by saving the seeds, but the flowers require protection from bees and various flies with a covering of gauze or fine muslin. Even though the flowers be protected, it does not always ensure their coming true to type.

The surest way to overcome the difficulty and perpetuate stock of a favourite plant is to increase it from off-sets taken from the old plant. During the flowering period great care should be observed when watering by keeping the pots in an evenly moist condition—never waterlogged or the other extreme. When the plant has finished flowering, cut it back to within a few inches of the pot. Encourage the plants to make side growths and off-sets by placing them in a position where they will not be exposed to much sunshine. A temperature of about 50° should be maintained, and the staging and surroundings kept somewhat damp in order to promote growth. When the off-sets have attained sufficient size, they should be pulled off with some roots attached and placed in 3in. pots. A compost of about equal parts of loam and decayed leaves passed through a ½in. sieve, with enough sand to keep it open, will do for the first potting. The plants may then be kept rather close for a few days until established. Afterwards their treatment should be similar to plants raised from seeds, potting them on into larger-sized pots as they require it. The plants should be labelled as a means of identification afterwards.

Potting Mixtures.

THE soil mixture which is used when potting naturally depends to a considerable extent on the plants which are to be grown. Professional gardeners will at times hold forth on the elaborate composts which they prepare, but, happily, most plants will be suited with one or other of about three comparatively simple mixtures. A good general potting mixture which will meet the needs of begonias, fuchsias, calceolarias, primulas, geraniums, cinerarias, carnations and by far the greater number of plants commonly grown is made in this way: To three parts of fibrous loam add one part of well crumbled manure, one part of leaf-mould and one-tenth part of sand, the whole being well mixed together.

Pot roses do best in a mixture of fibrous loam and well decayed manure in equal parts, to which is added a twelfth part of sharp sand.

Azaleas, heaths, hard-wooded plants generally, and also ferns and palms, should be potted in a soil which consists of two parts of peat, one part of loam and just a sprinkling of sand.

Garden Steps and Paths.

IT has become quite a common practice to make use of steps and paths about a garden and to plant them with dwarf and creeping subjects, and, so long as this is not done at the expense of thwarting the use of either steps or path, well and good. The illustration shows a judicious use of plants at the foot of steps and clinging to the sides, and is in keeping with the surroundings. With few exceptions, it will, I think, be found more satisfactory to raise plants from seed, sowing it thinly where wanted, rather than

LOW-GROWING PLANTS MAKE ATTRACTIVE DECORATION FOR PATHS AND STEPS.

to attempt the pressing into a confined space of young plants that have to be found root room. In this connection, one thinks of aubrietias, seeds of which can be sown in the crevices, aided by a little fine sandy soil; and Cerastium tomentosum, sweet alyssum, some of the dwarf campanulas, Erinus alpinus and saxifrages. In the case of flagged paths, while it may not be a difficult matter to put in young plants from pots between the spaces, on steps it is, generally speaking, better to make use of those raised from seed sown where they are wanted, and thinning out as need be.

Sowing Choice Flower Seeds.

THE growing of choice plants like begonias, cyclamen, primulas, cinerarias, etc., from seed is a simple matter, but it pays to give a little special care to secure the best results. Here are a few points worth bearing in mind. The seeds may be sown in boxes, pots or pans, and the mould, which should be a good potting compost, must be crumbled or sifted until it is very fine. Place the soil in the pot, or whatever the receptacle may be, not forgetting some drainage at the bottom. Arrange to have some fine, almost sand-like soil at the top, and moisten this slightly with warm water. Open the packet and shake the seed into the dry palm of the hand, then rubbing it very gently off with one finger so as to spread the thinnest possible layer over the soil. In the case of the tiny seeds of begonias and calceolarias it is just as well not to attempt to cover with soil at all. With other seeds sprinkle a thin layer of soil very lightly after sowing. The next step is to spread some damp moss over the seed-bed or, if this cannot be obtained, sheets of paper kept in a moist state may be employed. Examine in about two days, and if the surface soil seems dry sprinkle water on to the moss or the paper. Never water directly on to soil which has been sown with choice seeds. As soon as the little plants begin to appear remove the moss or paper and protect with a sheet of glass rested on the rim of the pot or box. For a few days shade the glass with brown paper, afterwards using white sheets. Do not forget to raise the glass a little for a few hours each day to admit air. When the seedlings are about half an inch high carefully prick them out at 2ins. apart into another pot. Remember that in some cases, and this is especially so with primulas, germination is rather irregular. Some of the last plants to appear may be a week or even ten days behind those that first put in an appearance. The first change into separate pots comes when the transplanted seedlings are just beginning to touch each other.

Clovers and Weeds on Lawns.

FEBRUARY is the best month in which to deal with lawns infested with clover and weeds. Of course, in the case of a lawn that has to sustain a great deal of wear a certain amount of clover is useful, but in ordinary cases the plant should be kept well in check, as it tends to kill the grass. Sulphate of ammonia is the best thing to employ for stopping clover and weed growth; this chemical will, at the same time, have a very stimulating effect on the grass plants. Where moss is prevalent sulphate of iron will soon eradicate the growth. A very excellent lawn sand which, while killing weeds, moss, etc., will help the grass to develop, is prepared in this way: Grind a quarter of a pound of sulphate of iron (green copperas) into powder; then add one pound of sulphate of ammonia, also well ground. Mix these two well together and blend thoroughly with 8lb. of fine sand of any kind. Those who live near the coast will find that sand from the beach answers the purpose very well. This dressing should be applied at the rate of 4 oz. to each square yard. In the case of big weeds it pays to place a pinch of the powder on the crown of each plant so as to ensure a speedy death. Where large weeds or considerable patches die there will naturally be a space left, and this must be returfed or sown with seed as soon as the weather becomes spring-like.

A Wallflower Hint.

WALLFLOWER plants that are of poor development and not as bushy as one would wish may be very much improved if treated in the following manner: Choose a mild day and then pinch back to the distance of about 2ins.; if the plants are small and stunted, 1in. will be sufficient. The result of this is the development of numerous side shoots, all of which head up for bloom. Sometimes the pinching back may make the wallflowers slightly later in coming into flower, but unless the spring is very late and cold the difference is hardly worth bothering about. In any case this method will ensure a large increase in the number of flowers actually produced.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Flowers for Small Gardens.

THE smaller the size of the garden, the greater the need for care in the choice of plants for succession of bloom. In the little garden illustrated here, a careful selection of plants gives a constant change of flowers from early spring until late autumn. The first necessity in a shut-in garden is to clothe the fences. Scarlet runner beans, which appear in the back of the border, are a good forerunner of more permanent climbers. String or stakes can be used as support for the beans. It is too early to sow, but no time should be lost in ordering seeds and preparing soil. As the digging is done for such a border, work in any organic manure, leaves, decayed vegetable matter, etc., and also 2oz. of lime and a handful of bone meal to each square yard. Borders by the side of fences often suffer from dryness, and to improve the supply of soil moisture, dig deeply, breaking up the subsoil thoroughly. Bulbs and early spring flowers were followed in the garden shown here by annuals, carnations, ten-week stocks, Madonna lilies and dahlias. The candytuft and virginian stock used as an edging were sown among crocus leaves, allowing these to die off naturally without becoming unsightly. A fine crop of tomatoes was also grown in the left border, showing how much more ingenuity can be exercised in the small garden than is needed in the garden of several acres.

Designing the Small Garden.

TASTES vary, and no hard and fast rules can be given for designing the tiny garden. Borders are generally best mixed, so that there shall be something in flower at each season of the year. They should run round the lawn; beds cut out of the lawn for special plants tend to diminish the apparent size of the garden. Shelter, shade and privacy are desirable on the lawn, and these can be obtained even in a small garden by the use of trellis work covered with climbing plants. Straight paths are best, and edged with suitable plants they can be made very attractive. Avoid useless ornaments. A stone vase filled with flowers, or a garden seat may be admitted, but garden statuary is only suitable for the large garden.

Planting Standard Roses.

ROSES must have fresh air. Anyone who has compared the foliage of a bush rose grown in a shut-in garden with that of a similar rose grown in a nursery field, will appreciate this point. Thick, closely grown, privet hedges and walled-in gardens are one of the biggest obstacles to rose culture in small gardens. I am particularly keen on the use of *standard* roses for this position. They hold their heads well above the boxed-in and stagnant air, and so thrive better than roses of the bush type. This is the best season for planting in towns, and a few hints may be useful to those who intend to grow roses for the first time.

When you see a single standard rose in a front garden, in nine cases out of ten you will find that it is perched on the top of a cone of parched soil. This is fatal. Roses must have a constant supply of water at the roots, and the little mounds in which many roses die a lingering death are dried out after a few hours of sunshine. *Keep the rose bed on the general level of the garden.*

Suppose you have ordered a few standard roses. They should arrive fresh, that is, the green parts of the stems should be firm, shiny and fresh looking. If not, they have been delayed in transit and are probably dried up. In such a case, lay the roses right into moist soil for a few days, after which they can be taken out and planted. Most nurserymen dip the roots in a prepared clay solution, which prevents loss of moisture.

If you are planting your roses in an old garden, *work up a little of the subsoil.* Never mind if it is a bit clayey, it will renovate the top layer. And, above all, break up the subsoil beneath your standard roses, and every year you will be glad of the extra work you put in preparing the site for it. Plant the rose firmly, spreading out the roots evenly. I find it best to stake the plants before filling in the soil. Use a strong stake, and do not tie too tightly. After planting, keep an eye open for strong winds. They loosen the stake and allow the plant to gyrate. This tears the delicate roots to shreds.

STANDARD ROSES ARE BEST FOR A SHUT-IN GARDEN.

THE EFFECTIVE TREATMENT OF A TINY GARDEN.

A few good varieties for present planting are Christine and Golden Emblem (yellow), K. of K. and Donald McDonald (red), Los Angeles, Mme. Edouard Herriot, Gorgeous and Independence Day (copper and flame colour), Lady Ashtown (pink), Ophelia and Pharisaer (rosy white).

WHAT to PLANT in the HERBACEOUS BORDER

Many of the varieties of perennials mentioned in this article are newcomers to the border, and all are worthy of being included in the planting schemes this month. The majority show considerable improvement both in colour and habit and in many ways are superior to the older forms.

A BORDER IN EARLY SUMMER.

This is the month when all renovation work should be carried out. All gaps in the herbaceous border may be filled now, and in the following list will be found plants which are useful for all parts of the border, some may be utilised in back row planting, others, again, for furnishing masses of colour in the front.

ALTHOUGH autumn is the best time for preparing the border and dividing and transplanting old, well established plants, the spring is certainly the best season in which to put in new plants, as they will then have the summer before them in which to make good, instead of being exposed to the perils of hard frost before their roots—rarely either strong or numerous in young stock—have had time to get hold of the ground. The choice of plants for a border depends, of course, on many things, including personal fancy; but there are some which are practically indispensable.

Delphiniums.

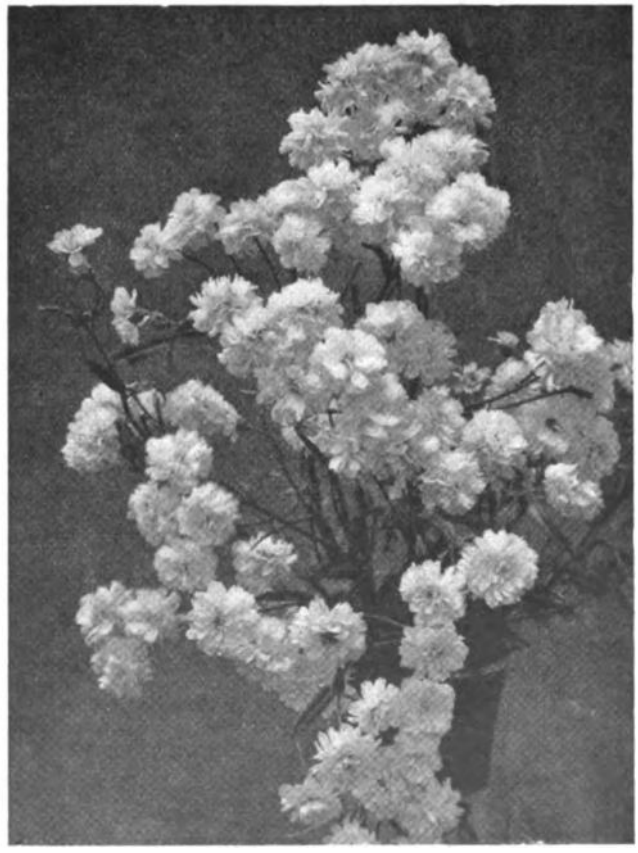
Of these, probably the finest of border plants, there are so many fine varieties that it is difficult to make a selection; but of the tall-growing kinds the following half-dozen will be found most satisfactory: Blue Boy, deep blue with a white eye, a variety with a gracefully tapering spike; Blue Bird, semi-double; Edward Bromet, an improved Rev. E. Lascelles; The Shah, a new and charming shade of rosy lavender; Blue Princess, sky blue; and Millicent Blackmore, blue shaded mauve. From the latter and the purple and blue Sir Douglas Haig, a fine new strain of delphiniums has been raised, known as the Wrexham or Hollyhock delphiniums. These are plants of taller stature, with a more tapering flower spike, which varies from 3ft. to 5ft. in height. In this strain there are many fine varieties, such as Monarch of Wales, illustrated on the front cover of THE GARDEN, September 25th, 1926. Purple Splendour, Joy Bells, and Coquette, all worthy of a place in the border by reason of their graceful habit and charming shades of blue, purple and pink. For the narrow border, Persimmon and other varieties of the dwarf Belladonna type are more suitable than the giants of 5ft., 6ft. or even 7ft. high. Kelway's Blue, Branching Persimmon and Lamartine are all good shades of light blue, and do not exceed 3ft. The perfectly satisfactory pure white delphinium has yet to make its appearance, but Beauty of Langport and Mrs. Christie Millar, both creamy white, are very pretty; and there is, of course, the old D. Moerheimii, a good white, but with unimposing spikes. It is a commendable plan to plant

Phlox decussata

immediately in front of the delphiniums, to screen them as far as possible in their ugly dying down stage. The phloxes can be grown in mixed colours, but the orange-scarlets must be separated from the pinks by the judicious interposition of whites and lilacs, otherwise the effect will be most discordant. Here is a list of a few of the most desirable varieties: Antonin Mercie, lavender and white, a very strong grower; Le Mahdi, reddish purple; Marvel, purple, less red than Le Mahdi; Baron van Dedem, orange scarlet; Coquelicot, vivid orange-scarlet—I do not find it a strong grower; General van Heutz, cerise-scarlet; Selma, soft pink; Rijnstroom, rose pink; Jules Cambon, deep rose; Baron van Heeckeren, salmon pink; Europa, pure white; E. A. Buchner, white flushed pink. Phloxes are easy of culture, but it should be remembered that they need ample supplies of water in a dry season, and that the orange scarlets are apt to "burn" under a strong sun.

The Torch Lilies

were, in the past, almost entirely grown on lawns or at the edge of shrubberies; but of late years the effectiveness in the border of their splendid red and yellow spikes has been recognised. Kniphofia Corallina and erecta are both good species, while among the best tall kniphofias are K. glaucescens



MANY HERBACEOUS FLOWERS ARE SUITABLE FOR CUTTING.
This is a vase of Achillea Perry's White.

Digitized by Google

maxima, K. caulescens and the newer varieties Lord Roberts, St. Elmo and Mount Etna, of a glowing orange scarlet (recently introduced by Messrs. Artindale). Royal Standard, Rufus and Triumph—the last is of an uncommon bronzy yellow shade—do not exceed 3½ft. in height; while the golden yellow Goldelse is barely 2ft., and the whole group of K. gracilis hybrids, the colours of which range from canary to orange, is dwarf. Groups of well grown

Eremuri

at the back of a wide border are most imposing, but, unfortunately, they are not hardy except in warm districts, and even then must have a sheltered but sunny position, while their roots (which must not be planted deeply) require protection from frost with coconut fibre or ashes. The eremuri that do best in this country are E. Bungei, with a spike of bright yellow flowers; E. himalaicus, white; and E. robustus, pinkish lilac. The most suitable

Lupins

for the herbaceous border are the hybrids between L. arboreus and L. polyphyllus. These are of many colours—pink, rose, wine red, purple, lavender and yellow, as well as the blue of the original L. polyphyllus, which has never been surpassed. Some of these hybrids display charming combinations of colour; Lady Constance, for instance, is shaded from soft lavender blue to cream; Queen of Sheba from violet to gold; Rosy Gem from rosy mauve to amber; while in Eastern Queen, mauve, pink, buff, yellow and fawn are wonderfully blended. Sunshine is a good all-yellow, but white lupins are not very numerous; Kelway's Alabaster and Enchantress are among the best. Four other good varieties are Downer's Delight, Light of Lodden, Crossroads and Glowworm. Slugs are the great enemies of lupins; the clumps should be covered with sharp cinders before they begin to shoot, and when they have made some growth these should be removed and the soil watered with a solution of alum. In all but very narrow borders

Peonies

should certainly find a place. There is such an infinite number of beautiful Chinese peonies, both single and double, that it is hard to pick out any for special recommendation; but of those sufficiently low-priced to suit the garden-lover whose means are small, the dozen named below—all Langport introductions—are among the best: *Single*, June-flowering.—Brightness and Diana, both delicate pink; Lady Wolseley, deep rose; Ida Chamberlain, pale rose; Ruby Light, crimson; Lady M. Dashwood, white. *Double* (the majority are sweetly scented).—Lady Algernon Lennox, pink shaded cream; James Kelway, white; President Poincaré, crimson; Empress Eugénie, bright rose; Limosel, lilac rose; Anna Pavlova, rose pink. The double Chinese peonies bloom in June and July, and may be combined happily with delphiniums, pale pink peonies and sky blue delphiniums harmonising delightfully. The varieties of P. arietina are good border

THE TALL AND STATELY EREMURUS.

plants; they are in pretty tones of pink and rose, and bloom in May, before the single Chinese section.

Michaelmas Daisies

are seen at their best when grown by themselves, but they are useful in the mixed border by reason of their late flowering. One of the best recent introductions is Barr's Pink, of the Novæ Angliæ class. The flowers are large, of a beautiful shade of pink, and it is a rapid grower, for a root planted in my garden very late in the autumn of 1925 had become a sizeable bush by the following September and bloomed profusely. Other desirable asters are Little Boy Blue, which comes as near to being true blue as any Michaelmas daisy ever does, is semi-double, and only 2½ft. in height; Namur, pink; Mons, deep pink; Rachel Ballard, a pretty pinkish mauve; Queen of Colwall, pale mauve; Beauty of Colwall, deep lavender blue and very double; Climax, still the best of all for cutting; and King of the Belgians; the two last being bright lavender and 5ft. tall. A new introduction of Mr. Ernest Ballard's is Pioneer, the result of a cordifolius and Novi Belgii cross; it is bushy in habit, 2½ft. in height, and its flowers are pink and of fair size. Really first-class large-flowered white asters are not numerous. Perry's White and Maid of Colwall are, perhaps, the most satisfactory; but Snowdrift and White Button are nice semi-doubles and bloom very freely; the last-mentioned has innumerable tiny white blossoms. The finest aster of the Amellus section is undoubtedly King George, with its huge violet-purple flowers; but Beauty of Ronsdorff, mauve, is nearly as good; and although Perry's Favourite has smaller blossoms, they are of a charming shade of pink. Among the more recent novelties in perennial asters, I would call attention to two: one known as Queen Mary, raised by Mr. W. Wells; and the other Ruby Tips, shown for the first time at Holland Park Show last year; both these are worth a place in the border this spring. The two first, grown in conjunction with the orange yellow Rudbeckia speciosa, will provide a truly gorgeous September display in the front of the border.

Other plants of the daisy family which deserve a place in the border are Boltonia asteroides (pinky white) and B. decurrens (white), the sprays of the latter being particularly pretty in a vase; Heliopsis B. Ladhams and the newer Excelsior, both orange yellow; Rudbeckia laciniata, single and double (too coarse-growing for the narrow border); the indispensable Shasta daisy, of which Mayfield Giant and Snowflake are rather better than the older King Edward and Mrs. Lothian Bell; Erigeron Amos Perry (lilac), E. Elsie (pink) and Merstham Glory (violet blue), all three being dwarfer and of neater growth than the old type E. speciosus; Gaillardias Mrs. J. Mackellar and The King; gold-flowered perennials such as heleniums and helianthus, of which Heleniums autumnale Riverton Gem and autumnale pumilum magnificum are two free-flowering varieties; while Helianthus rigidus Miss Mellish and H. sparsifolius are first-class tall-growing sunflowers for the back of the border; also Solidago Golden Wings with its feathery arching sprays of bright yellow flowers; and, finally—for lack of space rather than of material must bring this list to an end—there are the achilleas, A. Ptarmica Perry's White and A. millifolium Cerise Queen, both of which will flower nearly all summer.

ROSES FOR SCOTTISH GARDENS

PRACTICAL SPRING WORK

IN northern latitudes where winds are high and temperatures are low in normal winters, safety first should be the motto of gardeners. It is quite true that roses may be planted at any time between November and March, provided soil and weather conditions are favourable, but if risks are to be minimised, the earlier period should be chosen, failing which the work is better to be postponed until spring. Frequently, however, circumstances do not permit of autumn planting and in that case the amateur must not overlook the advantages that are to be obtained by early preparation of the soil for the reception of the plants in March. Ground that is of a heavy or clayey nature should be trenched to a depth of 2ft. or 3ft. so as to provide a drainage system that will prevent the accumulation of stagnant water at the roots, while the breaking up of the solid earth and the introduction of strawy stable manure, bone meal, or other materials improve the tilth and contribute to the healthy development of the plant. Should the original soil be sticky, it would be advantageous to substitute good loam, if it is obtainable in the locality.

To give the roses a good start in sandy soil, turfy loam mixed with a liberal supply of farmyard manure should be provided to a depth of 2ft. Satisfactory results are also obtained by incorporating cow and pig manure with light soil, supplemented by old turf well chopped up at the time of planting.

Two people should always be employed in the work of planting and the chief points to be observed are: (1) Dig the hole large enough to enable the roots to be well spread out; (2) See that the depth provides for the union of the graft and the stock being covered by the soil; and (3) tread the soil firmly. The distance between each plant depends on the vigour of growth, but it will be found that 18ins. is sufficient for dwarf hybrid teas. Roses planted in spring may be pruned at the time they are put in, whereas those varieties that are planted in autumn should be pruned in April. Earlier pruning is not advisable in Scottish gardens. The middle of the month is the best time, but the operation may be delayed for a week or two without proving detrimental to future success. As regards established roses, I make a practice of forking in the best old farmyard manure that can be obtained just after the plants have been pruned, as the roots are then able to make use of the nourishment at the season when they are most in need of it. New roses that were planted in prepared soil, which received a dressing of bone meal at the time of planting, require no additional food until the summer, when occasional applications of liquid manure are beneficial to the production of foliage and bloom.

There are so many good roses in commerce that the selection of varieties is largely influenced by personal taste, fragrance, soil, locality and other considerations. One must therefore be guided in some measure by personal experience and if popularity be taken as a guide, there is less difficulty in selecting a representative collection suitable for garden cultivation in Scotland.

As a class, hybrid perpetuals are no longer fashionable. With the exception of a few favourites, such as Hugh Dickson and Frau Karl Druschki, they no longer meet the requirements of the present day rosarian. Interest, however, has been stimulated by the introduction of a new crimson named Henry Nevard, which possesses the old hybrid perpetual fragrance in a superlative degree and reports from different parts of the country testify to its many fine qualities.

Hybrid teas may be divided into two groups, *viz.*, the newer roses that have already established a good reputation and those recognised as standard varieties. In the former category Betty Uprichard takes first place. Next in the order of popularity are Shot Silk and Angele Pernet, a distinctive trio of meretorious novelties. Los Angeles has also caught the public fancy, while the yellow trio composed of Mabel Morse, Betty Hulton and Florence Izzard tends to increase the perplexities of the amateur. The yellow problem is particularly interesting. For a number of years public opinion favoured Golden Emblem as the best yellow rose, but it lacked the free flowering character of Mrs. Wemyss Quin and as losses were numerous owing to an unfortunate habit of dying back in winter, its place is being filled by Mabel Morse and other new representatives.

Among the reliable bedding roses that serve the two-fold purposes of garden decoration and cutting, a selection may be made from Admiration, Mrs. Henry Bowles, Ophelia and its sport Mme. Butterfly, Lady Pirrie, Etoile de Hollande, Mme. Melanie Soupert, Caroline Testout, General McArthur, Emma Wright, Gorgeous, Independence Day, Hawlmark Crimson, Mme. Abel Chatenay, Covent Garden (beautiful in autumn), Diadem and Gorgeous.

Some people may consider that no collection is complete without Mme. E. Herriot, but the colour bleaches readily and besides hanging its head badly, growth is none too vigorous. Sunstar is another lovely flower of that ephemeral type.

Despite its spreading habit of growth, Countess Clanwilliam deserves a trial and Benedicte Sequin is another of my successes. As for single roses, there is nothing to beat Isobel and Vesuvius, while Grüss an Teplitz and Tausendschön possess all the qualifications necessary for covering a wall rapidly. Emily Gray has no equal as a yellow rambler and if there is an odd corner or exposed place in the garden where nothing else will grow, plant a bush of Conrad Meyer. Then there is a little gem of the rose world known as Rosa Moyesii, which has achieved wide popularity for its delightful colour in early summer and the peculiar elongated scarlet fruits in winter.

ST. MUNGO.

A SELECTION of FANCY PANSIES

DURING the last few years these flowers have been very much improved, and an up-to-date collection should include a good proportion of varieties of recent introduction. There are, however, a few old favourites that are still indispensable, and the following selection should satisfy the most fastidious grower.

Alexander Millar.—This is one of Mr. Frater's new varieties and was introduced last year. It is a brilliantly coloured flower and is very reliable. The blotches are plum purple, and the top petals are pencilled with plum purple on light wine colour.

Adam A. White.—One of Mr. Douglas' new varieties, and a general favourite among the 1926 novelties. The blotches are a dense brown-purple with rich canary yellow margins. The top petals are canary, suffused with light and dark purple, and with an outer edge of white. The general colour blend is very beautiful. This variety is a seedling from the well known variety, John Greig.

A. R. Stevenson.—A distinct new break, and raised by the well known Scottish raiser, whose name it bears. It has large claret blotches with margins of pale chrome yellow and wine colour. The top petals are deep chrome yellow shading to wine colour. A very beautiful flower of good quality.

Alexander Lister.—An old favourite. It has plum blotches, laced with greyish white and suffused with rose. The top petals are rose and white. This variety has probably won more first prizes for the best bloom in the show than any other kind.

Alexander Cochrane.—Another old favourite. Blackish blotches, edged with purple and white.

Agnes Cochrane.—Dark velvety plum blotches with beautiful margins of lemon yellow. The top petals are very light purple pencilled with dark purple, and banded with lemon yellow. A flower of fine texture with a good under petal.

Ada McCowan.—Dark plum blotches with margins of rose and lemon yellow. The top petals are lemon yellow, mauve and rosy purple, pencilled with plum colour and faintly edged with white. A beautiful combination.

Andrew Stewart.—A very reliable standard variety. Dark plum blotches with margins of purple and white. The top petals are plum colour and crimson.

Councillor Steel.—A favourite exhibition variety bearing large, well formed flowers of good texture. Dark purple blotches with a beautiful margin of claret and a wire edge of white. The top petals are glossy purple.

Dr. Riddell.—A very beautiful new variety of Mr. Paul's. Large dark plum blotches with claret and chamois margins. The top petals are chamois, claret and purple. This is a distinct colour break.

Duncan Gilchrist.—Another of Mr. Paul's varieties, and one of his most vigorous and reliable kinds. It has large plum blotches with margins of cream. The top petals are cream and mauve with an edging of white.

Dr. McKinnon.—A large-flowered and vigorous variety; also one of Mr. Paul's. It has large plum blotches with margins of lemon. The top petals are lemon splashed with rosy purple and edged and suffused with light purple.

Dryden McColl.—This is a beautifully coloured flower with dense blotches margined with purple and gold. The top petals are gold and purple.

David Stevenson.—A very attractive flower with dense velvety blotches and beautiful wine-coloured margins. The top petals are wine colour, pencilled with dark velvety purple and a picotee edge of white.

David Brown.—One of Mr. Stevenson's most beautifully coloured flowers. The blotches are dark plum with margins of pale yellow. The top petals are yellow, shading to wine colour and edged with very pale yellow. This variety is very easy to set up.

Gladys Turnbull.—Another new variety, raised by Mr. Frater. Large dense blotches are margined with lemon. The top petals are pencilled with violet. It is a big flower of good form and splendid texture and has a fine under petal.

Jean Lister McKellar.—This is one of the finest of the standard varieties. It has large, dark purple blotches with creamy white margins. The top petals are creamy white and purple.

James Stevenson.—This is a fine all-round variety, as good for garden decoration as it is for exhibition. It is a splendid grower and the colours are lovely. It has dark brown blotches banded with yellow, carmine and white.

NORMAN LAMBERT.

SHRUBS FOR THE SMALL GARDEN

Select the right shrubs for your garden this spring and save time, expense and disappointment by following the hints given in this article and by making a choice from the list supplied.

WHENEVER weather and soil conditions will permit, planting operations may be successfully undertaken throughout early spring. It is wise to deal during February with deciduous shrubs, leaving the evergreens until the end of March or early April.

Gaps which have occurred in shrubberies and beds should be filled, and alterations decided upon during the past flowering season carried out now.

Planting.

Although not strictly essential, the positions intended for the spring planting of shrubs are best prepared in the autumn, allowing them to remain vacant during the winter months so that the manures applied will become dissolved or decomposed into available plant food. The successful cultivation of shrubs depends very largely on proper planting at the outset, and, although some plants require special treatment, certain general rules govern all planting operations.

The first consideration is the soil. Postpone all planting while the ground is frost-bound or waterlogged. Plants received from a nurseryman during frost should not be unpacked but placed in a frost-proof shed until a thaw sets in. Shrubs planted in waterlogged conditions seldom recover. The soil should always be in such a condition that it can be worked around the roots of the plants so that all crevices are filled in.

Soil.

A medium lime-free loam is suitable for most shrubs. Any ingredient particularly required can be added at the time of planting.

To render all possible aid to the shrubs at the time of planting it is advisable to consider the following points:

(1) The habit and rate of growth of each shrub so as to allow for its unhampered development for a few years.

(2) Always consider the root system of individual plants. They may be shallow or deep rooted, fibrous or woody, and plant accordingly.

(3) Never plant a shrub with dry roots, make certain that those carrying balls of soil are wet. Too many plants should not be "laid out" ready for planting at one time, as exposure to drying winds will damage their tender roots.

(4) Positions should be selected in keeping with the natural requirements of each variety of shrub. Their likes and dislikes as regards sun or shade and moist or dry conditions must always be considered.

(5) Do not plant too deeply, more shrubs owe their death to deep planting than to any other cause.

(6) "Taking out" the holes for each plant in a thorough manner is important. Allow plenty of room for root development. Where shrubberies or beds have been well prepared this operation is comparatively simple. The bottom should be made reasonably firm to prevent sinkage. The sides of the hole should be broken down with a fork or spade. If they are left hard and smooth the effect on the plant is the same as that of a pot, and instead of the roots penetrating through they double back on themselves. This applies particularly to isolated shrubs planted in lawns, which are too often dropped into a pot-like hole.

THE GUELDER ROSE (VIBURNUM PLICATUM).
Grows equally well in the open or against a wall, and is very effective when in full blossom.

(7) Each shrub as it is being handled for planting should have its roots examined and any damaged ones cleanly severed; this promotes the growth of young fibrous roots.

(8) The roots should be spread out evenly around the hole and fine soil worked well into all crevices. The addition of a little leaf-soil to each shrub is beneficial in producing early root action. The soil should be added evenly in small quantities around the hole and trodden in. It is a great mistake to throw in a large quantity and then try to firm it.

(9) Hard, compact balls of soil are best broken up slightly with a fork, otherwise the young roots cannot push through to the new soil.

Treatment after Planting.

After planting, level over the surface of the soil, being particularly careful not to collect it around the "collars" of the plants. Attention should also be given to staking those plants which need support until they have become naturally fixed to the soil by their new roots. Occasionally evergreens need watering after planting, and to ensure the water reaching the roots the soil can be arranged in saucer-like fashion around the plants. Before the hot weather sets in give these newly planted shrubs a light mulch of well-rotted stable or Wakeley's Hop manure.

Below is given a list of flowering shrubs suitable for spring planting and easy to cultivate. All are obtainable from nurseries

MAGNOLIA STELLATA, A DWARF GROWING SHRUB THAT FLOWERS IN SPRING.
It is one of the most useful and accommodating shrubs for the small garden, where it looks well either in a shrubbery border or in a bed on the lawn.

Digitized by Google

at reasonable prices and should find a place in every garden. The time of flowering and cultural details regarding each are given.

In addition to being ideal for grouping in shrubbery borders and beds, some, such as Magnolia stellata, are particularly attractive when grown as isolated specimens in the centre of a small lawn.

Berberis Darwinii.—Evergreen, 6–12ft. high. Position sheltered from cutting winds. Good loamy soil. Produces its beautiful golden flowers in drooping racemes in April and May and again attempts flowering in autumn, when it carries an abundant crop of berries.

Buddleia variabilis and varieties Veitchii and magnifica.—Sunny position, with plenty of room. Rich loamy soil. Among the finest of all autumn-flowering shrubs.

Escallonia langleyensis.—Evergreen. Bright rose-carmine flowers borne profusely in June–July. Sunny position and sandy soil. Only damaged by severest winters.

Forsythia intermedia var. spectabilis.—Deciduous. Strong growing, needing plenty of room. Very rich soil. Yellow flowers. One of the finest of all flowering shrubs.

Hamamelis mollis.—Deciduous. A splendid plant with yellow flowers borne in January. Prefers a light loamy soil with peat and leaf-soil added.

Philadelphus Virginal. — Double white. Compact habit. Moderately sunny position in loamy soil. Flowers freely in June and July.

Philadelphus purpureo-maculatus.—Single, fragrant flowers, petals white with purple blotch at base. A good subject for grouping in a small bed. Flowering at midsummer. Position as above.

Olearia Haastii.—Evergreen. A valuable shrub for planting in town and seaside gardens. Flowers freely in late summer. Prefers light loamy or peaty soil free from lime. Valuable for most positions which are not too wet.

Veronica Traversii.—Evergreen. The best of all New Zealand veronicas for general use. An ideal subject as an isolated lawn specimen. Prefers a sandy loam. Flowers freely and regularly in July.

Ceanothus Gloire de Versailles.—Valuable as a late-flowering shrub, producing its beautiful blue flowers until the autumn frosts set in. Needs a sunny position and sandy soil. Best purchased in pots, as it transplants badly. Equally good for grouping in beds or training on a wall.

Spiræas.—A selection of shrubby spiræas should include Spiræa arguta, Thunbergii and japonica var. Anthony Waterer. S. Thunbergii produces its pure white flowers in April. S. arguta flowers a little later and is generally considered the finest of the white spring-flowering spiræas. S. japonica var. Anthony Waterer has flowers of a brilliant shade of crimson borne freely in late summer up to September. Dwarf habit, only reaching to 18ins., and ideal for grouping in a bed. All three require full sunlight and a moist loam.

Cytisus.—So many cytisuses have been placed on the market in late years that a selection is difficult. To add brilliance to the garden in May Cytisus Dallimorei and its seedling form C. Dorothy Walpole need only to be known to be more largely grown. The soil in which they are grown should not be rich, but rather sandy or stony, and a position in full sunshine chosen. Purchase in pots.

Deutzias.—Deutzias are excellent shrubs for small gardens in partially shady places. For general purposes D. scabra and its varieties are best, as they usually escape damage by late spring frosts. Preference should be given to D. scabra flore roseo pleno and Pride of Rochester. The soil suitable is a good moist loam.

Hydrangea paniculata var. grandiflora is preferable to Hydrangea hortensis for general hardiness. Requires a rich loam and mulching in spring. Flowers are nearly all sterile, and borne freely in August and September. Needs plenty of room in order to give of its best.

Hypericum patulum var. Henryi.—A useful yellow-flowered low-growing shrub suitable for grouping in beds of a well drained loamy soil with abundant moisture. Flowers from July to October.

Syringas.—Of the numerous hybrids in cultivation Souvenir de Louis Späth, single-flowered, and Mme. Lemoine, double-flowered, are recommended. A well grown lilac makes an ideal lawn specimen, and should be planted in a stiff, well drained loam and mulched in the winter. Flowering in May, a shrubbery border of mixed varieties of hybrid lilacs is particularly pleasing.

Viburnum tomentosum var. plicatum may be selected from the mass of viburnums in cultivation as one of the finest known shrubs. Should be planted in a moist, deep, rich loam. Flowers profusely in June.

Magnolia stellata has proved itself to be the most useful of the genus for ordinary gardens. Flowering early, it is sometimes damaged by winds and frost. An excellent plant for grouping in a bed on a lawn. Should be given plenty of peat at the time of planting. This is best done in May. Should never be allowed to dry at the roots.

Two shrubs suitable for covering walls which may be planted now are:

Prunus triloba fl. pleno.—Flowers profusely in March and early April, when it forms one of the most beautiful features in a garden. This should always be purchased on its own roots.

Forsythia suspensa var. Sieboldii.—A splendid climbing variety useful for covering an expansive wall or training up pillars and verandas. Beautiful yellow flowers borne freely in early spring. Soil which suits it best is a good moist loam.

The above by no means exhausts the number of flowering shrubs suitable for the smaller garden, and of necessity it does not include any rhododendrons or azaleas, which are too numerous and vary so much in habit and colour that a limited selection is practically impossible to make.

DUNHEVED.

WHAT OUR READERS SAY

CISTUS LAURIFOLIUS.

SIR,—As an addition to Mr. S. Arnott's interesting note on Cistus laurifolius in THE GARDEN of January 29th, it may interest readers to know that in an East Suffolk garden, or rather in the plantations surrounding an East Suffolk garden, six miles from the sea, Cistus laurifolius, first put in as a seedling in 1910, has taken possession of the place and is now the undergrowth, just as rhododendron is in some of the woods of the Exe Valley in Somerset. There are literally thousands of self-sown seedlings of all sizes from 1in. to 8ft. A bit of hillside planted in the early days when we thought them very rare and precious (precious they still are) with 125 carefully collected and transplanted seedlings is now a solid mass, the bushes averaging 7ft. in height—a wonderful sight on a June morning when covered with the fresh daily crop of large white flowers. Bees love them for their pollen. Would that they contained an equal amount of honey! It is interesting to see how the seedlings get about; they have appeared all over the plantations, wherever they can find a sunny open spot in this very sandy soil. Another charm of this cistus is the queer aromatic scent given off by the plant in certain states of the weather. Also rabbits do not eat it; they occasionally nip off a few shoots, but only it seems from their innate habit of destructiveness, not for food. Cistus cyprius seems equally hardy here, but being a hybrid never produces fertile seed. Villosus seeds, but rabbits eat that, and purpureus was killed last winter by frost.—F. RIVIS, *Saxmundham, Suffolk.*

SPROUTING MAINCROP POTATOES.

(ITS VALUE IN RELATION TO YIELD.)

SIR,—I was very interested in "St. Mungo's" note in THE GARDEN issue of January 29th, page 76, regarding the advantages in crop gained by starting or sprouting maincrop potatoes in boxes before planting them out. I can thoroughly endorse what he says: that a much greater yield of tubers is obtained by this means. There are many large farmers in the southern parts of Scotland who cultivate potatoes extensively that have followed the practice of sprouting their maincrops in seed boxes for years. He says that within the last four years the North of Scotland College at Aberdeen have discovered that the early sprouting of Golden Wonder potato before planting gave an increase of 25 per cent. in weight in tubers at lifting-time. I should like to say that I have followed this method annually, for the last seven years with Golden Wonder, and with an increase in crop of at least 25 per cent, as they state, over that of unsprouted seeds. I had followed this practice with Golden Wonder for three years before the discovery was made at the North of Scotland College. Four years ago I planted in a field a few lines of Golden Wonder unsprouted potatoes on May 12th. On the 28th of the month I planted an equal number of lines of sprouted Golden Wonder, sixteen days later. (This was very late for planting, of course.) In a very short time the lines of sprouted tubers came through the soil, and had made from 4ins. to 6ins. of growth by the time that the unsprouted ones had done little more than broken through. At lifting-time I secured a crop from the sprouted seeds weighing 21cwt.—splendid equal-sized table potatoes with scarcely a small one among them. From the lines of unsprouted seed of exactly the same length I only scaled 15cwt., and of these only about 12cwt. were fit for table use, the remainder being small chats, only food for pigs and seeds. I believe in giving a generous supply of well decayed manure to Golden Wonder and ample space to grow. The results have always justified my experiment.—WILLIAM GRANT, *Grathes, N.B.*

POTASH FOR TOMATOES OR POTATOES.

SIR,—I most cordially agree with "Lanarkshire's" remarks introducing the article having the above headline: the addendum is mine—published in THE GARDEN issue of January 22nd. Also, I agree with him that a balanced food ration is conducive to that stable uniform growth which betokens fruitfulness.

But, with his kind permission, I would add that excessive use of phosphates, nitrogenous matter or potash, or the lack of either, will defeat its own ends. To strengthen one arm of a tripod does not ensure increased stability,

Digitized by Google

and it is obvious that if one be taken away the whole fabric will collapse.

It is very well known that phosphates have no particular tendency to promote excessive growth. Rather do they tend to the development of a good root system, and to promote fruitfulness, early maturity with good quality—great desiderata in the culture of tomatoes.

And I trust we can agree to disagree as to wood ashes forming the best source of potash. By all means, use them if they are available; but they are not particularly a potash manure.

The most that can be said of them is that they make a very mild fertiliser, containing small quantities of all the mineral elements found in plants, apt to vary greatly according to the material from which they were produced. Also, if the soil contains sufficient lime—as it ought to—they can be applied at one dressing in the potting medium without fear of loss of potash and with the additional benefit of keeping the compost open and allowing firm potting with copious watering.

Further, he recommends saltpetre or nitrate of potash—a strong nitrogenous fertiliser, to be applied during the growing season. If the plants have set a good crop of fruit, no harm may accrue; but with the addition of this to the strong potassic fertiliser already mentioned, he seems hardly consistent, as both these manures have a proclivity to growth and formation of tissue opposed to the objective in view, namely, fruitfulness and quality. "Lanarkshire" does not say if—and how much—he has provided a phosphatic manure to balance this extreme food ration.

If it would be agreeable to him, I am sure it would be a matter of general interest—and especially for the writer—if he would kindly give the series of trials through which wood ashes reached such a pinnacle of perfection to the complete elimination of such manures as phosphate of potash or sulphate of ammonia, for the purpose he had in view. —WM. MCCARRELL, *Perthshire.*

ROSE MME. ALFRED CARRIERE.

SIR,—I was just on the point of writing a few words in praise of Rose Mme. A. Carrière when your other contributor forestalled me, but left out one or two of its great charms. The delicately clean green leaves, for one thing. With me it is invaluable. Most other roses die after a few years—no rest in the winter, which is usually mild; but Mme. Alfred survives all the rest. I have three; the oldest has grown on my porch for over twelve years, flowering profusely from early summer till well on into the winter. We have a light peaty soil, not suitable for many roses.

The only thing this rose dislikes is a wind-swept situation. I know this and give the necessary shelter; but I have seen it in other Devonshire gardens looking peaky and wretched. Given a sheltered position, and no pruning, otherwise than removing dead wood, it repays you with its charming presence and delicate scent.

Have any of your readers tried this for an edging to a border? White pink Mrs. Sinkins or, better still, the old fringed white, and underneath, white and purple crocuses? They come up through the mat of silvery green foliage, which keeps them from being splashed with mud, and look charming in the spring. Before the pinks flower, the untidy crocus grass can be tucked away neatly underneath and does no harm.

Most Apennine anemones and their various relations like a heavy soil. I cannot make them happy here in this light soil. I can grow Robinsoni and very happily on a slope in the rock garden, but nowhere else. Possibly field mice eat them: but why do they overlook Robinsons, if that is the case? Hepaticas, of course, are hopeless. I like them and have tried them everywhere, for the last thirty years or so, but they will not grow for me, sad to say. I grew one clump happily once under a hawthorn—the small dead leaves seemed to please it—but never before or since.

I saw an enquiry as to Magnolia Exmouth variety not flowering. My experience is exactly the same. My plant is about 12ft. high and as broad. On a house wall it produces one flower now and then, just to show what it can do. A very old gardener told me that the only magnolia that flowered well has brownish undernеaths to its leaves and mine is an uncompromising green all over. If it never flowered I would cut it down but as it is I go on hoping from year to year, and there is nothing else to be done. More than once I have signed a death warrant for disappointing flowers and shrubs, but when I do, they flower at once and get reprieved; but it does not act in the magnolia's case.

I should be grateful if any of your readers could give me any advice about the anemones. The magnolia, I fear, is a hopeless case, and I must content myself with its splendid shiny leaves, which are most decorative.—NORA ELLOART, *South Brent, Devon.*

PETROL OR METHYLATED SPIRIT FOR DESTROYING WOOLLY APHIS.

SIR,—I am exceedingly sorry if any phrase or expression contained in my note on the above in your issue of December 8th, 1926, should be capable of being construed as a criticism of your correspondent "R. C.'s" letter on the same subject. Petrol is excellent for the purpose of destroying these pests—in summer. I have used it myself for twenty years or more and it was, I know, formerly in common use in some of the largest Continental fruit nurseries. The object of my letter was to point out that both petrol and methylated spirit are to be regarded as essentially *summertime* remedies, and that of the two the latter is to be preferred in that it does not injure the young growth. There are plenty of winter washes and sprays which are fully as effective and far less expensive. The trouble is that during the winter months these aphides, for the most part, "take cover" beyond the reach of sprays and washes and the sharp eyes of small birds. The painting of trees in winter with either petrol or methylated spirit is largely in the nature of "destroying the nest when the birds have flown"! Had "R. C." taken into account the life history of these pests he might have also avoided the error contained in the suggestion that woolly aphis upon new growths necessarily infers serious infection or the presence of a separate variety of aphis. The fact does not warrant the destruction of such trees, as he suggests. There are, therefore, two methods of attack to be advocated in consideration of the life history of the aphis. A winter spray of ½lb. caustic soda (98 per cent.). ½lb. pearl ash and 5 gallons of water will destroy all the eggs and aphides it touches; but no spray in summer will destroy the pest without destroying the foliage, which brings us back to our starting point as to the relative merits of petrol or methylated spirit applied to the colonies with a small stiff paint brush. Of these I prefer to use methylated spirit, because it does not injure the foliage.—HERBERT G. LONGFORD.

THE CHRISTMAS DAISY.

SIR,—With reference to the Note by "R. E." on page 728 of THE GARDEN, dated December 18th last, on the subject of "The Christmas Daisy" (A. grandiflorus), I should be much obliged if your correspondent could kindly state where plants of this late-flowering aster can be obtained. I cannot find it listed in any catalogue at present in my possession.—E. A. SAUNDERS, *Havant, Hants.*

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Worm Casts on the Lawn.

One of the most efficient devices for breaking up worm casts on the lawn is made in the following simple way: A moderately sized piece of wire netting is obtained, and through this are threaded three fairly heavy iron rods, one at each extremity, and one in the centre. A hook is then attached to one of the outermost rods, and a length of rope again to this hook. The use of this device is obvious. When it is dragged by the rope along the lawn, the wire netting catches and breaks all worm casts, while the iron rods keep the implement weighted down. By using this "pulveriser" a lawn may be treated in one-tenth the time taken up when using a besom, and the work is done quite as thoroughly. A suggested size for use on a small lawn is 18ins. by 36in., but, of course, this may be varied as required.—B. D. S.

Fitting a Broom Handle.

The handles of brooms, when fitted in the usual way—that is, by simply tapering the end to fit the hole in the broom and nailing it in place—often work loose. If a cut is first made with a saw in the end of the handle to be inserted, and a wedge, slightly wider at the top and the same length as the cut, is placed therein and, with slight pressure, kept in position so that the shaft may be placed in the hole, and then driven home and nailed, there will be no further trouble with loose handles.—C. C.

Protecting Primulas and other Alpines.

An effective and not unsightly way to protect early-flowering primulas and other alpines is to plant above them a companion which makes vigorous growth in the autumn and needs to be cut back in the spring. I have a bush of santolina spreading umbrella-wise over Primulas denticulata and roses, and under its protection from frost and damp they are full of healthy buds. The santolina will be cut back hard later.—A. B. W.

Extermination of Wireworm.

This pest is the most difficult to get rid of by any simple application of an insecticide. Tomato borders in the greenhouse, now being made up with fresh turf, are generally infested with it. The following method of dealing with the trouble has proved most successful. Give a heavy dressing over the surface of the borders, of a naphthalene preparation (sold for killing (?) wireworms) and fork this in about 3ins. deep, afterwards raking over and making it firm. Before nightfall, place some old sacks or boxes of soil on the border, and next morning, on lifting these articles, dozens of wireworms will be found hiding under them. They can then be picked up and destroyed. No other method has proved so successful.—F. L.

GREENHOUSE NOTES

A Greenhouse Gem.

THE achimene is one of those greenhouse gems that is both attractive and at the same time useful. There are many greenhouse plants that are just as useful for decorative purposes when staged together, but here you have a plant that is quite distinctive among other plants for its beautiful and free-flowering habit. A large number of the varieties are of hybrid origin, being originally raised from species discovered in South America; hence it is that they delight in a fairly brisk heat for the greater part of the year, at all events, while in summer, when in flower, artificial warmth is not necessary providing they are sheltered from draughts of cold air. There is no time like the present for starting the tubers. Some pans or pots should be got ready and filled to within 1½ins. from the rim with a compost of leaf-mould, loam and silver sand in equal parts passed through a sieve. Set the tubers firmly in the compost about ½in. apart and fill up with soil just to cover them. A good temperature of about 65° Fahr. by day and 60° by night should be maintained.

Great care in watering is necessary at first until the tubers have started into growth, and on no account must they be saturated with water, but kept just nicely moist on the surface; after growth commences, plenty of water may be supplied. As soon as the stems have made about 2ins. of growth the plants should be shifted into large pots. For the second shift some 8in. pots will be required. A good supply of drainage material should be got together, and a handful or so of crocks and cinders put into the pots before filling up with compost, made up as follows: 2 parts fibrous loam, 1 part leaf-mould and ½ part silver sand, the whole passed through a sieve and well mixed together.

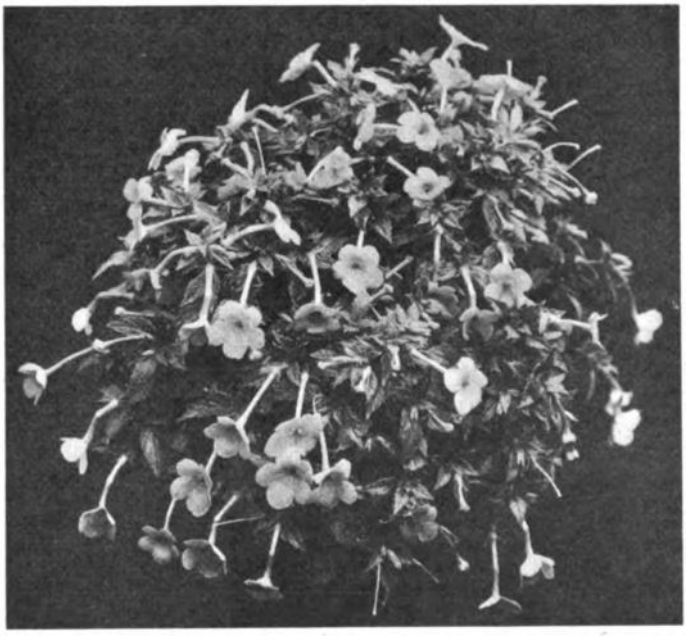
Pot moderately firmly, and after potting place the plants on a shelf near the glass in the house. In a short time the plants will commence to grow apace, but in order to prevent them becoming drawn and also to induce the plants to branch out, they should have the points pinched out once or twice, the first stopping to be done when the stems are 6ins. high.

When the flowering buds appear the temperature should be reduced several degrees to harden the plants off. An application of weak manure water given three times a week will prove beneficial by improving the flowers. These charming plants do extremely well when grown in wire baskets. The baskets should be lined with sphagnum moss on the outside and leaf-mould and moss on the inside. After planting, the baskets should be soaked with water and, when drained, suspended from the roof of the greenhouse or conservatory by means of a wire. If the plants are placed in a basket so that they grow through the bottom and sides, the effect is a most pleasing one for the adornment of the house. When the flowering period is over, the tubers should not be disturbed until the stems have died down; then carefully remove them from the pots and store away in dry sand. The best storing place is a warm greenhouse where a temperature of 50° Fahr. is maintained.

Achimenes may also be raised by sowing seed during February or March and giving the same treatment as gloxinias; but, as a rule, tubers are more reliable for coming up true.—G. B.

The Balsam.

BALSAMS are easily raised from seed and, being quick-growing, soon make an effective display. Though requiring more attention than most flowers of their class, they are, nevertheless, not beyond the skill of the average amateur. They are fine subjects in pots for greenhouse decoration, and may also be grown in a sunny window and in beds outside. A good strain of the camellia-flowered or rose-flowered will give the highest satisfaction. Seed should be sown in February or March, in a light compost of loam, leaf-soil and sand, in well drained pans or boxes, and lightly covered with a sprinkling of fine soil. A temperature of 65° Fahr. will suffice for germination. The seedlings should be kept near the glass and air admitted to them daily when outside conditions permit. When the first pair of leaves have formed, transfer to 3in. pots, burying the stems almost to the seed leaves. Water well and shade from sunshine. The next move is into 5in. or 6in. pots, and repotting should be done before the roots become in the least pot-bound, to prevent premature flowering. For the final potting a compost of 2 parts rich loam and 1 part each of leaf-soil and well decayed manure is suitable. The soil should be made fairly firm, but not pressed hard round the roots. A temperature of about 60° Fahr., with frequent syringings overhead, plenty of water at the roots, and a free circulation of air, will promote free and proportionately strong growth. Extra fine specimens may be grown in 7in. and 8in. pots, and with the aid of weak doses of liquid manure twice or thrice weekly when flower buds develop the best results are obtained. As the outside temperature increases, ordinary greenhouse conditions will suit balsams perfectly.—J. C. C.



A DWARF ACHIMENE MAKES A DECORATIVE POT PLANT.

Annuals for the Greenhouse.

THE growing of annual flowers, hardy or tender, gives but little trouble and takes a small amount of time compared with the usual greenhouse subjects. Considering the fact that seeds are cheap and plentiful and germination extremely easy without any forcing heat, every greenhouse owner with little time to spare should grow a few annual flowers under glass. An advantage is the fact that seeds can be sown at any time of the year and the plants can be had in bloom just when they are required to fill up a gap in the floral display. This gap is very obvious from May to July, when spring-flowering subjects have finished their work.

This is a good time for annuals in the glasshouse, for as the summer advances the plants give just as good a display out of doors and space in the greenhouse is thus wasted. Annuals can be sown outdoors in the autumn and the plants lifted and potted up; but they may be sown and grown on under glass early in the year. It may be advisable to germinate the seeds quickly in a warm house, and then transfer the pots to an unheated structure, placed quite close to the glass. Sow very few seeds in a pot, and thin them out when about an inch in height, leaving one or more of the strongest, according to the size of the pot. Clarkia and godetia are very ornamental treated thus, and an autumn-raised plant will grow into a specimen bush 2ft. to 3ft. high.

Some less hardy plants may be raised for summer and autumn flowering at the present time, using a little heat to germinate the seeds, and thereafter growing them in a cold house. These include schizanthuses, nicotiana, salvias, Primula malacoides, intermediate stocks, Lobelia cardinalis and syphilites.

It depends upon the conveniences and style of glasshouse available as to whether seeds of these plants are sown during January or whether the sowing is deferred until February or March; and the time during which the flowers are required is another factor governing the sowing. It should be remembered that the longer the growth under cool conditions—and even outdoors later on—the more sturdy and floriferous will the plants be. As soon as through the soil the seedlings should go quite close up to the glass, protecting them during frosty weather.

Early Vegetable Marrows.

THE great majority of the growers of vegetables do not attempt to secure a crop of marrows before the month of July. Such crops are borne by plants planted outside early in June, after all danger of frost is past. It is not possible to obtain fruits earlier by such practice, but by raising in a frame or warm greenhouse early supplies can be obtained. The small-fruited early varieties, such as Table Dainty, Improved Custard or Pen-y-Byd, should be grown. About the middle of February make up a compost of loam and leaf-soil in equal proportions, fill 3½in. pots with the soil, press two seeds 1in. deep into the soil in each pot. If available, make use of a warm greenhouse for raising the seedlings. The soil used should be moderately moist, then watering will not be necessary before the seedlings appear. Repot into 6in. pots, retain the plants on shelves in the greenhouse. In the meantime, form a mild hotbed, put on a frame and, inside, good light compost, 1ft. deep. Transplant the marrows there early in April, treat as for frame cucumbers and you will have tender fruits ready by mid-May.—HANTS.

FRUIT TREES FOR THE HOUSE WALL

Planting can still be carried out in open weather during the next few weeks.

In this article will be found a list of varieties suitable for the amateur who has only a limited space in which to grow fruit.

THERE is much to be said for the ornamental value of well grown fruit trees neatly trained to cover the house walls. There is even more to be claimed for fruit trees grown this fashion on the score of general utility, particularly when planting space in the garden is limited and the needs of shady pyramid or standard trees would most certainly clash with the interests of flower borders and vegetable beds. It is certain that there are few house walls which could not profitably

CORDON PEARS ON A HOUSE WALL.
This variety is Pitmaston Duchess.

accommodate trained fruit trees of one kind or other—even at the expense of the customary unproductive "creepers" of sorts.

There remain several planting weeks in which suitably trained trees may be established, for not until late March does the tree-planting season close.

The wall space available will largely determine the form of tree and the aspect the kind of fruit that it will be best to plant, though within certain limits the choice becomes a matter of personal taste. For while one or two kinds of fruit are eminently suited to certain aspects only, there are others, such as apples, pears, plums, etc., which will do well in almost any position. On the sunny south side of the house any kind of fruit may be grown, from the tender peach or nectarine, apricot or fig tree to the more plebeian apples and pears, currants and gooseberries. Similarly on the house wall facing west almost every kind of fruit will thrive, pears or plums often proving the wisest selection. On the east wall choice is properly limited to apples, pears, plums and cherries, and gooseberries and currants—if such a variety can be considered any limitation. The least attractive of all is the wall facing north, yet even here we can grow early pears and plums, sweet cherries, gooseberries and currants. The most generally satisfactory selection for this bleak spot is a tree of the hardy and prolific Morello cherry, however.

Regarding the form of tree to plant, the inexpert will wisely restrict choice to the easily manipulated fan-trained tree, the espalier or cordon. In one or other of these forms it is possible to train all kinds of hardy fruit.

The usual thing is to train as fan-shaped trees the peaches, nectarines, apricots, plums, sour and sweet cherries, and figs; as espaliers, the apples and pears; and as cordons the apples, pears, sweet cherries, gooseberries and currants. Occasionally plums are grown cordon fashion also.

When planning the plantings ample space must be allotted each tree, and generally the following lateral space should be allowed: 15ft. for each fan-trained tree, 12ft. for each espalier, and from 18ins. to 2ft. for each single cordon tree, double or treble stemmed cordons being planted so that their branches are at least 18ins. from each other.

Having decided these points, due care must next be given to choosing the varieties to plant. Some sorts are infinitely superior to others for this special purpose. This list comprises a few of the most generally suitable of each kind of fruit.

Peaches.—Hale's Early, Goshawk and Bellegarde.

Nectarines.—Early Rivers, Lord Napier and Hardwicke.

Apricots.—Breda and Moorpark.

Sweet Cherries.—Early Rivers, Governor Wood, Napoleon and Schrecken Biggareau.

Sour Cherries.—Morello and Kentish Red.

Plums.—Early Transparent Gage, Denniston's Superb, Bryanston Gage, Allgrove's Superb and Coe's Golden Drop.

Pears.—Conference, Doyenne du Comice and Souvenir de Congrès.

Apples (dessert).—James Grieve, Ellison's Orange, Egremont Russet, Laxton's Superb and Cox's Orange Pippin.

Apples (Cooking).—Rev. W. Wilks, Grenadier, Edward VII and Encore.

Figs.—Brown Turkey, Brunswick and White Marseilles.

Currants.—Red varieties: Perfection and Fay's Prolific; white variety: White Marseilles.

Gooseberries.—Leveller, Lancashire Lad, Lancer and Langley Gage.

It is well worth while planting really well made trees on these house side positions. To attempt to convert indifferently trained trees of uncertain form will prove disastrous, but well grown specimens obtained from nurserymen who make a speciality of trained trees for the garden will as surely prove a sound investment, providing always they receive reasonable care.

Three, four or even five year old trees are usually best for planting, there being a distinct advantage in having their branches nicely trained by skilled nursery hands.

Regarding the training of the trees to the walls, the old-time plan of securing the branches and shoots with cloth shreds and nails is not to be recommended. Not only is the nailing and tying—necessary every year—a laborious task, but the brickwork riddled with nail holes soon becomes unsightly. A better plan is to secure the branches with raffia or twine to vertical wires stretched taught between "eyelet" pegs driven in at the top and bottom of the wall space to be covered, the wires being fixed some 10ins. apart and about 1½ins. out from the wall.

In every case preparation of the soil must precede planting. Never more necessary is this than when the ground adjoining the house side is caked hard, with the top

A YOUNG SINGLE CORDON APPLE.
Note the wall damaged by nails.

layer composed in the main of builders' refuse, rubble and the like. Such unkindly conditions are typical of the soil about newly erected houses. In such cases it is best to excavate a strip some 3ft. wide and about 2ft. deep, where the tree is to go in, replacing the old soil with a suitably prepared compost. If the ground is heavy clay or waterlogged, then a small tile drain should be laid at the bottom of the border to carry away surplus water. When filling in the excavation, first should come a 5in. or 6in. layer of brickbats, then a 3in. layer of smaller rubble, and on top of this a layer of turves grass side down. On to this the compost is placed and trodden firm.

Fresh turfy loam should form the bulk of the compost used, and if to every barrowload of this is added a 6in. pottul of bone meal, the same amount of wood ashes and lime, and a quantity of finely broken mortar rubble—all being well mixed together—then you have a rooting medium in which any kind of tree will thrive. Not always need the

Digitized by Google

planter go to this trouble, of course. When the existing soil is in "good heart" the trees may be planted with no more soil preparation than a good deep digging, bone meal, wood ashes and lime being added where it appears necessary—as it mostly is.

Avoid, at all costs, the mistake of putting fresh manure from the stable or farm into the soil. Far better apply this as a mulch after planting.

At the actual planting the roots must be spread out in a semi-circular hole, care being taken not to plant too deeply. Three or four inches of soil over the top layer of roots is ample. But firm planting is essential.

Leave a space of 2ins., 4ins. or 6ins.—according to the size of the tree—between the house wall and the tree stem, sloping the tree slightly so that the branches lean gently towards the wall.

Remember that the foot of a wall is rather a dry spot as a rule, and should a dry spring follow planting the roots should be well watered and a mulch of dung spread over the surface soil.

With careful pruning—root and branch—and good cultivation in after years, including the proper control of the abounding pests and diseases, the trees should quickly arrive at fruiting age.—A. R.

THE KITCHEN GARDEN

Raspberries.

THE spell of wet weather in the autumn, in some districts, would, no doubt, prevent many cultivators getting forward with the work of cleaning the soil between the rows and other necessary work in connection with the raspberry plantation. All arrears should be made up at once. The raspberry produces roots resembling a door mat where the plant is grown in a suitable rooting medium and great care must be taken to avoid injuring any of the roots near the surface when the weeds and other foreign matter are being cleared away. Where raspberries are grown in rows there are gaps to be filled occasionally with new canes. If this is necessary now, take out all old, dead roots and those of coarse weeds, if any are found, before planting the new canes. Spread out the roots of the young plants and sprinkle some almost dust-dry soil on them before filling up with the ordinary loam. New plantations should be made and treated in a similar way. Directly any young canes are planted they should be made secure to stakes or wires, but in a free, loose way, as this item of treatment will ensure early rooting into the new soil. Then there will be the surface mulch to apply. This is a very important matter and I always favour a mulch of half-rotted littery manure then the plants receive food from it in due course.—HANTS.

Brussels Sprouts for November Use.

OF autumn vegetables I think Brussels sprouts are the most profitable. On a given space just one savoy may be grown: on the same space 3lb. or 4lb. of sprouts. The savoy may weigh more, but it will not serve a family with vegetables as profitably as the sprouts, as the latter are richer and firmer—more satisfying. The raising of the plants does, however, create more work. They are raised as follows: Seed should be sown in really good soil in boxes 7ins. deep. To guard against any possible trouble from fungus in the soil, sprinkle a small quantity of very dry lime on the surface of it in the box and then prick it in with a pointed stick. Sow the seeds thinly on a level watered surface; cover them ½in. deep, but do not water afterwards. When the two first rough leaves form, transplant the seedlings, preferably in a bed in a cold frame; if such is not available, then in deep boxes. The plants will need hardening prior to being planted in their permanent quarters at the end of April. It is the truest economy to devote the whole of the ground to the plants from the first and not attempt to grow other crops between them.—CHRISTCHURCH.

Non-Bleeding Beet.

THERE is always a danger in lifting and storing the ordinary, tap-rooted beetroot, because these roots are so readily bruised or injured; such injury causes the roots to bleed when boiled. Sooner or later, it was to be expected that a non-bleeding variety would be placed on the market; it is here now, or, perhaps, I should say *they* are here, because several growers list them this year. I wish to draw attention to these, although, let it be confessed I have only grown one, known as Bell's Deep Red. This variety in no degree differs from the ordinary kinds; its flesh is a deep purple, almost black, not unlike several of the popular dark blood-red kinds grown. The flavour is of high standard; indeed, on the table it cannot be distinguished from other good varieties. The flesh of the roots is firm, reedless, and with practically no grain. The chief merit, as indicated, lies in the fact that there is no loss of colour in cooking, even when the roots are lacerated or when they may be cut in two, to facilitate the boiling process; I have even cut the roots into pieces and boiled them, with little loss in the deep coloration.—CLYDESDALE.

Mint and its Uses.

OUR common garden mint has many uses besides that of making mint sauce, or ss the seasoning herb for green peas and new potatoes. A strong decoction of the leaves will cure chapped hands, and is useful for healing sprains and bruises. The juice of mint blended with honey is recommended by homæopathic healers for relieving earache. Our forefathers used it for making the teeth white, and it forms a constituent of many tooth pastes in use to-day. The ancienta used mint to scent their baths and as smelling salts for fainting people. The red-currant jelly commonly used with mutton can be very well replaced with mint jelly. This is made by simply steeping mint leaves in apple jelly or gelatine, a handful being enough to flavour half a pint, rendering it a delicate green colour. The liquid should be strained through a jelly bag to remove all the little bits of leaf before being allowed to set. Mice have a great aversion to mint and a few leaves of it will keep them at a distance. If a bunch of the herb is hung in the pantry mice will never venture inside. It is also said to keep away flies.

The Carrot Fly.

ONE of the most destructive pests of the vegetable garden is the carrot fly. The grub of the carrot fly is cylindrical in shape and of a pale yellow colour. It attacks the roots, and when fully grown it leaves the carrot and, burrowing into the earth, becomes a pupa, light brown in colour and oval. The perfect insect is shining black slightly tinged with a greenish hue. In a crop the presence of carrot fly is seen by the rusty and yellow appearance of the leaves. As soon as this is noticed pull up every affected plant and burn it at once. Then dust along the drills sand which has had paraffin mixed with it at the rate of two quarts per cwt. Press this around the roots to prevent the pest spreading to unaffected plants. If any of the flies are seen on the plants, syringe with soapy paraffin water. A good dusting of soot after a slight shower will also be useful in keeping away the flies. After thinning the carrots press the soil back firmly round the roots to prevent the flies laying their eggs through the earth. After an attack the ground should be dressed with gas lime. A preventive measure when sowing is to dress the drills with a mixture of lime and soot. It is also very important not to use the same ground for carrots in two successive seasons.

Practical Cropping in the Kitchen Garden.

WITH the dawn of another sowing season again at hand, most gardeners will by this time be in possession of the stock of new seeds or eagerly contemplating their arrival. It should invariably be the aim of all garden enthusiasts to endeavour to obtain the largest possible amount of produce from their gardens, and that of the highest quality. In order to achieve these results careful planning, manuring and cropping, coupled with continuous observation, are essential.

Too much attention cannot be given to the rotation of crops, and in this respect it cannot be too well known that plants of the same family should never immediately succeed each other. Perhaps in gardens of a very limited area this is difficult to avoid, but, even so, the above principles should be the governing factor as far as circumstances will allow.

Assuming, then, celery has been grown through the winter, the trenches left open through earthing-up should be well manured, placing a stick at the end of each trench, which will denote the future "line of action." As the celery is used, these trenches gradually get filled in and here can be sown peas or beans, which will prove worthy successors. When these are finished, the ground, if given an application of soot lightly forked in, provides a suitable spot for some of the brassicas. Part of the ground that was manured last year for potatoes can be allotted to tap-rooted subjects, such as carrots, beet and parsnips. These, by the way, should never be grown on freshly manured ground owing to their tendency to "fork." An old strawberry plot, manured and trenched, provides a very suitable place for autumn-sown cabbage, Tripoli onions or catch crops, such as early varieties of beet and carrot, lettuce of both varieties, radish, turnip and spinach, or peas of first-early variety.

The ground on which maincrop carrots, beet and parsnips were grown can be allotted to celery, onions or an early batch of Brussels sprouts, followed by potatoes the following season. A batch of autumn-sown cauliflowers that have been pricked off and wintered in a frame can be planted out between potato rows. Radish and lettuce thrive well on the tops of celery banks. Runner beans can be grown without robbing the garden of much space, and although these are usually grown up sticks, they can also be trained to cover trelliswork as a screen for some unsightly corner, while vegetable marrows will thrive well on the decayed matter accumulated at the rubbish heap, or, if required to do so, will climb over any old structure if supported with an occasional tie, and will fruit very readily.

In this way the best use is being made of all ground, and the results agreeably correspond.—W. F. F.

"RYDERS"

TEN WEEK STOCKS

ALWAYS popular in English gardens for their sweet perfume and charming colours, it is only since the war that Ten Week Stocks have been raised to their present state of perfection. There are twenty clear and decided colourings, details of which are given in RYDERS 1927 CATALOGUE of which the coloured plate here reproduced is but one of many beautiful illustrations.

Here is an example of TWO SPECIAL COLLECTIONS:

5086. A collection of 8 separate kinds, 60 seeds of each kind, for .. 1/-

5088. A collection of 12 separate kinds, for 1/6

Orders for either or both of these collections will be sent post free on receipt of remittance.

Ryders

1927 CATALOGUE

Every gardener, should possess this wonderful book of Flower and Vegetable Seeds sold in the economical 2d. packets. It is profusely illustrated in colour and black-and-white photographs, including a delightful plate entitled "Everybody's Flowers," specially painted by Miss Winifred Walker, the famous floral artist. A full-size copy of this beautiful painting is offered to Ryder customers, and the book is brimful of most interesting and informative Cultural Notes.

Send a post card with your name and address plainly written and this 104-page Catalogue will be sent free by return of post Address to :

THE GARDEN

VOL. XCI.—No. 2881. FEBRUARY 19, 1927. PRICE TWOPENCE.

THE CARE OF SHRUBS

Early Spring Work.

DURING open weather in February and March a good deal of general attention should be given to shrubs. The care and treatment they receive at this time do much to influence their condition in the next flowering season. The likes and dislikes of each individual shrub must be thoroughly understood. This does not only apply to shrubs in particular, but to all plants in general, if they are to give of their best.

In order to grow shrubs successfully the necessary requirements of each individual must be borne in mind, so that at time of planting the shrubs are given a correct site, a sunny or shady position as demanded, the necessary soil conditions, adding any material that may be lacking in its composition. This may be done by the application of fresh soil or by a dressing of some suitable artificial fertiliser. Select moisture loving plants for damp places and so on and find out whether certain plants like to grow in groups or as isolated specimens.

In addition to providing conditions as natural as possible, much may be done by judicious pruning, training, shaping and mulching, at the proper time.

A common fault is the overcrowding of shrubberies and beds. One cause appears to be that many amateurs, when planting a new bed or shrubbery border, fail to visualise the size to which their plants will grow in the course of a few years. The idea is prevalent that the greater the number of plants grown in a limited space, the better will be the display of flower. Such is a great mistake, as the only result is the production of much spindly growth with a consequent poor floral display. Where such cases occur, much can be done at this time to rectify matters.

In the renovation of a worn-out shrubbery or bed, commence by destroying useless plants. Examine the soil, and if this be poor, all the shrubs remaining should be lifted and laid on one side of the border. Where they are to be out of the ground for a few days, they should have their roots protected by piling soil or leaves around or covering with a layer of straw. Then trench the bed and work in some old decayed garden refuse or well rotted farmyard manure. If such is not available or is difficult to procure, some form of artificial fertiliser, such as Wakeley's Hop Manure may be employed. Finally, level over the border or bed and replant such of the old shrubs as are suitable and any new ones which it has been decided to add. Each plant as it is handled should be carefully looked over, as this is a most opportune time to examine the root system in relation to the stem growth. Any roots which are badly broken or damaged through lifting must be cut off evenly with a sharp knife, so as to promote the growth of young, fibrous roots, which are necessary to the health and vigour of the bush. It is best to think out the arrangement of the shrubs in their new positions before the actual planting. It will be generally found that the best plan is to place two or three plants in position and use these as a basis, arranging the others suitably around them according to their shape and size.

When satisfied with the new arrangement plant each carefully, spreading out the roots in a natural manner, and taking particular care not to plant too deeply. The addition of a little leaf soil round the roots will be found beneficial. Where such thorough treatment as the above is not necessary, overcrowded shrubberies and beds may be merely thinned out and the remainder of the plants more evenly spaced. Specimen shrubs which for no apparent reason have failed to give satisfaction for a few years, will often respond to being lifted out and the old soil carefully removed from their roots and new soil substituted.

The stem portions of the plants should also be looked over and all dead wood removed. It is of no use to the plant and only acts, during the spring months, as a centre for insect and fungoid disease. A few, and it may be emphasised, only a few, shrubs require a regular pruning, and in the case of the majority of our flowering shrubs only a shortening here and there of the more straggly and unruly branches is required. The early spring-flowering shrubs can all be attended to when the flowers are over, from the end of February until the end of March.

All surface rooting shrubs, such as many of the rhododendrons, will benefit by a surface dressing of some protective material, such as littery manure spread loosely around the base of the plants away from the stem. In times of late frosts it acts as a protection to the roots when they are active and easily injured. The material can be renewed from time to time and left during the summer, when it acts then, not as a protection against frost, but as a moisture-conserving factor.

It cannot be too strongly recommended that an endeavour should be made to understand the likes and dislikes of the individual constituents of the shrubbery. All shrubs do not thrive in similar soils; some like shade, others prefer an open sunny situation, and it is at this time that consideration should be given to these points, judging by past experience and alterations made accordingly. Care and attention to one's shrubs will be well repaid.

This Week's Work

Sow another batch of half-hardy annuals in the greenhouse.

Fork over any vacant ground in the kitchen garden.

Protect wall fruit from birds and frost by covering with fish netting.

Make a sowing of sweet peas in a frame.

Thin boxes and pans of seedlings as soon as the young plants are large enough to handle.

Transplant autumn-sown onions if the ground is in a fairly dry condition.

Set up in boxes second-early potatoes and place in a light shed for sprouting.

Fill in any gaps in your herbaceous border

British Columbia Horticulturists Growing Bulbs.

BRITISH COLUMBIA horticulturists are entering the bulb industry on a very large scale and a market is being found for the Canadian grown bulbs in Canada and the United States. So far, the bulb production in British Columbia has been only on a moderate scale, but a big future is seen for this industry, since Canada imported last year over 3,000,000 bulbs.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 12, which appeared in our issue of February 5th, have been awarded to

Mrs. Dodson,
6, North Road,
Surbiton, Surrey.

and

Mr. R. C. Rollinson,
Pencrebar,
Severns Avenue,
Acomb, Yorks.

To each of whom a cheque for that amount has been sent.

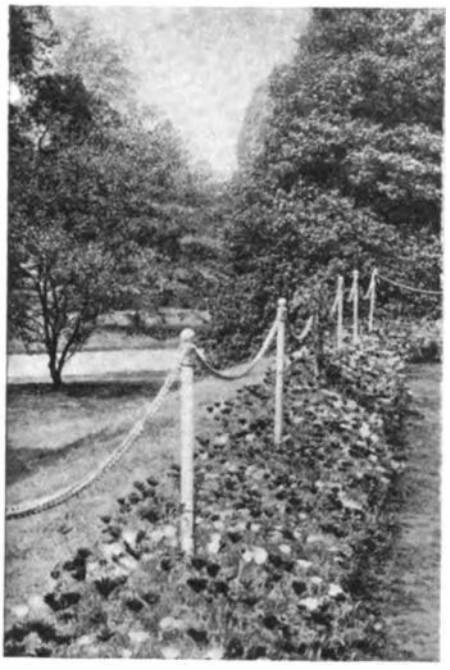
HARDY ANNUALS FOR EDGING AND CARPETING

THE difficulty of selecting attractive plants for furnishing colour and finish to path and border edgings and for groundwork to beds and borders is a very real one to many amateurs. Many annuals, by reason of their short life, their wealth and beauty of flower, their colour and habit, are particularly suitable for this purpose. A selection of choice kinds should be made from the accompanying list.



ESCHSCHOLTZIAS. THE TALL-GROWING AS WELL AS THE DWARF SORTS ARE MOST USEFUL ANNUALS FOR CARPETING.

AN EDGING OF LIMNANTHES DOUGLASII AND SHIRLEY POPPIES WHICH CHARMS BY ITS SIMPLICITY.

OF these, one of the hardiest, the easiest to grow and the most generally useful, is the well known Alyssum maritimum; but to get the best results it is necessary to obtain a really good compact strain, such as Little Dorrit, to sow in boxes early in March, to prick out on the appearance of the second pair of leaves and to transfer plants to their flowering quarters in May when they should be sturdy little plants about 2½ins. high—a plan which might be followed with advantage in the case of many other small annuals. There is a pinky-lilac variety of Little Dorrit which is pretty in a quiet way. A. maritimum procumbens Snow Carpet is very dwarf, of spreading habit and is admirable for small beds, as is white Candytuft Little Prince, the spiral variety, which is 1ft. high, being better suited to wide borders and large beds. The old so-called crimson candytuft was poor in colour, but the newer varieties, Rose Cardinal and Rose Beauty, leave little to be desired. Less well known than either of the two plants already mentioned is Omphalodes linifolia, which is 9ins. high, has starry white flowers and grey green foliage; it makes a charming edging, but is scarcely compact enough for carpeting. It is, by the way, one of the very few annuals that does not object to a moist situation and semi-shade. Asperula azurea setosa, the blue woodruff, which has pale blue flowers, will continue to bloom throughout the whole summer, but, like omphalodes, it is a better "edger" than "carpeter." Of a purer, brighter blue is Nemophila insignis grandiflora, and richer than that of either is the colour of Phacelia campanularia, which is 9ins. high. It is an early flowerer, but is a little capricious in some gardens and in its seedling stage is far too much beloved of slugs. An admirable carpeting plant is the Swan River daisy (Brachycome iberidifolia), which is now to be had in separate colours, although it is exceedingly effective sown in mixture. Little Blue Star and Summer Beauty (mauve) are among the prettiest of the distinct varieties. The daisy, the height of which is about 8ins., is classed as half hardy by some seedsmen and as hardy by others; on the whole it is safest to treat it as the former, but it may be sown in the open in May without risk.

For a very dry and hot situation the portulaca—another plant on the borderline between hardy and half-hardy—is the best possible choice. It is from 4ins. to 6ins. high and the seed is supplied in mixed colours, all very brilliant. It may be sown out of doors at the end of April. Viscaria Tom Thumb Rosy Gem is another sun-lover, but has the merit of being perfectly hardy, is a neat grower and of a pretty shade of pink.

The value as edging plants of Virginia stock and Tom Thumb nasturtiums is already fully appreciated. Indeed, the stock is more popular than it really deserves to be, for it is an uninteresting thing and apt to flop about feebly unless drastically thinned out. Of the nasturtiums the old favourites, King of Tom Thumbs and Empress of India, both scarlet, and the spotted yellow Ladybird, are still to be counted among the best, but the newer Sunset is a striking shade of pinkish orange.

Much less commonly met with than these familiar friends, are the miniature eschscholtzia (cæspitosa), much less showy than its taller kindred, but bearing pretty pale gold flowers in profusion. The rose pink Saponaria calibrica also a persistent bloomer; Eucharidium Brewerii, also pink; Sanvitalia procumbens, bright yellow; Eutoca viscida, bright blue; and Arctotis calendulacea, which has rich orange daisy-like blossoms. The two last mentioned are slightly trailing in habit, but are quite neat enough for edging or carpeting. The arctotis should be treated as half-hardy. Limnanthes Douglasii is another exceedingly pretty dwarf annual, with myriads of yellow and white flowers, which are most attractive to bees. It is exceedingly hardy, does not dislike a little shade and seeds itself abundantly, but it has the drawback of being too early-flowering to combine satisfactorily with summer bedding plants as its beauty is over by the beginning of July. R. E. HEAD.

SOME HARDY ANNUALS FOR EDGING AND CARPETING.

Name.	*Colour.*	*Height.*
Alyssum maritimum Little Dorrit	White	6ins
,, ,, Lilac Queen	Pale mauve	,,
,, procumbens Snow Carpet	White	3ins.
Arctotis calendulacea	Orange	10ins.
Asperula azurea setosa	Pale blue	10-12 ins.
Brachycome iberidifolia (type)	Various colours	1ft.
,, ,, Little Blue Star	Bright blue	6ins.
,, ,, Purple King	Deep purple	,,
,, ,, Summer Beauty	Mauve	8ins.
Candytuft	White, lilac, rose	1ft.
,, Little Prince	White	6ins.
Eschscholtzia cæspitosa (tall and dwarf)	Pale yellow	4-6ins.
Eucharidium Breweri	Rose pink	6ins.
Eutoca viscida	Bright blue	1ft.
Limnanthes Douglasii	Yellow and white	6ins.
Nasturtium Tom Thumb	Various colours	8-10ins.
Nemophila insignis grandiflora	Sky blue	8-9ins.
Omphalodes linifolia	White	9ins.
Phacelia campanularia	Deep blue	,,
Portulaca grandiflora	Various colours	4-6ins.
Sanvitalia procumbens	Yellow	4ins.
Saponaria calibrica	Pink	6ins.
Viscaria Tom Thumb Rosy Gem	Pink	,,

BULBS FOR THE COLD GREENHOUSE

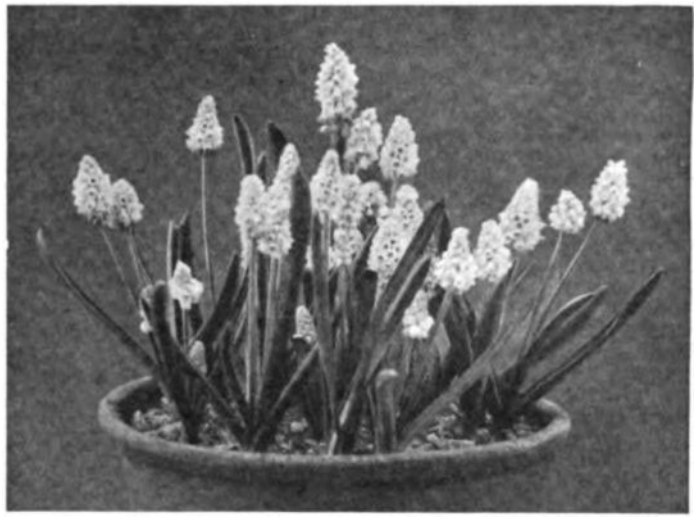
MANY bulbous and tuberous-rooted plants are of great value in providing a display of flowers for the cold house in the early months of the year. A number of them are easy to grow in pots or pans and the choice of subjects for this purpose is very extensive. Beginning with crocuses and snowdrops in January, one may have a succession of bloom for several months, provided by cyclamen, narcissus, scillas, erythroniums and tulips, to mention only a few out of a host of suitable plants. To obtain the best results bulbs should be potted up early in September in order to allow plenty of roots to be formed before winter sets in. A good sandy loam is suitable for most things, an exception being the dog's tooth violets (erythronium), which require a mixture that is richer in humus. After potting the bulbs, plunge the pans to the rim in ashes in a sheltered border and leave them there till they show signs of pushing up their flowers. They may then be brought into the house and protected from the weather while in bloom. After flowering, replunge the pans outside and keep well supplied with water till the bulbs have matured their foliage, then withhold the supply and allow the bulbs to become well ripened off. Among the more important families are:

Anemone (*Windflower*).—This genus includes the early-flowering A. blanda from Greece and Asia Minor, with its lovely dark blue flowers in February. There are also rose coloured forms, and another with white flowers shaded blue on the under side of the petals (A. blanda var. scythinica). A beautiful early spring flower is A. fulgens, with rich dazzling scarlet blooms and light, elegant foliage. Well flowered pans of this make a beautiful show and last a long time in good condition.

Crocuses of various kinds may be had in flower from August to March, the best for spring use being, among others, C. Imperati, with fawn petals, more or less feathered on the outside with violet. C. Sieberi is a charming species from Greece, with soft lavender blue flowers and golden yellow base, while the white and black C. biflorus and the pale purple C. versicolor, with distinctive feathering, are also desirable kinds. For those how desire to specialise in this genus, there are numerous other kinds.

One of the loveliest and most welcome of our spring flowers is the *Glory of the Snow* (*Chionodoxa*). C. Luciliæ has brilliant blue flowers with a snowy white centre, while C. sardensis has gentian blue flowers, somewhat smaller in size. They are produced several together on one stem, some three or four inches high.

Bulbocodium vernum, some 2ins. or 3ins. high, produces early in spring numerous bright rose purple flowers.



THE GRAPE HYACINTH, OR MUSCARI, MAKES A DECORATIVE LITTLE POT PLANT.

Cyclamen.—These charming plants are suitable for pans and usually open their flowers in January, but remain attractive for several weeks. There is C. ibericum, with its rosy purple flowers and faintly zoned leaves, and C. Coum, which differs from it in having unspotted dark green leaves. There is also a white-flowered variety of the latter, a very desirable plant. After flowering they should be placed outside to complete their growth and the corms should then be well ripened off by withholding water and giving exposure to sun.

The Winter Aconite (*Eranthis*), produces its golden blossoms early in spring, each flower resting on an emerald green cushion of leaves. In addition to our well known native species, E. hyemalis, there is one from Asia Minor, E. cilicicus, with larger flowers and a more finely cut frill of leaves.

A valuable family is the *Dog's Tooth Violets* (*Erythronium*), several of which can be grown in pans in a shady frame. E. californicum is a beautiful species, with handsomely mottled leaves and stems 9ins. high, bearing several large chrome yellow flowers with orange markings. A. Hendersoni has pale lilac flowers with a purple centre, and is one of the most distinct. A. revolutum varies in colour from bright rose (var. Johnsoni), to a form with large creamy white flowers having a golden central ring, and brown mottled foliage (var. Watsoni).

The Snowdrops (*Galanthus*) are too well known to need description. The best of all for our purpose is Elwes's Snowdrop (G. Elwesii, from Asia Minor, with broad glaucous leaves and large flowers which appear in January. G. cilicicus, a smaller kind, flowers still earlier, sometimes in full flower in December. G. latifolius has broad, arching, deep green leaves, and with G. plicatus comes into flower in February.

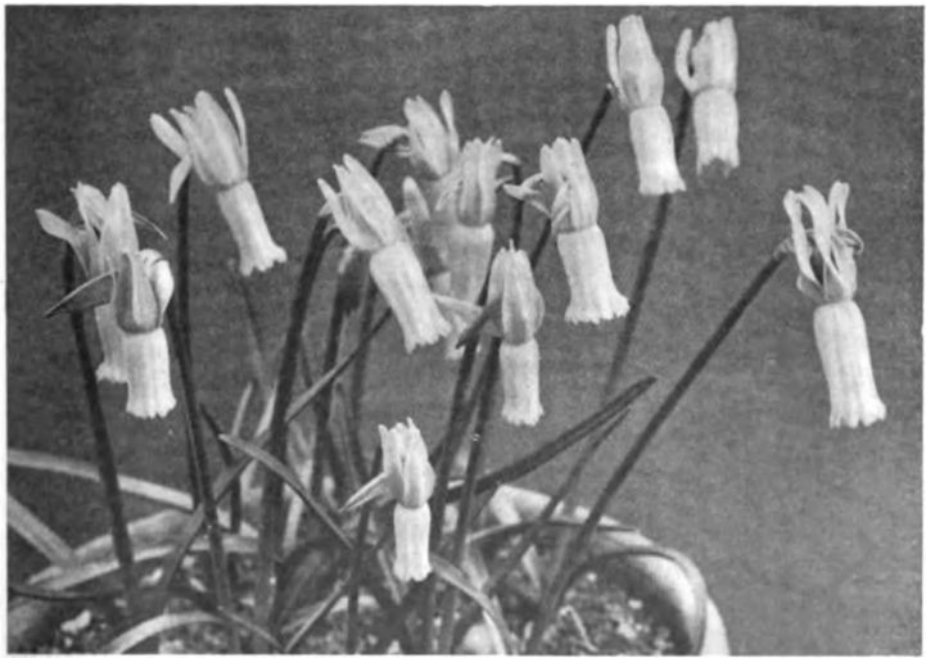
A beautiful little plant is *Hyacinthus azureus*, with little spikes of Cambridge blue coloured bells in February. It is also known as Muscari azureum. Some of the muscaris, or grape hyacinths, make lovely pot plants, one of the best being "Heavenly Blue," with tall spikes, well furnished with bells of the richest shade of gentian blue. M. neglectum has large blue-black flowers.

Many of the dwarf *Irises* are indispensable, such as the golden netted iris, I. reticulata, with its violet-scented flowers in February, while an earlier flowering kind is I. histrioides, with bright blue flowers, having a golden yellow blotch. These are only two out of a large number suitable for growing in the cold house.

The *Narcissi* form another valuable family of bulbous plants, some of the smaller-growing kinds being well adapted for growing in pans. The earliest flowering kind is the snowy white hoop-petticoat daffodil from Algiers, N. Bulbocodium var. monophylla. Others are Angel's Tears (N. triandrus), and the cyclamen-flowered daffodil (N. cyclamineus). The smallest of the family is N. minimus, only 2ins. or 3ins. high, with a miniature frilled trumpet.

All the bulbs above mentioned are easy to grow in any good sandy loam with some leaf soil and sand.

W. I.



NARCISSUS CYCLAMINEUS IS A MINIATURE DAFFODIL WELL ADAPTED FOR PAN CULTURE IN A COLD HOUSE.

A BED OF EVERLASTING FLOWERS

IT is not often that one notices much attention being given to growing a representative collection of flowering plants in the garden, the characteristics of which are commonly understood when referred to as "everlastings." Nevertheless, there are subjects among hardy perennials, hardy and half-hardy annuals and biennials that serve our purpose, and, without much difficulty in regard to culture, can be taken in hand by most people who own a garden.

Spring is a suitable time both to review and to make arrangements for planting and sowing most of them, and though it is not suggested that flowers carried by them are equal to fresh cut, it has to be borne in mind that by far the greatest number of gardeners have no greenhouse from which to gather supplies when outdoor blossoms have gone. We submit that "everlasting" flowers fill a place in the home during winter and early spring and relieve the bareness at least of vases that otherwise would be empty. Taking hardy flowering plants which may be planted its double forms are not the least serviceable for anyone who desires to have something in the room long after summer flowers have left us. During this last autumn and winter a vase of the double variety kept its colour well and, though some of the buds shrivelled, it gave a light, pleasing appearance to a corner of my room.

With the exception of gypsophilas, all the above hardy plants will grow in very ordinary garden soil. In the case of gypsophilas, however, lime must form some part of the texture of the soil, and if the latter does not contain lime it should be made up by lime chippings or old mortar rubble being dug into the ground at the time of planting. No shallow digging will do for them, as they are deep rooters and need the soil being worked to a depth of 2ft. or 3ft.

Annuals.—Of these, the seed of the bulk of them should be sown, either in pans of light soil in the warmth of a house towards the end of February or March, in a cold frame in April, or out of doors at the end of May.

THE ATTRACTIVE PAPERY BLOSSOMS OF RHODANTHE MACULATA, ONE OF THE EVERLASTING FLOWERS.

in February or March, we have eryngiums (sea hollies), with bracts of glistening blue and white, as represented by E. alpinum (bracts metallic blue), E. amethystinum (amethyst-purple bracts and deeper coloured stems), E. giganteum (white stems and bracts). The echinops (globe thistles) also furnish heads of which two are useful for the garden, *viz.*, E. Ritro (deep blue) and E. sphærocephalus (light blue), should be included. Sea lavenders (statice), plants having broad green foliage and spreading panicles, are worthy of consideration in getting together a collection of everlasting flowering plants. Chief of the family is S. latifolia, with bluish flowers produced on low-spreading panicles often 2ft. across in established plants. Physalises (bladder cherries) are very popular from a market point of view, though comparatively few amateur gardeners appear to grow them. They are seen to their best advantage in late autumn, when the orange and red pods glow with vivid colour, and are useful both for home and harvest festival decorations. There is yet another hardy plant much in evidence to-day, gypsophila. This, too, bears its flowers in billowy panicles, sometimes a yard across, and G. paniculata and Comprising the most suitable are helichrysums, statices (annual sea lavenders) and acrocliniums. Rhodanthes (miniature daisy-like flowers) are exceeedingly pretty, but are best grown in pots, twelve to fifteen in a 6in. pot, being raised from seed sown in light loam and leaf-mould in the warmest corner of the greenhouse, the plants got into pots when an inch or so high, watered with care and kept near the glass as long as possible. A few thin twigs will be needful to keep the fragile, pea-like growths in position. There are pink and rose and silvery white sorts, and all are charming and dainty when in bloom.

The biennial which stands out prominently as necessary to a representative collection of everlasting blossoms (though, really, it is not the blossoms but the seed-pods which count) is Lunaria biennis, our old friend honesty. Seed of this should be sown in the open ground in May, plants got out into beds for the summer as soon as large enough for removal, and finally, in the autumn, being planted in their blooming quarters, which should be in a warm and well drained situation.

How to Gather the Flowers.—Blossoms intended for winter decoration should be gathered when half opened, as, unless this is done, in the process of drying they open still further, so that fully expanded flowers are liable to shed their petals and become useless.—CLAREMONT.

A SELECTION of FANCY PANSIES

IN my previous article I gave the names and colour descriptions of a number of up-to-date varieties and some of the older favourites, but the list was not exhaustive, and the following kinds would complete the selection.

James Brown.—Large, dense, dark purple blotches, with margins of cream and rose. The top petals are purple, heavily pencilled with plum and a wire edge of cream.

John Whiteford.—A bright wine coloured self with dark blotches and broad margins of wine colour. A very reliable standard variety.

John Greig.—Purple blotches with crimson and yellow margins. Another useful standard sort.

Mrs. A. B. Cochrane.—This is one of the finest fancy pansies ever raised, and it is a general favourite. It has dense purple blotches with beautiful margins of rich cream. The top petals are blotched and pencilled with purple and shade out to cream. It is a large flower of good texture, a strong grower and very free-flowering.

Mary Drummond.—Probably the best yellow on the market. One of Mr. Paul's famous seedlings. The blotches are brown and the margins yellow and crimson. The top petals are yellow edged with crimson.

Mrs. Alex. McAlpine.—Dense black blotches with broad margins of French white. The upper petals are plum purple and white.

Mrs. Thomas Hill.—Dense black blotches with broad margins of deep canary yellow, edged with wine colour. The upper petals are canary yellow, pencilled with dark purple with a band of wine colour.

Mrs. Henry Anderson.—Deep violet blotches edged with cream. The top petals are cream streaked with violet. A fine round, smooth flower. A very strong grower.

Mrs. Thomas King.—Dark blotches edged with gold and laced with crimson. The upper petals are yellow with a broad crimson band A flower of beautiful colouring.

Miss Nellie Thomson.—Large, dark velvety blotches margined with wine colour. The top petals are splashed with dark velvety purple with a large band of wine colour. A very fine dark pansy.

Mrs. Thomas Kennedy.—Large clean cut, dense brownish-black blotches with margins of canary yellow. The top petals are splashed with canary yellow and purple.

Nellie Cochrane.—Large light purple blotches with a double margin of claret and an outer edge of white and crimson. The top petals are white with a heavy band of crimson. A flower of fine colouring and good texture.

Robert Beveridge.—Deep purple blotches, margined with magenta shading out to white. The top petals are white, streaked with purple and edged with magenta. A large flower of bright colours.

Robert Allan.—Dense, dark purple circular blotches with margins of white. The top petals are rosy purple, edged with white, with pencillings of dark purple. Perhaps the largest of Mr. Paul's introductions.

Susan Milligan.—Large purple blotches with rose margins, shading out to light rose. The top petals are dark heliotrope shading out to a lighter tone with a white edge.

T. B. Cochrane.—Large dense Prussian blue blotches with margins of white. The top petals are splashed with dark purple, mottled with light purple and white. A large flower of good texture and probably the best of its class. NORMAN LAMBERT.

PRACTICAL PARAGRAPHS on POPULAR PLANTS

We give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

Thyme. THYMES have come into much greater prominence during the last few years since the special interest shown in the building and furnishing of rock gardens. We know them as creeping, aromatic plants which bring bright patches of colour in the time of their blooming. Some of them are carpeters clinging close to the ground or pieces of stone and blooming in June; others are dwarf shrubby little plants about 4ins. in height. Thymes will grow in any ordinary garden soil so long as the position is sunny and, once established, grow rapidly. They can be propagated either by division in spring or autumn, or from cuttings inserted in sandy soil after the plants have bloomed. For a dry situation thymes should not be overlooked.

THYME, WITH ITS SPREADING MASSES OF LIGHT PURPLE FLOWERS, IS ATTRACTIVE IN THE ROCK GARDEN.

Alyssum (Madwort). THESE spring-flowering perennials enjoy a wide popularity, as do also the annual forms which bloom in the summer. The former has yellow and golden blossoms, and come to their beauty stage in April and May. About a foot in height, they are favourites with many for grottoes and certain positions in the rock garden, while one, A. saxatile, is much used for spring bedding. Three methods are open to the grower for propagating: by seed sown in light soil in the borders in April, by cuttings taken after the plants have flowered, and by division of roots, which may be in October or spring. Almost everyone is acquainted with the annual sweet alyssum with its white flowers, a plant much used for edging purposes. There is a lilac form, too, and a very dwarf sort, also producing white flowers, employed for carpeting and for sowing in pathways in the rock garden. Seed can be sown under glass—a cold frame suffices—in pans of light soil or where the plants are wanted to bloom. This alyssum is a noted "self sower."

ALYSSUM IS VERY FREE FLOWERING AND EASILY GROWN.

Nasturtiums. THERE is scarcely a garden, however poor the soil may be, where nasturtiums will not grow, provided they are sown where the sun can reach them; in fact, one might say, the poorer the soil the greater the output of blossom. One can use the Tom Thumb sorts for edgings to beds and borders, the tall sorts for twining on pillars and fences and training up walls, and no garden, however mean, if only the sun can reach it, need be anything but brilliant for months in the summer and autumn, by sowing seeds in succession for a few weeks commencing in April. Dryness at the roots will prevent their progress, so that plenty of water should be given the plants in weeks when no rain falls. The flowers are delightful for cutting, and the more this is done, and the plants prevented from producing seed, the longer will the display continue.

Sidalcea (Greek Mallow). INCREASED interest is being shown every year in the sildacea, one of our best hardy perennials for massing in the garden. Growing about 3ft. in height and yielding many spikes of blossoms from July for many weeks, its value for planting in groups is more appreciated by amateurs, because its culture is of the simplest. It needs but good ordinary soil and a sunny position and in a dry time, plenty of water. Planting may be done in March, when roots may be divided. It can also be raised from seed sown in pans of light soil in April.

Veronica (Speedwell). THE veronica is a large and interesting family of hardy herbaceous perennials, that will grow either in a town or country garden, bearing flowers of blue and white and rose from June to September, if care is taken to cut away old flowering stems and thus encourage lateral growths to bloom. They love the sun, but need not be left out of arrangements in planting a half-shady border and can be relied upon to do well in the garden of an amateur where the soil is only moderately good, as is sometimes the case near a town. They are effective if planted in groups or between white flowering campanulas. Propagation is by division, which may take place in late autumn or spring. They grow from about a foot to 3ft. or so in height.

Verbena (Vervain). A VERY showy flowering plant is the verbena, treated with very few exceptions to-day as an annual by sowing seed in pans of light soil in the warmth of a greenhouse in February or March, pricking off the plants when they have made 2ins. of growth and, after hardening them off in a cold frame, planting out towards the end of May or early June. They delight best in a light soil and a sunny position. A cold heavy soil is unsuitable. They are very effective in beds to themselves or occupying a stretch of a border and the growths pegged down, blooming profusely from July to September. Two varieties to which attention is called are V. chamædryoides, with scarlet flowers, of perennial habit, hardy in sheltered localities, but in others needing a covering of leaves or similar protection; and V. venosa, also of perennial growth, hardy in many places, but is best served by being lifted and placed in cold frames in winter. The flowers are of a vivid purple-violet, a very telling colour in the garden from July to often late in autumn.

VERBENA IS A SHOWY PLANT FOR BEDS AND BORDERS.

THE BUSY MAN'S PAGE

Seasonable Work for February.

IF there is any pruning of fruit trees and bushes not yet finished, it should be completed during the month. Where the soil is found to be in a good friable working condition, not sticky or pasty, the first opportunity should be taken to finish the planting of fruit trees and bushes, placing a stout stake to each tree as the work proceeds. A piece of sacking, old leather or rubber tyre should be tied round the stem of the tree at the point where it is secured to the stake to keep the cord from cutting into the bark. Fruit trees and bushes will all benefit very much in cleanliness, general health and in the eradication of insect pests and improvement in crops if sprayed with some approved insecticide and fungicide (such as Bentley's Orchard Spray) and applied before the buds burst. For the removal of moss, lichens and fungus on old trees it will be necessary to use an alkaline wash, and used only when trees are dormant. Where there is still some vacant ground to be dug, endeavour to have the arrears overtaken this month. A small sowing of an early cauliflower, cabbage, sprouts and lettuce should be made now in boxes and placed in a cold frame to germinate, pricking out the seedlings when large enough to handle. Do likewise with a pinch of parsley seed, giving them a free rooting compost when pricked into another box, plenty of sifted leaf-mould and sand and only a small part of loam. Much better results are obtained with parsley in this way when transferred to open ground than if seeds are sown outside. Where shallots find favour the bulbs should now be planted on well manured soil 8ins. to 9ins. apart and 12ins. between the lines.

A sowing of early dwarf peas and broad beans should now be made in a warm, sheltered border. Potatoes that are being sprouted in boxes should be exposed to plenty of light to make sprouts sturdy, but keep well secured from frost.

New Life in Old Climbing Roses.

WHAT garden, where roses are grown, would be complete without the old favourite climbing varieties, Gloire de Dijon, W. A. Richardson, Climbing Caroline Testout and many others, which give such pleasant effects in their season. A feature often observed on very old plants of the above types, is the strong, bare wood, which gives a bad appearance. To remedy this bareness, the following simple method will give the best possible results. In re-arranging and tying in to whatever support is available, just take and bend the old growth in every way they will yield, with as much strain on the bend as is possible—even to breaking point does not matter, so long as there is no severance. At the next growing time, there will be seen breaking from the very numerous dormant joints, latent buds, which will grow into strong lengths of healthy, vigorous shoots of the kind desired for covering with new life very much of the bareness so objectionable to look at. These new shoots will also be found extremely useful for future bloom display. I have never known this simple plan fail to answer.—A. B.

Pentstemons from Seed.

THE pentstemons are among the finest summer-flowering plants for the open garden. They are excellent subjects for beds or borders, and may also be used as cut flowers. In addition to this, they also prove very useful for filling gaps in the herbaceous border. They may be obtained in a great variety of colours, ranging from white to deepest crimson, and these named varieties must be propagated from cuttings.

There are, however, so many fine forms and colours to be obtained from seedlings that named varieties are hardly necessary. Seed should be obtained from a reliable source, and sown early in March in shallow boxes or pans filled with a light compost. After sowing place in a warm house, cover with a sheet of glass and shade with a piece of paper until germination takes place. When the seedlings appear, remove the glass and paper, and stand the boxes on a shelf near the roof-glass, only shading from very bright sun. Water with care and on sunny mornings a misting over with a fine syringe is highly beneficial.

So soon as the plants are large enough to handle, prick them off into other boxes in the same manner as antirrhinums are treated, using a compost containing a liberal proportion of leaf-mould; return to the warm house until they have become established, and then gradually harden off in a cold frame so that they will be ready to plant out at the end of May or beginning of June.

The pentstemon succeeds best in a well manured, deeply dug, moist and rather sandy loam, and it is advisable where possible to dig in a liberal quantity of leaf-mould. On dry soils watering will be required during hot spells of summer weatner, and in all cases applications of weak liquid manure are of great benefit when the plants are in full bloom.

If it is desired to perpetuate any seedling of especial merit, basal cuttings should be taken in early September and dibbled in a sandy soil in a cold frame. The frame must be covered with mats during frosty spells, but on all favourable days in winter and spring ventilation must be given. These plants will be ready for transferring to the open ground in May.

In most parts of the country pentstemons will survive the winter quite well if they are cut down to the ground after the first frost which damages their foliage, and a mulch of strawy manure is placed around the roots; but, generally speaking, young plants are preferable as these last longer and produce the finest flower spikes.—T. H.

Lime in the Garden.

AS a purifier and cleanser of garden soil there is nothing to equal the judicious use of lime. When the garden shows signs of acidity, is suffering from over-manuring, or is infested with all kinds of insect pests, then lime is wanted, and its application will soon put matters right. So, too, when the soil is heavy and clayey, lime comes to the aid of the gardener by breaking it up and lightening it.

Chalk lime can be procured from any builder's merchant. The writer has found it a good plan to purchase it unslaked. The lime already slaked is powdery and apt to fly about when being applied to the garden. In the unslaked condition chalk lime is in lumps, of the average size of a cricket ball. It is, in this condition, much more satisfactory to handle. The price is, at the present time, about half a crown a bushel, delivered.

Keep the lime away from damp until ready for use. When ready to apply it to the garden the chalky lumps should be broken up into pieces about as big as a cob nut. The breaking is easily done with a hammer or mallet.

Spread the lumps, and smaller pieces resulting from the hammering, over the garden thinly. A bushel will cover from 100 to 150 square yards to work effectively, and this quantity and area should be adhered to fairly closely. The lime should now be worked into the ground by raking to a depth of 2ins. or 3ins.

If the ground be at all moist one or two days will be found sufficient to break up the lumps into powdery masses. Further raking should then be done to work the lime in deeper, and to disperse it about the soil. Dryness will make the slaking of the lime take somewhat longer, but a few days should see it powdering and ready to be worked in.

After a few days the fork can be used with advantage and the lime thus caused to enter deeper into the soil.

Treated early in the year in the manner described, ground which has previously been acid, heavy or infested (and because of any of these disadvantages bearing few and unhealthy-looking plants), will be found to be greatly improved.

Watering Wall Trees.

IT should never be forgotten that the soil in a border close to a wall often become extremely dry, and this may happen some time before the more open parts of the garden have recovered from the heavy rains of the winter. Dryness at the roots is a common cause of fruit trees trained on walls failing to "set" their fruit or, at a later date, of the small fruits falling away. If the soil around the base of the trees appears to be dust dry, fork it lightly and then give the ground a good soaking of water. Mild weather should be chosen for this treatment, and, at this early season, it is best that the water should be given in the morning, so as to avoid unduly chilling the ground just at nightfall. Later on, when the leaves of the fruit trees are developed, there is a great danger of dryness affecting the development of the crop. The foliage of the trees screens the ground so that even the heavy rains which may come with thunderstorms hardly reach the soil at all. All wall fruit trees would be the better for occasional watering except in the depths of winter.

Pruning Clematis.

The Kinds to Prune Now.

NO time should be lost in pruning those kinds of clematis which need hard cutting each year. The types which require this treatment are Jackmannii, lanuginosa and the Viticella groups, all of which should be cut back to within three or four buds of the base of the previous year's growth. This is done owing to the fact that the plants blossom on the young shoots. On the other hand, to cut the florida, montana and patens sections now is the same thing as cutting away the flowers. Really, the less pruning these types have the better. When growth starts away after pruning it is desirable to train the young shoots carefully rather than allow them to grow in a mass. If the stems are well spread about, the effect when the plant is in flower is much enhanced.

Trapping Wireworms.

WIREWORMS are often one of the most serious pests with which the gardener has to contend, and this is especially the case on newly dug grassland. Many of the plans recommended for fighting the wireworm trouble are only partially successful, and probably the best way of protecting crops is to set traps. Bury potatoes or carrots in the ground to the depth of 3ins. or 4ins., each one having a small stake pushed into it. By this means it may be removed and examined every other day. From a number of these traps quantities of wireworms may be removed and destroyed. Further, to a large extent, the wireworms concentrate on the potatoes and carrots and leave the crop alone.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

A Beginner's Rock Garden.

ROCK gardens can be made in a great variety of forms, but wherever possible they should be made so that the slopes of the rockery get the maximum amount of sunshine. Making the rockery in an odd corner of the garden, perhaps under the drip of trees and in entire shade, limits the selection of plants severely. In full sun the rock garden gives wonderful carpets of colour, besides being a suitable site for many of the rarer gems which would certainly perish under the drip of trees.

Weathered limestone from the hills of Yorkshire is the ideal stone, but a satisfactory and very much cheaper rockery can be built from old cement blocks, bricks and stones, which can be bought in many localities for a small sum. Sandstone is good, but as this is drier than limestone, it should be used with liberal dressings of lime and leaves in the soil. Bricks are similar to sandstone.

Arrangement of Stones.

Whatever material is used, the rockery must be built to resemble a mountainside, where bare rocks protrude in places, and pockets of soil are left here and there, in which the plants obtain root-hold. Size is immaterial. Half a ton of stones and a load of good mixed soil (two parts loam, one part sand and one part leaves) would make a useful and pretty rockery. The position of the stones is of great importance. Those protruding from the soil should slant so that the rain is carried into the rockery, and not off it. In shape and general design the rockery can be an expression of your own taste, a fern-covered knoll, a steep bank (like a railway cutting), a moraine (the pell mell heap of stones at the foot of a glacier), a dry ravine with a path down the middle, or simply a low wall which supports a small border. Ordinary garden soil with a little loam added is a suitable basis. It is best to leave the addition of lime until you are actually ready for planting, so that, should you desire to grow peat-loving plants, such as heaths and rhododendrons, which dislike lime, you can use the lime only where it is desired.

The rare alpines need special care, and the beginner would be wise not to attempt their culture, particularly if his garden is in or near a town. But this does not mean that you can neglect any rock garden. Weeds must be kept down and the soil surface stirred occasionally with a hand-fork. Plant carefully. A common error is to leave the plants too far out of the ground. If your rock garden is not too large, *remake it every three or four years.* In a town garden this is particularly advisable, as the surface soil becomes soured with atmospheric impurities.

Division of Perennials.

THE best and biggest flowers cannot be grown from overcrowded root stocks. The newly formed outer portions of such roots as perennial asters always give the best bloom. It has been found by practice that the best time for division of roots in or near towns is the early spring. At any time from now until the new shoots are a few inches high the division can take place. Almost all of the fibrous rooted perennials benefit from division at least once in three years, and some of them are best divided each year. Plants such as poppies and peonies, with soft, sappy roots, should rarely be divided, as they take a long time to recover.

It is often thought that a very rich soil must be provided for perennials, but if the soil is very deeply dug when the herbaceous border is first made and a supply of fertiliser incorporated at the same time, it will retain sufficient plant food for a fairly long period. Bone meal—3 ozs. to the square yard—is excellent for use in this way.

Choose a fine day for the division of perennials, and lift only as many plants as you can comfortably divide and replant on that day. A small border, say, 6ft. by 2oft., could have all the plants lifted and replanted in an afternoon, but a larger border should be done in patches. In most cases only a small portion of a clump will be required for replanting, and the outside pieces with strong shoots should be selected. About six stems are usually sufficient in the place of one large clump. It simplifies the work of re-arrangement if you lay the plants out on the dug soil in the places where you intend to plant them. Group according to the height and the probable breadth of each plant.

Succession of Bloom.

An important item in planting a herbaceous border is to secure a succession of bloom. From early spring until late autumn there should always be something flowering. Selection of plants is, for the experienced gardener, a matter of taste, but the beginner would find the following a useful guide: Forget-me-nots, doronicums, wallflowers, Geum Mrs. Bradshaw, irises and Oriental poppies. Plants of these could be purchased now for a new garden. Gladioli, roses, lilies, montbretias, phloxes, heleniums, Michaelmas daisies, sunflowers and red hot pokers will give flowers right on to the very early days of winter. I have known the valiant red hot poker to hold its flaming torch erect all through December and early January. Certain plants like forget-me-nots and wallflowers or tulips go well together.

A CAREFULLY PLANTED TOWN GARDEN WHICH IS ATTRACTIVE FROM EARLY SPRING UNTIL LATE AUTUMN.

Jasmine—Gold and White.

THE bright green stems of golden jasmine are now plentifully covered with yellow blossoms. It is eighty years since Robert Fortune, a plant collector, brought the first winter jasmine to this country, and since then its popularity has steadily increased. The leaves are usually green, and appear after the flowers are over, but there is a golden-leaved variety. The companion to the winter jasmine is the sweet-scented white jasmine which flowers during summer, and which can be obtained with either single or double flowers. Both these shrubs are excellent for covering walls either in town or country gardens. They are easily trained, requiring little or no pruning, and if grown in association so that both summer and winter flowers are produced, they transform an ugly bare wall into an object of beauty.

A Climber for Every Garden.

NEXT to roses, clematis is the showiest of climbers, and unlike roses, most of the varieties of clematis will grow and flower even in the smokiest districts. They are a very extensive family and hybridists have produced numerous garden varieties with large and brilliantly coloured flowers. Their climbing habit enables them to be grown in the tiniest of gardens, or even where the only garden available is made in tubs or window boxes. They like a sunny wall for preference, or a situation which receives during the course of the day a few hours sunshine, although I have seen them flowered successfully on a north wall.

A newly planted clematis needs no pruning the first year, being simply tied to its support. The time and method of subsequent pruning depend on the time of flowering and mode of growth. Early flowering sorts, like montana, which has masses of lovely white flowers in spring, must not be pruned now. Whatever restriction of growth is necessary should be done immediately after the flowers are past. Late flowering sorts, like Jackmanni, the old purple clematis which does so well in London gardens, flower on young growths of the current season. These may be pruned now or as soon as the new growth commences. The reason for waiting until this time, is that it is sometimes difficult to tell what stems are still alive, and until growth begins, one may easily cut out live wood in mistake. The pruning need be very slight if the plant is wanted to cover a large area, but more severe if outgrowing its allotted space.

For covering a porch or arbour, Clematis montana is one of the best. It has tiny white flowers which bloom in great profusion on the stems of the old shoots. It is specially useful for training along verandas, where its long shoots can be allowed to hang down like a curtain. Many new varieties are listed in trade catalogues, one of the best being rubens. All may be planted during the next few weeks in open weather.

NOTES ON THE FLOWER GARDEN

The Blue Flax: Linum perenne.

BLUE seems to be a colour upon which gardeners cannot agree, but there is no doubt as to whether the flowers of Linum perenne are blue or not. It is a clear, sky blue, without a shade of red in its colouring, the blue of the harebell, or the dainty little butterfly, the "chalk-blue," so well known to those who live in chalky districts. It revels in full sunshine, the flowers closing up in dull weather, and is seen at its best in the early part of the day, the blooms opening long before the gardener is up and about.

It continues flowering and casting its petals all through the latter part of May, the whole of June, and the first week in July, by which time the earlier blossoms have so set their seed that the stems bow down under the load, when the plants should be sheared down to within 6ins. of the soil. The plants thus released from the strain of seed bearing, commence almost immediately

THE BLUE FLAX USED AS AN EDGING IN FRONT OF THE HOUSE.

to push out new flowering growths, which culminate in a further display six weeks from the cutting down.

Growth commences very early in the year from established plants. The merest suggestion of warmth makes the pretty, dainty foliage push forth. When this is observed the supports should be placed in position. These may take the form of short, twiggy pea boughs, small stakes connected by means of green twist, or better still, wire netting of 1ft. width and 1in. mesh, supported 1ft. above the plants by means of stakes driven into the ground. The growths will soon push through the netting, which will be completely hidden before blooming takes place.

As a plant, L. perenne is by no means exacting. Although happiest in a border receiving full sunshine, it will thrive in almost any position except absolute shade. In the writer's garden the plant is used as an edging in borders facing south, east and west, and there is little to choose between the actual blooms in any of the three positions. The greatest mass is produced in the border which faces south, but this may be due to the fact that this border received a heavy dressing of lime rubble to which the plant is very partial. For this reason, soil deficient in lime, or very light soils, should have slaked lime, builder's rubbish or chalk added before planting.

Plants may be purchased at any nurseryman's and put out in April, taking care that the tap roots are planted in a downward direction. Such plants should be spaced at from 9ins. to a foot apart in the clumps or rows, the distance depending on the quality of the soil. Here again, the plant is not exacting. It will grow splendidly on a dry border where little else will thrive, provided lime is present.

Plants are rather expensive and as the blooms are only seen to advantage when massed, it is advisable to raise a stock from seed. A threepenny packet properly sown will yield a thousand strong plants, sufficient to furnish quite a long edging. As the seed is fairly large, it is possible to sow it at intervals in a drill, which will obviate thinning, and make the most of the packet of seed. A piece of good ground should be chosen for the seed bed preferably in a sunny position. Drills are drawn 6ins. apart and 1in. in depth, the seeds being planted some 3ins. apart in the row during the months of April and early May. Subsequent culture consists in keeping the ground free from weeds. Splendid plants are produced by this means, which are lifted in the autumn and planted in their permanent positions.

Producing as it does, two crops of bloom and seed in a season, it stands to reason that some help should be given to established plants in the way of food, if they are to be kept in a healthy condition. Short manure applied in the autumn will mulch the plants and give them the necessary strength to continue their wonderful show of bloom.

When used as an edging, the plants should be inserted at least 1ft. away from the verge or path, the intervening space being filled with aubrietia, which will flower at the same time as the first blooming of the flax, or with nigella for a contrasting blue flower, or the double salmon clarkia, both of which will be in bloom when the second crop of linum appears.

In spite of it being a tap-rooted plant, linum will transplant with ease, even established plants can be divided when they become too large, or transplanted to another position, doing this work in March or April. The roots become broken in the process of lifting, but this has no ill effect on its subsequent growth.—CLARENCE PONTING.

A Rock Garden Gem: Lewesia rediviva.

THIS delightful little flower will prove a gem in any rock garden. It is a dwarf grower, only being about 1in. high, and from a cluster of narrow leaves the flowers grow on short stems, white and pink in colour. They are quite large for so small a plant, sometimes being some 2ins. across. L. rediviva, like all the species, must be grown in full sun, in the very dry crevices of rocks in sandy, well drained soil. It is of easy culture and sometimes the leaves will wither away in the very hot summer, only to revive again with the first rain.

It is best to raise it from seed sown thinly in small pots in the spring and when strong enough planted out from the pots without being disturbed. Its home is in the Rocky Mountains and it belongs to the Portulaca family—R. MOORE.

A Rose Worth Growing: Rosa Moyesii.

OF all the single roses in commerce pride of place can be awarded to R. Moyesii, a charming species introduced from China in 1903. It forms a bush or shrub up to 10ft. or more in height, and is fairly erect in habit and spiny, with dark green pinnate leaves somewhat like those of R. spinosissima. The flowers, about 2ins. or 3ins. across, are borne singly or in pairs on short spurs, the colour being a deep rich velvety crimson, a very taking colour. The beauty of the flower is further enhanced by the cluster of gold stamens. The flowers are followed by curious bottle-shaped, hairy fruits or seed pods, which turn a bright red by the autumn, and at this period of the year it proves a decided acquisition. Those who condemn the wild roses for their short flowering season should remember the autumnal effects of this peerless rose, for such it is, and years after some of the present-day hybrids have passed into the realms of obscurity R. Moyesii will still be held in high esteem by all lovers of the beauties of nature. Perhaps some may have just cause for complaint, because, unfortunately, a number of forms have been placed on the market, these being the result of increasing the plant from seeds.

Here at Castleford, Chepstow, we have fine examples of the original as shown by Messrs. Veitch, also another form with vieux rose flowers, the latter being nearly as good as the type, at any rate it is very acceptable, and proves that R. Moyesii when raised from seeds is a very variable plant. Since it has been discovered that seedlings are not reliable, grafting and budding has probably been resorted to, but we have also raised a few from layers. I have seen it stated that R. Moyesii is readily increased by cuttings, but this is the opposite to my experience, so if any reader has succeeded in rooting, say, 80 per cent., his methods would be welcome to at least one individual.

It should be stated that this rose is not suitable for the prim and proper rose garden. It needs space and freedom where it can extend, and for preference give it a spot where it can be viewed from various angles. It is not too late to plant, and where accommodation can be found buy five or six specimens and place them in a clump a few feet apart. No pruning is needed except the removal of dead wood and the reducing of any branches to keep it within bounds.

Like most roses, this species gives the best results in good soil rather on the heavy loamy side, but it is not absolutely essential, for I know of plants doing remarkably well

Digitized by Google

in what gardeners call "brashy" ground. Such a rooting medium can be improved by adding a little clay and a liberal dressing of partly decayed cow manure. R. Fargesii may be considered a pink form of R. Moyesii for garden purposes.—T. W. BRISCOE.

The Hardy Pyrethrums.

PYRETHRUMS form one of the indispensable features of any herbaceous border worthy of the name, but their usefulness does not cease as worthy subjects for the position mentioned, for they are equally as useful and beautiful when planted in beds, while their value as cut flowers is proved by the quantities which are sold in the florists' shops during the months of May, June and July.

They thrive in any ordinary soil and position, although, like most other herbaceous plants, they delight in a deeply worked, medium loam which has been enriched by the addition of a liberal amount of well rotted stable manure. A rather cool rooting medium is advantageous, but should the soil be very light and sandy the incorporation of cow manure with it will assist in providing the requisite conditions, while a mulch of manure placed about the roots during hot weather will prove decidedly beneficial.

Opinion appears to be somewhat divided as to whether the best results are obtained from autumn or spring planting, but in my experience there is but little to choose between the two, and in wet districts or on heavy soils I would certainly advise that the latter course be followed. In any case there is no doubt that planting can be carried out with safety on any occasion when the soil is in a suitable condition up to the end of February. When planting take care to work some good fine soil in between the mass of fibrous roots so that a good start is ensured. In a border three plants placed triangle fashion will form a good clump; when planting in beds the best effect is obtained by only planting one variety in a bed.

Careful watch must be kept for slugs, otherwise they will devour all the young growth as quickly as it appears. Fine coal ashes spread on the ground around the plants will prevent their depredations and a dusting of soot applied at intervals will act as a deterrent.

The plants are greatly benefited during the growing season if they are given applications of weak liquid manure once a week. When the flower-stems begin to appear some light twiggy sticks should be inserted in the ground so that they will support the rather slender stems.

After the flowers have faded cut them off close to the ground and continue the applications of manure water. In this way a most welcome crop of flowers will be obtained during the autumn.

Pyrethrums are easily increased by division of the roots at planting time. Seed also proves a satisfactory method when single varieties are required.—T. H. E.

A Good Garden Rhododendron.

OF all the many rhododendrons which have been introduced from the East during the last thirty years there are only comparatively few suitable for the small garden, and of that few Rh. Augustinii is one of the best. It belongs to a series in the genus which has taken kindly to the conditions in the gardens, and those who are planting rhododendrons for the first time would be well advised to restrict their selection of rhododendrons to plants of this triflorum series.

This representative is of somewhat twiggy habit of growth, reaching 6ft. to 7ft. in average conditions. The blossoms, borne so profusely every year that it is best to disbud the plant, otherwise all its strength is gradually sapped away, are characteristic of the series to which it belongs. They are rather flat in appearance, with expanded petals and a short tube, and in colour they show extraordinary variation, from a pink and lilac to a form almost pure blue. All forms except that with lilac pink flowers are worth growing. The flowers appear just before the leaves or in a late season the flowering may synchronise with the opening of the leaf-buds during late April or the beginning of May.

RH. AUGUSTINII IS EXCELLENT FOR THE SMALL GARDEN.

In this country it should be given a position which is fairly open and exposed to the sun, at least in all gardens in the north. In the south, however, like many of its relatives, it thrives best in partial shade in a medium to moist soil.

It is a most decorative shrub in spring when wreathed in its mass of blossom, and amateurs need have no hesitation in planting it, as it is a most accommodating grower and will respond to ordinary garden conditions and cultivation.—T.

The Spider Web Plant: Sempervivum arachnoideum.

THIS unique, interesting little plant is not seen at its best when planted on an ordinary rockery; for, although it is quite hardy in most parts of the country, it dislikes rain, and splashes of mud soon spoil the glistening cobweb covering each rosette. The accompanying illustration shows a colony flourishing on a dry rockery. When established this plant gradually spreads over the steep rock face, becoming rather crowded in the process. The rosettes vary considerably in size, and are composed of many leaflets, the tips of which are connected by soft silken threads, so thickly crossed and re-crossed as to simulate the work of an industrious spider. When a rosette gets a larger share of food and space than its neighbours, it increases in size, and the following season sends up a flower stalk about 4ins. to 6ins. in height, bearing a few starry, rosy red flowers which add much to the summer beauty of the plant. It is easily propagated by division, and multiplies rapidly, creeping along the crevices of a dry wall and forming masses over the stones. A native of central Europe and the northern mountains of Spain, it was introduced in 1699, being formerly grown in pots as a curiosity. —J. COMBER, *Nymans Gardens*.

ORCHIDS FOR THE AMATEUR

AT the present time there is a host of enthusiastic amateurs who are owners of a greenhouse which would be found quite ideal for the growing of orchids, and, moreover, the latter would be far less trouble than the miscellaneous collection of plants grown to-day, while the return in interesting flowers would more than compensate the grower for the small initial outlay necessary to furnish the house with suitable subjects. With care, they never need replacing; in fact, the stock will increase, and it will only be necessary to purchase from time to time up-to-date and improved varieties. Probably two slight alterations will be needed with the ordinary greenhouse: first, blinds of No. 2 canvas will be necessary, and the usual open stage must be covered with builders' slates or corrugated iron, on which is placed a thin layer of sifted ashes. This conserves the much appreciated moisture, and reduces watering to a minimum. The temperatures for orchids are: Warm, 70° Fahr.; intermediate, 60° Fahr.; and cool, 50° Fahr.; and for the amateur with only one house o. division the latter is recommended. In such a structure a variety of showy and easily grown orchids can be accommodated with success, the flowering period will extend over the greater part of the year, and, owing to this fact, the repotting will be done at intervals, thereby being very convenient to the amateur who does most of his gardening on Saturdays.

The Slipper Orchids.

For autumn and winter flowering there is a large number of slipper orchids (cypripediums), both species and hybrids, to choose from. First and foremost is the Sanderæ variety of C. insigne, with its primrose yellow and white flowers, and the bold spotted Harefield Hall. The twain are the cream of the insignes, and of the hybrids C. Leeanum in various forms is still in the front rank. A free-flowering, easily grown one is known as C. L. Clinkaberryanum, and a suitable companion is giganteum; both will develop into noble specimens with ten to sixty fine flowers.

In the spring, the chaste Cœlogyne cristata will furnish its quota of white flowers, while for the back or central stage the cymbidiums, with their graceful foliage and arching spikes of blossoms, will continue in perfection for several weeks. The lasting qualities of cymbidiums and cypripediums cannot be equalled by any other orchids.

The Cymbidiums.

A wonderful series of hybrid cymbidiums is now available at a reasonable rate, and two suitable for the beginner are Gottianum and Alexanderi. Among the species will be found eburneum, Lowianum and Traceyanum. A house could be filled easily with varieties of Odontoglossum crispum, of which there are both white and heavily crimson spotted forms. The closely allied odontiodas supply the reddish colours, which are lacking among the odontoglossums. They produce long arching branched spikes, of well proportioned blooms, and are decidedly popular. Three for the amateur to commence with are O. Bradshawiæ, O. Cooksonæ and O. Vuylstekeæ, all more or less marked with red. Lycaste Skinneri will succeed at the warmest end of the house, and Sophronitis grandiflora will thrive in small pans suspended by wires from the roof rafters. The drooping yellow Cattleya citrina may also be tried, but it must be grown head downwards and suspended. The cradle orchids, or anguloas, require the same treatment as Lycaste, and one of the best is A. eburnea; while A. Clowesii should be included. Ærides Vandarum is a choice pure white orchid resembling the hot-house Vandas, and it would succeed if grown on a raft, with a little sphagnum moss and peat arranged between the roots. All the above are worthy of consideration by the beginner or amateur, and if we reduce the number of groups to half a dozen they will be as follows: Cypripedium insigne, cymbidium, Cœlogyne cristata, odontoglossums, odontioda and Lycaste Skinneri.

A Few Cultural Details.

Any repotting should be done when the new growths are beginning to root, and this work will be necessary at intervals owing to the different flowering periods of the plants. Ordinary flower-pots are chosen, and filled one-third of their depth with drainage material, over which is placed a thin layer of rough peat or fibre. The rooting medium consists of Osmunda fibre 3 parts, and 1 part sphagnum moss, to which is added a 5in. potful of crushed crocks to every bushel of the mixture. Annual repotting is not necessary, and over-potting must be avoided, but enough space must be allowed for two years' growth. When a plant is overhauled, the back pseudo-bulbs are reduced to three immediately behind the lead or growing point. Careful watering is essential, and rain-water ought to be used.

Shade and protect the plants from strong sunlight, avoid cold direct currents of air passing over the inmates when affording ventilation, and keep them free from thrips by vaporising the house once every three weeks. The atmosphere is kept moist by sprinkling the floors and stages twice daily during the summer months; but in winter very little damping down will be required.

Give the orchids ordinary common-sense treatment, and success is assured.

T. W. BRISCOE.

THE KITCHEN GARDEN

Practical Tips on Sowing the Seeds.

CABBAGES, curly greens and others of the brassica family should be sown on a rather poor soil if the object is to provide a supply of sturdy seedlings to plant out. If sown on too rich soil the seedlings make a rank soft growth and do not plant out so well as plants that have made a slower growth. One ounce of seed will sow a bed of five or six square yards. Sow in the open in March or April; or in a frame in February.

When sowing peas, remember that 1lb. will sow a row 60ft. long. The same quantity of broad beans will sow a 50ft. row. Kidney and runner beans will plant at the rate of 1lb. to a 70ft. row. Sow in drills 3in. deep. Onions may be sown in rows 10ins. to 12ins. apart, using 1oz. of seed for 100ft. run. Leeks and carrots are sown at a similar rate. But we would advise sowing reliable carrot seed more thinly, if trouble from fly is expected. Sow at the rate of an ounce per 125ft. to 150ft. run, not too deeply, and cover the seeds with sifted soil and sand to a depth of about ½in. Sow carrots in rows 12ins. apart.

Parsnips will require 15ins. to 18ins. between the rows. Sow 1½ins. deep, using 1oz. seed for a 125ft. to 150ft. run. Parsley needs a drill only ½in. deep, 12ins. apart, and 1oz. of seed for 100ft. to 125ft. run.

One ounce of spinach or beet seed will sow a 50ft. run. The same quantity of lettuce and turnip seeds will sow 120ft. to 150ft. run.

The rate of sowing must be governed, it will be understood, by the quality and germination of the seeds, the season, climate and the character of the soil, its preparation and fertility. In a cold district, one must necessarily use more seed, especially if the soil is of a cold and unkindly character. Seeds sown in March rarely produce so many plants as the April sowings, because a larger percentage are likely to prove unfertile or perish. Never sow on a wet and pasty soil. Make the earliest sowings on the driest borders, or on specially prepared plots. It is well to sprinkle some fine sand over the early sown beds, as this helps to prevent the soil from caking on the surface.—J. W.

Dwarf Garden Peas of Merit.

THERE seems a disposition on the part of many who grow garden peas to confine their efforts to dwarf, or, at least, those comparatively dwarf, and to leave out of their arrangements the taller varieties. Every season the requests for dwarf pea seed become more numerous, so that to-day the grower has a number of sorts to select from. When one considers the cost of pea sticks needful for the giant sorts, as compared with prices of ten years ago, it is not surprising that quite a number of gardeners prefer dwarf varieties that only need, perhaps, a few strands of twine running along the row on either side, or fish netting, to keep the haulm off the ground. Apart from this, between dwarf sorts, one may grow other crops without fear that they will be unduly shaded, and the final reason, which weighs with many growers, is that dwarfs mature more quickly, so that one may, by taking advantage of sheltered positions in a garden, be assured of baskets of peas at the end of June or early July. Further than this, by sowing in succession one can continue gathering well on into September in a mild autumn, with more certainty at the back end of the year than is the case when taller sorts are taken in hand. It goes without saying that ground for dwarf peas needs as much preparation as for taller sorts, by deeply digging and manuring, and applying lime as may be found necessary. The owner of the small garden is alive to the importance of making use of every yard of ground, and to him dwarf peas appeal more than tall ones do, which are on his hands a longer time, and do not always bear crops correspondingly heavier. Most firms have their specialities in peas, but there is quite a number of really excellent old sorts that have stood the test of years and are grown throughout the country. Appended is a small selection, most of which are as popular to-day as when they were first introduced:

First Early.—English Wonder, 1½ft.; Peter Pan, 1½ft.; Little Marvel, 1½ft.; Dobbies Early Bird, 1½ft.; Pioneer, 1½ft.; Gradus, 2ft.

Second Early.—Excelsior, 1½ft.; Stratagem, 2ft.; The Daisy, 2ft.; Dwarf Defiance, 2ft.

General Crop.—Sharpe's Queen, 2½ft.; Sutton's Peerless Marrowfat, 3ft.; Veitch's Perfection, 3ft.; Senator, 3ft.—W. L. L.

A Hot-bed: Its Construction and Uses.

TO the gardener who only possesses a frame, or frames, in which to get things moving early, a hot-bed is probably the most useful acquisition in this respect, which can be used for various subjects after the "first earlies" are dispensed with. Two essentials are necessary in making a good hot-bed, *viz.*, the right materials and the correct method to employed in making it up. Good strawy stable litter and either oak or beech leaves, or a mixture of both are undoubtedly the best materials, while careful mixing of the whole, followed by building it up to the required size, treading it very firmly throughout,

Digitized by Google

and, until nearly completed, always keep the "wall" slightly higher than the centre, all these points go towards a really good hot-bed. Whatever size the frame may be, an extra 2ft. 6ins. must be allowed all round, and the depth, 3ft. to 4ft. Assuming early carrots, radish, lettuce, cauliflower, Brussels sprouts and various annuals have been brought along by this method, a crop of cucumbers or even melons could successfully follow, after which violets could reasonably take their place for the winter months

When the bed is not required any further for these purposes, by which time it will be in a well decomposed state, it provides useful material for mixing with potting composts, top-dressing raspberry canes, mulching in hot weather, or may be applied to heavy ground with the object of making it more workable.

These many and varied uses to which a hot-bed lends itself, more than repays the initial cost of making it.—W. F.

Obtaining Quality in Root Crops.

MANY gardeners are now turning their attention to preparing certain vegetables for showing. Whether intended for show or for ordinary use, much may be gained by careful cultivation of crops. The intention of this note is to guide the amateur in the art of obtaining good quality root crops, such as carrots, beet, parsnips and turnips, etc. In the first place the ground must not be of a heavy texture, or such roots as carrots and parsnips will grow forked, as illustrated by Fig. 1, B, such specimens being useless for show purposes. In order to obtain good, well shaped carrots or parsnips, the first digging of the soil must be done deeply. After this, holes are made about 12ins. to 14ins. deep with a heavy dibber, which is well worked about in order to make a hole of fair sized diameter. The holes should be about 6ins. apart for shorthorn carrots, and 10ins. apart for long carrots and parsnips, and long beet should be 10ins. to 12ins. apart. After the holes are thus made, fill each one with good soil, such as potting soil well mixed with fresh ashes from wood. This done, drop three or four seeds at the top of each hole, as near the centre as possible, and lightly cover with a sprinkling of fine soil. When the seedlings are large enough, take out all but the finest specimen plant from each hole. This method certainly takes time, but if quality is desired, as illustrated by Fig. 1, A, it is well worth the extra trouble. The small holes which are left after thinning out should be carefully filled in, since carrot fly often makes use of such openings for egg laying on the root of the remaining plant. A little nitrate of soda will help the plants in their early stages of growth. The same method is employed to obtain good quality turnips or round beet. In this case the holes are best made with a trowel, after which they are filled up with prepared soil, as already stated. In dealing with turnips it is a good plan to sprinkle gas lime on the ground, allowing it to remain on the surface for a week before digging in. Gas lime is good for tending towards ridding the ground of the gall weevil which accounts for the patchy knobs on turnips, resulting in forms such as that illustrated by Fig. 2, B. By employing the foregoing method of sowing—two or three turnip seeds on the tops of prepared holes and thinning out to one per hole—well shaped specimens as illustrated by A, Fig. 2, will be easily obtained.—W. S.

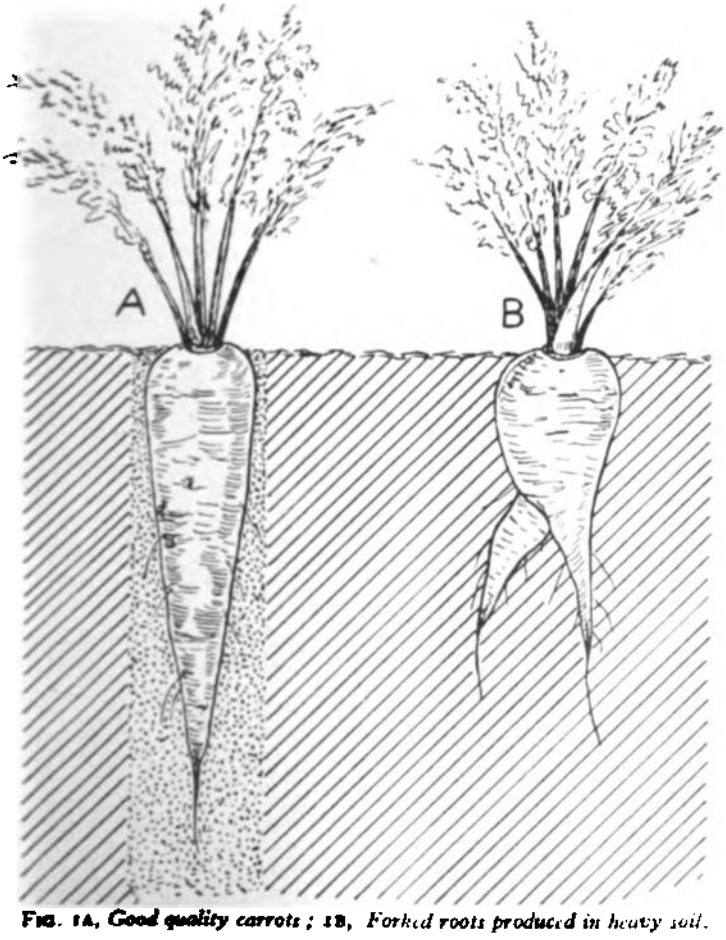

FIG. 1A, *Good quality carrots*; 1B, *Forked roots produced in heavy soil.*

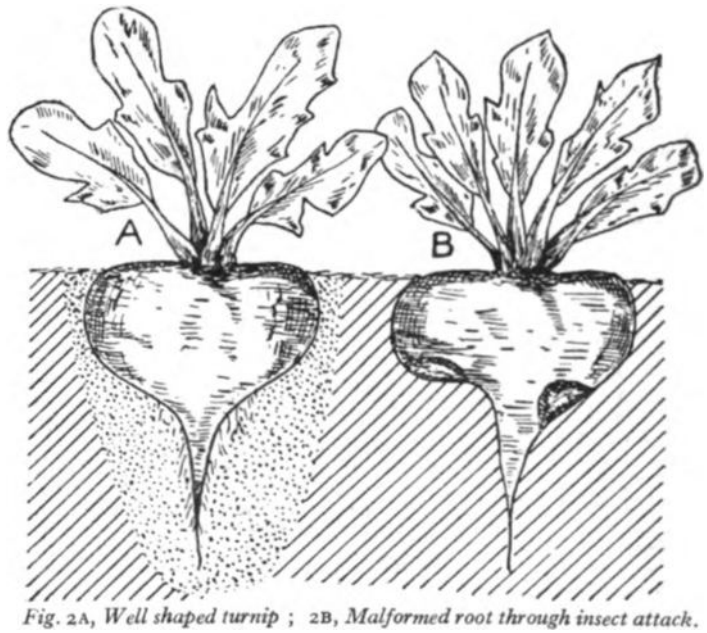

Fig. 2A, Well shaped turnip; 2B, *Malformed root through insect attack.*

Cabbages in Spring.

YOUNG cabbages possessing firm, tender hearts and deep green in colour on the outside always afford the cultivator a great deal of satisfaction. Those who grow cabbages for market do not spare the hoe. About once in ten days, when the soil is dry enough, the hand hoe or the horse hoe is used to loosen the surface soil only. It does not matter whether there are weeds or not, the hoe is used. Soil loosened in this way is warmer, and warm soil promotes early growth; the increased activity of the roots results in a similar increase of growth of the small inner leaves forming the heart of the plant. If this work is done on a large scale, it is equally advantageous to do it on a small scale, as, for the family, an increase in the size of the hearts means greater bulk of food. Nitrate of soda used at the rate of a teaspoonful to each plant twice during the spring, the first application now and the second early in March, will increase the growth of the leaves, improve their colour and the cooking qualities of the hearts. It is better to apply the nitrate in showery than in dry weather. But, in the case of a small plantation of cabbages, apply it as stated and then water it in. Keep the nitrate of soda away from the stems and sprinkle it evenly on the soil round each specimen. Do not drop it in a little heap by the side of the stem, and do not handle hearts intended for showing.—HANTS.

Plant New Shallots.

IT is an old assertion that shallots are one of the most profitable crops to grow, and it is one that will bear the test of trial, for a rod of good land should yield at least a hundredweight of bulbs, and as they have been selling lately at from 5d. to 8d. per lb., the produce from an acre would leave a very large profit.

Shallots require but a minimum of labour, for, planted in February or March on good, well worked ground, 6ins. apart, in rows sufficiently wide to admit of the occasional use of a 4in. Dutch hoe for keeping down weeds and stirring the surface, nothing further need be done until the bulbs ripen, generally about the end of June. Plenty of soot and wood ashes should be spread thickly over the surface of the soil, this will afford much protection against both rain and frost and help to prevent the latter from drawing the bulbs out of the ground.

Shallots are of much more general use than garlic, being less offensive in smell, and are used in soups, salads and other culinary preparations; while for pickling they are preferable to onions, being milder and of more delicate flavour. If, when the bulbs commence to grow, they are lifted by worms or frost, the soil around them should be pressed and made firm. After they have become fully established and well rooted, it is a good plan to draw the loose soil away with the hands, so as to leave the bulbs fully exposed, thus tending to prevent mildew and canker from setting in. When the tops turn yellow and wither, the clusters of bulbs should be lifted and spread out to dry thoroughly, after which they may be hung in nets, or stored in any airy room or loft.—R. D.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE successive "blasts of Janwar wind" which swept over Scotland in the closing days of the month left a deplorable record of havoc in their trail and forcibly postponed all early attempts at gardening to a later and more congenial season. As the ground is very wet some time must elapse before it is in a fit condition for digging, and a spell of dry weather accompanied by a few degrees of frost in the mornings would therefore meet the requirements of most amateurs. The days are stretching out quickly and by the end of February there should be sufficient daylight to permit of a little outdoor work in the evenings.

Meanwhile, there is no need to be idle, for there are several things to occupy attention and which may be accomplished in the greenhouse on a Saturday afternoon or in the cosy surroundings indoors in the evenings. Perhaps the most important work in February is the sowing of sweet peas. These indispensable annuals are sown in autumn for exhibition purposes, but the general and most satisfactory practice for ordinary garden work is to sow the varieties this month in pots or boxes and germinate them under glass. When grown on under cool conditions in a frame strong sturdy plants are available for transplanting in the open some time in April, and in a normal season the first blooms should be ready for cutting in early July. When a small collection, say up to twelve varieties, is to be raised, pots containing one to five seeds, according to the size of the pot, are most convenient; but I raise on an average thirty varieties annually and find that boxes of not less than 6ins. depth are more suitable for raising large quantities.

It is a common mistake on the part of sweet pea growers to make the soil too rich. This should be avoided, because it is neither necessary to the germination of the seed nor the growth of the seedling. All that is wanted is sufficient food to maintain it until transplanted in the open ground where the young plants will readily respond to the nourishment that has been provided for the production of foliage and flower.

Another point. As regards the necessity of chipping black or dark skinned seeds, such as the crimsons and maroons, considerable diversity of opinion exists. There is much to be said in favour of a simple operation which is undoubtedly followed with satisfactory results, but in the past five years I have obtained a total germination ranging from 91 to 96 per cent. without chipping the seeds before sowing. By germinating the seeds in gentle heat and providing an inch thick layer of sand on the top of the soil the risk of decay arising from too much moisture is reduced to a minimum, and few indeed are the losses which occur from that cause. When germination has taken place, I search each vacant space with the aid of a pocket knife until the seed is found. Generally speaking, the conditions which account for the non-appearance of the young growth on the surface are twofold—the seed has either germinated and grown downwards or it is found in as hard and sound condition as it was at the time of sowing. In the latter case a tiny portion of the skin is removed from the side opposite the "eye" and the seed put back in its place, when it germinates a little later than the others. Readers who possess means of supplying artificial heat should give the system a trial, but in the absence of warmth at this season of the year it is better to chip all dark seeds before sowing. When the seedlings have reached a height of 1in. to 1½ins., the boxes should be transferred to a cold frame and the plants grown on under cool conditions by gradually raising the sashes until they are removed altogether, only to be closed in very wet or frosty weather. On the appearance of two, or at the most three, pair of leaves pinch the top of each seedling. This will promote the growth of the lateral shoots and contribute to the production of strong bushy plants.

March is the earliest time in which culinary peas can be sown in the open ground in Scotland with reasonable prospects of success, and a simple calculation will show that the resultant produce should be ready for use about the middle of June. Cropping, however, can be accelerated to the extent of a month by sowing an early dwarf variety in boxes placed in a cold frame just now. The method of culture is very similar to that advised for sweet peas, and in small gardens with limited frame accommodation it will be found convenient to grow the two kinds together. Birds and slugs are the principal enemies, and it may be necessary to provide some form of protection from the one and a careful watch for the other.

Make firm by treading the soil surrounding the stems of rose bushes, and earth up spring cabbages, as the plants have become loosened by the forceful action of the recent gales.

ST. MUNGO.

WHAT OUR READERS SAY

WOODLICE IN GREENHOUSES.

SIR,—Some readers of THE GARDEN have been asking how to rid greenhouses of woodlice. Many gardeners also keep poultry. Where it possible to clear the greenhouse of all plants is and put a batch of young chickens in for a few days, the chicks will find and devour all the woodlice. This method of clearing the pest was tried here with great success during the spring of 1926. I found that soil fumigants had very little effect on woodlice. Another, though rather tiresome, method, but very effective in reducing their numbers, is to lay slices of potatoes or turnip down on the greenhouse beds. Examine the under sides of these each day, when many will be found, and can be crushed.—J. H. HARDSTAFF, *Northallerton, Yorks.*

THE TEMPTATION TO SOW OLD SEEDS.

SIR,—With reference to the note headed "The Temptation to Sow Old Seeds" (which appeared in your issue of January 8th), the writer enunciates three questions for consideration. To these three questions I now venture to submit three specific answers.

The questions which the writer states "naturally arise" are these:

(1) Are we ever justified in using old seeds in preference to buying new?

(2) Supposing they germinate, will they give just as good results as fresh seeds?

(3) Is it a paying proposition to make shift with old seeds?

The writer goes on to say that "These are questions which cannot be answered in the negative or affirmative without qualification, etc."

There is obviously much truth in the latter statement, but I, nevertheless, maintain, and doubtless you will yourself agree with me, that these three questions can and should be answered categorically and specifically by every really experienced gardener, somewhat as follows:

(1) Yes.

(2) Undoubtedly, where old seeds are preferable to new ones.

(3) Yes, where old seeds are preferable to new ones. In all other cases, No.

The reasons for these answers are apparent when we remember that parsnip seeds retain their full germinating powers for two years; carrots, leeks, onions, parsley, peas and salsafy for three years; beetroot, spinach beet, brassicas generally, mustard and cress, lettuces and round spinach, for five years; celery, cucumbers, endive, marrows and melons, for six years. It is, in fact, a mistake to use melon seeds of less than from three to five or even six years old, the idea being that the plants obtained from new seeds are usually so rampant in growth that they mostly fail to produce fertile blossoms, whereas the older seeds give plants of greater refinement and produce any amount of flowers of both sexes. Tomato seeds will retain their vitality for as many as nine years.

There can be little doubt as to the age of seeds obtained from any reliable seedsman, as the date of harvesting is clearly stated on the packets supplied. This, then, solves the whole matter, and automatically answers all three questions. It might be of interest to readers to know this.

Similarly, the question as to whether or not it is desirable to buy new flower seeds every year is automatically answered by knowing the length of time each particular kind of seed can be relied upon to retain is vitality, without in any way losing its germinative power. So far as I am aware, scarcely any flower seeds usually in demand are any good after their second year; in fact, the only ones for which I can vouch as being good for so long are sweet peas, balsams, wallflowers, tuberous-rooted begonias, stocks, cinetarias, gloxinias amd streptocarpus. The Persian cyclamen, however, gives best results from seeds over two years old, and home-saved seeds of Celosia plumosa have been known to germinate after eleven years. The above are the only exceptions at present known to me in the way of flower seeds which do not require renewing every year.—E. A. SAUNDERS.

SWEET PEAS AND STREAK.

SIR,—The letter from "C. H. W." in THE GARDEN for Feb. 5th, recalls a letter of my own which you published some months ago dealing with this subject. My object in writing was to collect as much information as possible dealing with this disease, to see if we cannot get down to something concrete as to its nature, cause and conditions that encourage it; and, finally, in hope that measures may be found to combat and, if not to exterminate, at least to control it and keep it down. Surely this is not an impossibility with the means that we have at our disposal to-day.

The result of my letter was not what I had hoped for, but I certainly received encouragement by a visit from a prominent gentleman in the sweet pea world, who is keenly interested in the subject, but as much in the dark about it as myself; but we mutually decided to carry on investigation, which I have already started upon.

In my letter I did not mention every detail that might possibly have bearing on the matter, because I had hopes that shoals of letters would have appeared and that other growers might have mentioned conditions similar to my own, which might form a basis on which to work. I had waited in vain until the letter of "C. H. W." appeared. His experience

Digitized by Google

coincides with mine. On enquiry from other sources the answer is the same as that which he quotes—very little is known of the disease; we know its effects! I am afraid this will not help "C. H. W." very much, but trust that his letter may have the effect that we both desire.

It is to be hoped that those in the position to do so will seriously take the subject in hand. I will not believe it to be insurmountable, and surely it is serious enough to merit determined and definite action. I am out to do my bit towards it, but must confess to being very much in the dark at present.—C. H. H., *Twickenham.*

CORNFLOWERS AND SHIRLEY POPPIES.

SIR,—What will do in one garden—or with one gardener—will often not do in another garden—or with another gardener. Hence may I suggest that it is not wise to make such positive statements as "it is not possible to transplant Shirley poppies" (page 81, THE GARDEN, February 5th, 1927), and on page 82, "the cornflowers particularly resent transplanting."

For more than twenty years I have sown in the autumn, in a seed bed, outside, blue cornflowers and Shirley poppies. In the spring both were transplanted to the borders. The poppies had to be handled carefully, choosing a suitable day, etc., but with a little care I never had any difficulty. The cornflowers gave no trouble at all and I have often given them away to friends to plant in their gardens. Both cornflowers and poppies did well and made fine bushy plants. This is in the south-west of Scotland, inland, 300ft. up.—H. M., *Dalbeattie.*

NOVEL GARDEN PATHS.

SIR,—In your issue of the 8th ult. you have a very interesting article upon garden paths. Thinking it may interest many of your readers, I enclose illustrations of three separate paths I put down in my own garden last spring.

No. 1.—Originally this was a cinder path with the usual tile edge, but being upon the slope the ashes washed away badly after storms. This I paved with cobble stones about five years ago, the centre being across the path, but, being uncomfortable to walk upon, I pulled the centre up last spring and filled it in as shown. The bottom two oblong slabs are brown silica, the following are grey and red sandstone up to the circular stack stone.

A PATH FORMED OF SLABS OF STONE EDGED WITH COBBLE STONES.

AN OLD STACK STONE HAS BEEN INTRODUCED HERE.

No. 2.—Another path. Note the old stack stone with the yellow circular slabs surrounding it.

No. 3 is upon a slope, and coloured stones hold the narrow border up. The centre is filled with slate slabs, bricks laid in various patterns and a few tiles.

Getting the material together was very interesting work, cartage being the most expensive item. Eighty square 24in. red sandstone flags were purchased from an old manor farmhouse when they were taken up from the entrance hall and several circular stack stones at a cost of 40s. Twelve tons of "cast" blue and brindle slabs with a large number of bronze and yellow silica, several brown glazed pig spouts and sinks were purchased at 1s. 6d. per ton from a waste heap at a brick works, about the same weight of grey and red sandstone and broken concrete slabs were obtained from a closed builder's yard at 3s. per ton, and several stone and slate mantelpieces and shelves from the same source at a cost of a few shillings. Bedding the material was heavy work, but it was done with the knowledge that it would not require to be carried out a second time.—WATKIN SAMUEL, *Wrexham.*

MAKING A NEW GARDEN.

SIR,—In the examples of garden making which have been an interesting feature of recent issues the starting point seems always to have been a piece of ground rectangular in shape and of even surface (whether level or inclined) *in a condition suitable for immediate planting.* These advantages one may find if one buys land properly developed for building, or when a plot of arable or old pasture land is in question. But the business of garden making is neither straightforward nor easy when the land one buys, for want of better, is oddly—say triangularly—shaped, consists of rough grassland not free from nettles and other undesirables, slopes steeply and irregularly from end to end, and has a deep central depression from which, presumably, chalk was dug long ago.

Such is the writer's unenviable position, and he would very much like to know from any interested readers how he should set about ridding the ground of the coarse grass and rampant weeds, as presumably he must do before starting to plant shrubberies, shade trees and fruit trees—with which, in the main, he proposes to fill his acre, leaving space near the house site for rose walks and flower borders. Having had to pay a high price for the land, its conversion to a better state, before planting, must be effected as cheaply as possible.—NORTH HERTS.

THE CLIMBING GENTIAN.

(*Crawfurdia trinervis*).

SIR,—I was much interested in Mr. K. Yashiroda's letter on this plant and believe that he is correct when he says that it is practically unknown in English gardens. It may interest readers to know that this pretty plant is grown at Burford, Dorking, in the gardens of Sir William Lawrence.

I saw a few plants there last summer in small pots. They are given cool house treatment and are quite effective when bearing their purplish red fruits. I believe the plants mentioned were supplied by the Yokohama Nursery Co., Japan.

Crawfurdia trinervis is not mentioned in the Kew Hand-lists, nor can I find it offered in any seedsman's catalogue.—F. W. THORUS, *Kew.*

TRAPPING MICE AND VOLES.

SIR,—In your issue of December 11th last, you had an article on trapping mice. The methods described are doubtless effective enough to deal with the ordinary mouse. He and his family appear more or less as single spies; but the short-tailed mouse, which is, I believe, a vole, is in the other category, and comes in battalions. How is one to deal with him? Can any of your readers suggest anything more practical than encouraging owls and hawks, which I have been told to do, in the way of wholesale extermination. Poison gas does not seem workable, for these creatures appear to be up-to-date, that is, of a very restless disposition—always boring into fresh corners. My cat catches more than she can eat; I catch a few in traps, and there are owls in the vicinity. But the mice have the upper hand of all of us.

I shall be very grateful if any of your readers can give me some practical suggestions for destroying these pests, which do such harm to the crops in my garden.—W. P. PECHEY, *Brent Knoll, Somerset.*

COLOURED STONES, SLATES AND BRICKS, HAVE BEEN USED FOR THIS PATH

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Preserving Plant Labels.

It is a common experience that the action of damp soil soon makes the usual wooden plant labels quite illegible. The life of these may be considerably lengthened by following this method: Coat the labels with a good quality white paint, and before this is quite dry write the name of the plant. Put aside until thoroughly dry and then dip the entire label in shellac. The shellac when dry forms a transparent film which protects both the writing and the part of the label under the ground. A label thus treated will remain useful for two or three years.—W. A. W.

Top-Dressing Gentians.

Many fail to grow gentians, such as GG. acaulis, verna, sino-ornata, Farreri and similar species with any degree of success, and to those who have failed the following treatment is recommended: At this season the growths of G. acaulis are well above the soil and, consequently, are easily disturbed by the wind. Such patches should be cleared of weeds, the top soil lightly pricked over, and then given a top-dressing of leaf-mould and grit. Work it well between the growths, make it firm, and when the job is done the shoots will just show through the soil. In May the result will be seen in healthy, strong-flowering shoots. G. verna responds well to this treatment, and miserable specimens become a healthy mass in a few years. Both G. Farreri and G. sino-ornata are on the move, and these will benefit by a top-dressing now and another a few months hence. The chief point is to make the soil quite firm and get it well down between the growths.—S.

Increasing Choice Delphiniums.

Many amateurs are unaware that the best way to increase delphiniums is not by division, but by cuttings. These should be taken when the new shoots have made a growth of about 4ins. Fill a cold frame to a depth of about 6ins. with a compost of sifted loam 2 parts, leaf-soil 1 part, and sand 1 part. Firm down, leaving about 6ins. of head room at front. Sever the cutting near the stock and plant 2ins. deep, first dropping a little sand in the hole. Water well and shut up close for a fortnight. They will soon root, and may be allowed to flower, but not to seed. Transplant the following spring.—J. F. H.

Coltness Gem and other Choice Dahlias from Cuttings.

Cut old stem of tuber about an inch from crown, place tuber on 2ins. of leaf-mould, partly pressing them into it; have them on hot-bed, as bottom heat is essential both for starting tubers and rooting cuttings. When shoots are from 2½ins. to 3ins. long is the best time to take the cuttings. Sever the shoots as near the crown as possible, taking care to leave a small piece on crown, where others will start from. Cuttings this length are solid through; longer ones are often hollow and are useless. Compost for cuttings: 2 parts moss litter (passed through ¼in. sieve) 1 part silver sand, and layer of sand on top. Insert cuttings firmly, give a good watering, and *do not* cover with glass. Pot on, when rooted, into 3½in. pots. Fifteen plants per tuber is a small average by above method. All dahlias can be treated likewise.—G. McG.

Checking Carrot Fly.

In addition to advice given in your issue of January 29th: (1) *Never* thin or weed carrots except after rain; (2) Use the Dutch hoe once a week between the rows; (3) Scatter old soot around the young plants; (4) In prolonged dry weather spray young carrots with weak "Abol" solution.—E. M. W.

Light in Greenhouse.

After fumigation, the greenhouse glass becomes dull. It is imperative that this blueness or smoky film be removed in order that the young plants may get full benefit of all the light. If an eggcupful of methylated spirit be added to water used for cleaning the glass, it will not only expedite the work, but prevent the glass from getting into the same state for a considerable time. A trial will convince the sceptical.—T. H. H.

Trained Trees on Walls.

Possessors of new houses who decide to grow peaches, apricots, pears or other trees against the walls are strongly advised to begin by having four or five wires firmly fixed about a foot apart. The cost is small and it saves an infinite amount of time and temper afterwards. When shreds are used these soon rot and a rough wind tears the nails out, so that much time is spent replacing them, and both tree and wall are often damaged. With wires laying in new wood and keeping the tree trim and shapely is quite a simple and pleasant job.—K. B.

Raising Begonia and Gloxinia Seed.

Place some loam in a baking tin or something similar and place on the boiler fire to bake. It is an advantage to let the lower soil become burnt, as it is suitable food for seedlings. Then get some flaky *wet* leaf-mould and allow it to get very hot. I treat the sand the same. Pass loam through an ¼in. sieve and leaf-mould ¼in., then mix in equal parts, adding sand. The day before sowing place enough 48 size pots in water to soak all day, drain them off at night. Fill pots to within 2ins. of the top with crocks, place a little rough siftings over and 1½ins. of prepared soil, water with rose can to settle the soil. About an hour after, sow the seed, first mixing a pinch of sand with it to sow evenly. Two days after sowing dip the pots in warm water level with the soil *only*. Repeat this in a week, and if placed in a propagator I always look for germination in ten days, and am not disappointed. A piece of glass should be placed over pots and shaded with paper. The object is to keep the soil *very wet*, and the baking prevents the soil becoming sour—keeping good six to eight months. From a 2s. 6d. packet of Blackmore and Langdon's gloxinia seed last year I raised 300 seedlings in this way.—S. H. C.

GREENHOUSE NOTES

Pentstemons from Seed.

PENTSTEMONS make an effective display in beds and borders, and the flowers are suitable for cutting. From a good strain a variety of colours may be expected. Some may be worth preserving, and there is also the possibility of securing a form of special merit. Plants for flowering in summer and autumn may be raised from seed sown immediately and the seedlings treated in the same way as half-hardy annuals. They should be transplanted into boxes when large enough to handle, allowing room for them to develop freely till ready for planting out towards the end of May or early in June, after being hardened off in the usual way in a cold frame.—J. C.

Petunias from Seed.

PETUNIAS have always been popular plants in cold greenhouses, in cottage windows, in summer hanging baskets and, where conditions are suitable, in the open border. One reason for that popularity is that they are easily raised from seed and a note on the work is opportune, for the sooner the seed is sown the better; raised now, they will furnish bloom from June until the month of October. Fill a seed pan with good compost, consisting of loam, leaf-soil and sand, and let the surface be fine sifted stuff. Water, and after mixing the fine seed with sand or flour scatter it as thinly as possible over the surface; the smallest sifting of soil is sufficient to cover this seed, indeed some growers leave it uncovered. Treat this seed pan and subsequent seedlings like the others at present in the greenhouse, but, before the little plants become too crowded, transfer them to other boxes, if for bedding out, or into small pots if for greenhouse decoration; ventilate freely, keep near the glass and at the end of March or early in April, get them into the frame. Those in pots may, however, remain inside, being potted on in due course until they reach the 6in. size in which they will flower. Plants for outside may be kept in the frame until the beginning of June. Pinch all plants once, in the seedling stage, to promote branching. Ordinary single-flowered varieties are popular for bedding purposes and a fine range of colours is available; a compact-growing strain, which is only half the height of the former, is particularly fine for edgings and for filling pockets of the rock garden. Double varieties find more favour as pot plants, but they are equally good in the open; I might remark here that the smallest seedlings, apt to be overlooked, frequently become the finest plants eventually. A word in closing—most readers will need but a few plants and I urge the very best seed, even if it may be a trifle costly.—CLYDESDALE.

Gloxinias.

GORGEOUS greenhouse flowers, the gloxinias are usually raised from tubers or from seed. The former plan is rather expensive, for the tubers are fairly high in price, but it is a fine method of keeping up a succession; tubers are started, like begonia tubers, from the beginning of January, in successive lots and flowers can then be had early in summer and continuously. From seed, which should be sown this month, flowers are obtained later and, in this way, a long season of growth is secured. Shake out old tubers from their spent soil and place them in trays containing equal parts soil and sifted mould, the tubers merely resting on top. In the greenhouse, place this tray in a warm corner near the pipes; if a good high temperature (about 65 degrees) is not certain, put the tray in a warm propagator in which the air is kept moist; ventilate carefully to prevent the tubers from rotting. When 2ins. of growth develops, pot up singly in the same compost and still keep them in the same warm moist atmosphere. Shift them on two sizes

Digitized by Google

and still again, when they will develop flower buds; when the first bloom expands let them stand out in the greenhouse, even where the temperature is much lower. Seedlings are raised exactly like begonia seedlings, in a warm and moist atmosphere (again about 65 degrees to 70 degrees). Great care is necessary in watering, the best plan being to dip the box into a tank of tepid water until the soil becomes damp; turn the glass over every day, to ventilate the plants. Prick out into other boxes and pot up singly when they become crowded, always keeping them in the same warm and moist atmosphere. We might add here, lest beginners be disappointed, that seedlings only flower late in the season and, then, not satisfactorily. The plan, however, is to keep the tubers throughout the winter, keeping them nearly, but not quite, dry all the time; pot up the tubers the following year as directed above and a wealth of blossom will be the result. Beginners can start with tubers just now or sow seed at once—good seed, remember.—LANARKSHIRE.

How to Grow Cannas for the Greenhouse and Garden.

THE canna is one of the most useful of all fine-foliage plants for the amateur to grow in pots in the greenhouse and also in the flower garden. In addition to the handsome leaves, the plants resultant from seeds of the newer varieties bear stately spikes of flowers, somewhat resembling those of the gladioli. Unlike the last named, cannas, when the flowers have faded, retain for a considerable time their beautiful leaves; they never are weedy or shabby in appearance in the flower garden. The seeds should be sown now in a good, loamy compost and, if possible, subjected to a mild and constant bottom heat. The seeds vary a little in shape, some being round and others almost oval. They are extremely hard and sometimes remain several weeks in the soil before germination takes place. Soaking the seeds in tepid water—

kept in the greenhouse—for two days, will soften the skin. The latter may be gently filed, as shown at *b* in the sketch *a*, the germ not being touched; this is very important. When sown quite 1in. deep and the same distance apart, in pots or pans, the soil must be maintained in a consistent state of moisture. Old roots should be started now by potting them separately in small pots. Leave the crowns, *c*, just clear of the soil *d*. When the roots, *e*, are growing and have reached the bottom of the pot, *f*, repot for greenhouse decoration, first into *g* and finally into *h*—a 7in. pot. The new growing crown *i*, must not be injured or the flower spikes may be malformed.—CHRISTCHURCH.

Raising Broad Beans Under Glass.

A REALLY early crop of broad beans is much appreciated, but the hopes of the gardener in this direction are not by any means always fulfilled. It is the usual practice for the earliest gathering to sow the beans out of doors in mid-winter, and so hardy are the plants that they rarely suffer from the effects of frost. On the other hand, snow, which may come on any day, often does a great deal of damage to the seedlings. In fact, after a fall of wet snow the young bean plants frequently die away altogether and those that remain are in such a poor condition that the crop is sure to be indifferent. It is really worth while raising the beans for the earliest cropping under glass. Here the plants will be able to grow on without any check, and by the time planting out comes they will be in an exceptionally robust condition. Quite a moderate-sized box filled with light fine mould will hold enough bean plants to occupy a good plot of ground. Fill the box to about two-thirds of its capacity with soil and then place the beans out, leaving about an inch and a half between each. Then cover with soil and, if this is moderately damp, no further watering will be needed. Broad beans in a water-logged soil rot very quickly, and this is often the cause of failure in outdoor planting. The box may be kept in a cool greenhouse or a frame, and there is no special advantage in having any heat. Of course, with a little warmth germination is more speedy, but as soon as the seedlings are up, the box should be removed to a cool place. Then a position close to the glass is essential, as it is most important to prevent the seedlings getting at all drawn. Planting out should be done from the beginning to the end of March. This is easily done by drawing a wide deep drill or setting the plants by the side of the line with a trowel. Lift each little plant with as much soil round the roots as possible, so that the removal may not impose too serious a check on growth.—S. B.

Some Hints about Seed Pans Boxes and Pots.

BEFORE we can possess satisfactory batches of plants to furnish our conservatories, greenhouses, and, in certain cases, beds in the flower garden, we must nurse them from the seedling stage onwards. This means obtaining a stock of pans and boxes suitable for the sowing of seeds and the rearing of seedlings. Pans and pots are, usually, quite safe as regards any fungus growth. Boxes are not, especially those that have been used in previous years. All vessels, therefore, should be quite clean, especially on the insides. Furthermore, the pots and pans and also all crocks used for drainage, must be dry when used. Boxes should be stored in a dry shed and the insides painted freely with hot lime-wash at the time of storing. If that was not done, then you should lime-wash them at once. Now, we will consider how these receptacles should be used, taking flower pots first. At

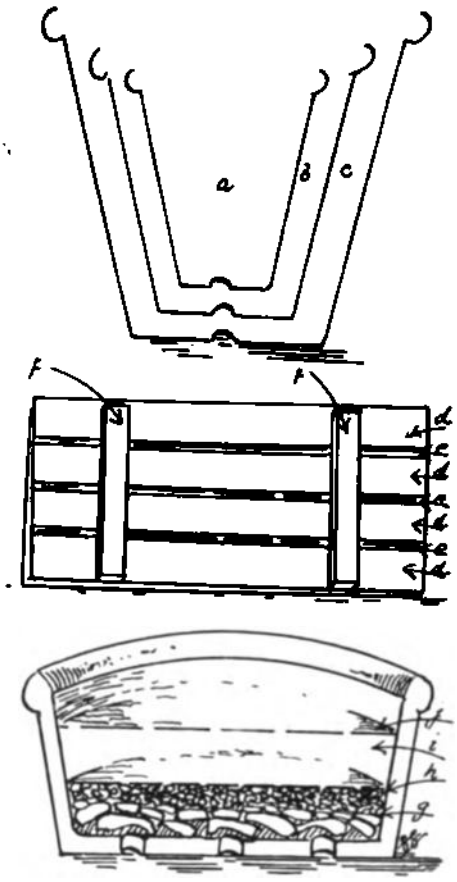

Fig. *a*, a small pot is shown. A young plant in such should be potted on into size *b* and, in due course, to size *c*. These repottings are the usual ones that an amateur does during the summer months, flowering the majority of his pot plants in size *c*—a 6in. pot. The bottom of a box is of the most importance; *d*, *d*, *d*, *d*, represent the boards with a small space, *e*, *e*, *e*, between to ensure drainage. This is a better plan than making round holes. The crossbars, *f*, *f*, bind together the boards and preserve them from a damp base. The seed pan is prepared as shown, namely: *g*, drainage material, *h*, rough compost, *i*, fine compost, and *j*, a level surface to receive small seeds and far enough from the pan's rim to allow resultant seedlings room in which to grow under any covering glass placed on temporarily.—GEORGE GARNER.

The Orchard House.

CHERRIES, apricots and plums are best grown in large pots, so that they may be removed to the open air for a time after the fruits are gathered. The house, in the meantime, can be used for something else. Of course, fruit trees in pots do take up considerable space, but an ordinary-sized house will accommodate one or two specimens of each kind. The present is a good time to purchase the trees in pots, as they have been properly wintered by the nurseryman. The trees of the kinds named above should be subjected to a mild artificial heat now. It is only necessary, at first, to keep the ventilators closed and to syringe the branches each morning when there is no frost, and on bright days at noon as well, so that the buds may be softened and the young shoots grow more kindly. When the first few leaves form on the shoots syringing should cease. The necessary atmospheric moisture can be obtained by damping the path and borders.

Peaches, nectarines, pears and apples should be placed in the orchard house now.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Plants for a Rockery in Semi-Shade.

I shall be much obliged if you could suggest some suitable plants for a small rockery situated near the north wall of my bungalow—it gets a little late afternoon sun in summer and is otherwise cool. Soil is clay, with gravel drainage below. The plants would not have to be too rampant, space being limited. Naturally, I prefer, if possible, to have varieties which will not all be in flower during the same season of the year.—L. B. F., Southend-on-Sea.

We give below a list of plants which would be suitable for a rockery such as you possess: Saxifraga umbrosa, S. ligulata speciosa, S. hypnoides, S. decipiens grandiflora, S. d. sanguinea, Campanula Portenschlagiana (Muralis), Myosotis alpestris, Primula japonica and P. Bulleyana, Anemone blanda and A. nemorosa, Aquilegia alpina, Epimedium pinnatum, Gentiana septemfida and G. asclepiadea, Polygonum vaccinifolium, Viola cornuta, Pulmonaria azurea and P. saccharata, Polygonatum latifolium, Helleborus orientalis, Corydalis lutea, Meconopsis cambrica, Anemone Hepatica, Trillium grandiflorum.

The Care of Plumbago capensis.

Three years ago I planted a young Plumbago capensis in a 5in. pot in a greenhouse from which frost is excluded. The plant has grown vigorously with three stems some 12ft. long, with side shoots both numerous and long, but it has not shown the slightest indication of bloom. Can I do anything to make it bloom.—W. F., Birmingham.

We cannot understand why your Plumbago capensis does not flower, as this plant usually flowers freely, even when quite small. The side shoots should now be pruned back to within two or three eyes of the main shoots; the subsequent growth made from them should flower this season. The main stems should be staked out to allow plenty of light and air to get to the growth. The plant would also benefit by being moved into a larger pot, say 8ins., as a 5in. pot is really too small for the size of your plant. The best time to repot it is when it has just started into fresh growth. Although fine specimens can be grown in large pots, the plant is seen at its best when it is planted out in a bed or border, and the shoots trained up under the roof glass.

A Quick Growing Climber for an Exposed Site.

I should be obliged if you would tell me of any suitable evergreen climber, quick grower, to cover a trellis about 7ft. high. The soil is heavy loam and the screen faces north-west, but is in a very open position. If possible I should like something that will grow with climbing roses, as at present there are a few planted here. Something rather close is wanted to shut out a bad view.—J. F., New Milton, Hants.

We suggest that you try Lonicera Halliana, which we think will be very suitable for the position you mention.

Shrubs and Climbers for a Small Front Garden.

Our front garden is only small, about 20ft. by 16ft. We have privet surrounding it, with a golden yew 18ins. high in the centre of a grass plot. While we do not want to overcrowd the small space available, we thought that four small evergreens at the corners would be an improvement and have considered silver euonymous for that purpose; the uneven wandering growth of the specimens obtained would not, however, fit in with our scheme. Can you suggest any slow-growing evergreens which might be suitable? We do not favour boxwood. Can you suggest a self-clinging evergreen to grow up a rough-cast wall facing north, please? A flowering evergreen would be preferred. If there is any difficulty about this, could you give the names (with colours) of any suitable variegated ivies?—A. D., Edgware.

We suggest that you plant Cupressus Fletcheri in the four corners to which you refer. There is nothing self-clinging that would grow up a wall facing north. We suggest that you try the following: Hedera Helix angularis aurea, H. H. Sheen Silver, H. H. Lee's Silver and H. H. hibernica maculata.

Compost for Maidenhair Fern.

Will you tell me how to make up a suitable compost for maidenhair ferns?—F. A., Shrewsbury.

Maidenhair ferns grow best in a compost consisting of two-thirds fibrous loam, the other third being made up of good leaf-mould and well decayed manure to which fibre and coarse sand have been added. The loam should be broken up into a lumpy condition, but should not be sifted. The leaf-mould, on the other hand, should be sifted to take out the rubbish. The compost should be pressed fairly firmly about the roots of all plants, but less tightly about those which are quick growing. They are best repotted about the month of March, when the young fronds are being produced.

Climbers for a Bungalow Wall.

I want to grow various climbing plants on each wall of my bungalow, and have already bought three white jasmine, two yellow jasmine, two Virginian creepers and one Clematis montana. The walls of the bungalow are about 20ft. long. This bungalow village is situated on an alluvial flat exposed to the south-west wind, and the south side of my bungalow is draughty at times and partly shaded by my neighbour's bungalow. Could you please let me know whether the climbers I have are too many and which plants are most suitable for the different sides? Is it true that climbers are apt to make the rooms damp? The bungalow is built of concrete.—E. C., Uxbridge.

We advise you to plant the climbers you have bought in the following positions: South.—Clematis montana, one white jasmine. North.—One yellow jasmine, one Virginian creeper. West.—One white jasmine, one yellow jasmine. East.—One white jasmine, one Virginian creeper. Being built of concrete, climbers will not make the walls of the bungalow damp, and there should be ample room for the eight climbers. You can prune accordingly.

Pampas Grass and its Needs.

Please give cultural information about this plant and say whether the flower fronds should be cut or "pulled," and, if the latter, when. Would the plants be injured by removing the flower stems as soon as the bloom is fully developed?—F. C., Flitwick.

The pampas grass thrives best in a deep, rich loam, preferably on a gentle slope facing south and sheltered from the north and east winds. While growing, plenty of water is required. The flowers—plumes—should be cut just before autumn frosts. Dried leaves, settling near the centre of the clump, should be removed, as they choke the plant if left year after year. In a prolonged spell of severe frost, wrap mats round the clump.

Pruning of Clematis.

Will you kindly tell me how to cut back the following clematis, and also the correct time to undertake the work: 1, montana; 2, rubra; 3, Jackmannii; 4, lanuginosa; 5, Lady or Beauty of Lyons; 6, Nellie Moser.—E. C. S., Bristol.

(1) C. montana should be pruned immediately after flowering in May. Var. rubra should be treated in the same way. (2) The one you call rubra may be Proteus; thin out, removing weak wood and cutting off old flowering wood on which there are no young growths after flowering, which will be about August; remove very thin ends of long shoots in February. (3) Jackmannii should be pruned hard in February, cutting back all last season's growths to within 6ins. of old wood. (4) C. lanuginosa: remove weak twigs in February and shorten the thin ends of very long growths; cut out old pieces on which there are no young growths. (5) This may be Ville de Lyon, with carmine red flowers; prune and thin fairly hard in February. (6) Nellie Moser should be treated in the same way as lanuginosa.

Perennials for a Rough Stone Wall.

I have 120ft. of stone wall 5ft. high and 2ft. thick, the sides dressed and pointed, but the top of large rough stones with many pockets. Kindly give me a list of plants suitable for this wall top. Free-flowering perennials of a hanging habit are what I have in mind, but would try any suitable subjects you recommend for this position.—J. H. W., Corstorphine.

Small rock plants as well as fairly large trailing perennials will flourish in a rough stone wall if the pockets of soil are of reasonable size. Antirrhinums, wallflowers and Cheiranthus Allionii (the Siberian wallflower) would all succeed. Other suitable plants are: Aubrietias in variety; armeria in variety; Cerastium tomentosum; Dianthus in variety; Sedum rupestre, S. spathulifolium; Alyssum saxatile; Arenaria montana; Acantholimon glumaceum; Gypsophila repens; Iberis sempervirens; Saponaria ocymoides; Thymus in variety; Phlox subulata; Lithospermum prostratum Heavenly Blue; Saxifraga hypnoides.

NOTES AND COMMENTS

The Day of the Hardy Plant.

LECTURING recently before the members of the Glasgow and West of Scotland Horticultural Society, Mr. John Highgate, Dankeith, Kilmarnock, submitted a number of practical hints on the culture of herbaceous plants which will be found helpful to amateur gardeners.

There is no doubt, he said, that this is the day of the hardy plant. The infinite variety of form and colour was more appreciated than ever before and for adaptability there is no other class of plants that can compare with them. Large numbers are perfectly at home in sunny positions, others flower equally well in shade, while another class will revel in damp and moist situations. A carefully thought out and judiciously planted border with the colours arranged to harmonise will produce a picture that will give pleasure for many years and that with the least expense of all styles of gardening.

Regarding the very debatable point whether we should plant in autumn or spring, the lecturer suggested that the deciding point should be the nature of the soil and climate. More plants were lost through dampness than anything else and in a cold, adhesive soil he would defer planting till the spring, although disastrous effects resulting from a long spell of drought in that season could not be overlooked.

Reviewing the plants found in a representative collection, Mr. Highgate began with the stately delphinium, which was recommended for autumn planting. The dying off of plants during winter and early spring was due to slugs, which made a practice of eating out the dormant shoots and as a remedy he suggested that the crowns should be covered with 2ins. of finely sifted coal ashes worked well down in the hollow parts.

As regards the Caucasian scabious, it is useless to plant it in soil that is inclined to be stiff and adhesive. Half of our troubles with many choice hardy plants could be attributed to cold, wet soils and in the case of the scabious it would only flourish in a well drained light soil with full exposure to the sun.

The herbaceous phlox should not be planted in close proximity to trees or shrubs, because they do not thrive among a collection of stronger growing plants. In the earlier stages of growth thin out all weak and superfluous shoots and apply a liberal top-dressing of manure in summer so that the plants may not suffer from drought.

Montbretias require a little more attention than is usually bestowed on them. They like a light sandy soil that has been deeply worked with well rotted manure and leaf soil. Where most growers fail, particularly in cold and wet districts, is by leaving them in the ground through the winter. It is better to lift them towards the end of October and store them in boxes among sand, where they will be free from frost. In mid-February divide them up, retaining only the strongest bulbs, which should be put into ordinary cutting boxes and started gently into growth.

Herbaceous peonies are not fastidious as to soil and are perfectly hardy. As they send down their thong-like roots to a depth of 3ft. or more, the ground should be trenched to that depth and peonies being gross feeders, the soil must be heavily manured. They resent frequent disturbance, but when this becomes necessary the work should be performed not later than September.

Michaelmas daisies do not receive the attention they deserve. How often does one see large clumps about a yard through with poor miserable flowers, yet when regularly replanted and carefully staked, they form a fascinating sight. Replant almost every year, selecting only a strong shoot from the outside of the group and if the soil is in anything like good heart they will give splendid results.

Gaillardias growing in cold, wet soils will be all the better for some protection in winter, as they are inclined to damp off under these conditions. Eryngiums succeed best in the open and the torch lilies should have their own leaves bound round them as a protection in winter. Unlike most plants the more the blooms of heleniums are cut the longer they seem to flower. Helianthus should not be planted extensively among other plants as they have a nasty habit of spreading their tubers in all directions under ground and so become a nuisance.

This Week's Work

Sow seeds of Brussels sprouts thinly on a mild hot-bed, and cauliflowers on a warm border.

Sow a few rows of onions, spinach, and turnips outside.

Prepare seed beds for hardy annuals.

Start tubers of bedding begonias in a warm greenhouse.

Prick out seedlings of annuals and vegetables raised in the greenhouse.

Finish planting any herbaceous perennials and shrubs.

Prepare coverings for protecting fruit blossom from frost.

Plant some shallots.

Sow some tomatoes in pans of light soil in a greenhouse.

The New Alpine House at Wisley.

THOSE who are interested in alpine plants, and the number at the present time is numerous and seems to be increasing yearly, would be well repaid by visiting the new alpine house at the Royal Horticultural Society's Gardens at Wisley. This house, which has been recently erected on high ground near the Meterological Station, is from its position and structure admirably adapted for the cultivation of alpine plants. The house is now furnished with pots and pans of well grown plants of healthy and vigorous appearance. Among the numerous forms of Saxifraga Burseriana now in flower probably one of the most fascinating is the variety known as S. Burseriana crenata, with its cushion-like habit of growth and pure white flowers which are beautifully crenulated. It is a delightful subject for early flowering. S. B. Gloria, S. B. tridentina, S. B. major and S. B. Kestonensis are all represented by well grown plants. Others of the rockfoil family include many pans of S. lilacina from the Himalayas, which is just coming into flower. Among hybrids mention ought to be made of S. Riverslea, S. Lady B. Stanley, S. Ada and S. Perle Rose. S. Tranzi is a pretty plant just opening its yellow flowers. S. Kellereri is one of the best of the early-flowering hybrids, and is represented by a well grown pan. S. Sundermanii, a charming cross between marginata and Burseriana, is very freely flowered. That exquisite species S. Rocheliana with its dense rosettes of silvery leaves is also a charming plant for pans for early flower.

Beside the saxifrages there are many other plants of interest to the alpine enthusiast. Morisia hypogæa is one of the most desirable of alpine plants with its bright yellow flowers rising very little above the tufted foliage and should be in every alpine house; incidentally, it may be mentioned slugs are very fond of this when planted in the open. The charming Primula Winteri is represented by a few pots, but this is seen to better advantage in a nook in the rock garden facing north, where established plants are flowering most profusely. From the foregoing it will be seen that visitors to the gardens will find the early alpines a source of interest at present.

The result of our Crossword Puzzle competition will be found on page xvii.

THE PRINCIPLES OF JUDICIOUS PLANNING

MOST garden lovers, I venture to say, are well acquainted with Miss Gertrude Jekyll as an influential writer on horticultural subjects. Has she not truly said: "Gardens may either be fashioned into a dream of beauty, a place of perfect rest and refreshment of mind and body; a series of soul-satisfying pictures, a treasure of well set jewels; or they may be so misused that everything is jarring and displeasing: to learn how to perceive the difference, is to apprehend gardening as a fine art."

How often do people walk round their garden and realise that something is wrong, in spite of all their care and attention: somehow they do not get the effect they want. Very often one hears the remark that "We must do something to get some colour and shade into it," and then forthwith proceed to make certain alterations in order to achieve their aim. Flower beds are made here and there, trees planted, lawns laid, etc., only to find in a year or two that the trees are in the wrong place, that the flower beds have to be altered, that the tennis court would have been better elsewhere. Then begins the heart-rending business of uprooting trees, moving the orchard, transplanting the flower beds, and re-laying the tennis lawn: and all, perhaps, to no purpose.

Several years have probably been wasted, a great deal of labour and money expended, and, instead of a beautiful garden growing up before our eyes, confusion alone reigns.

Haphazard design and planting may not always be obvious at once; but it will be there. And there will always be a sense of dissatisfaction that something is wrong, which will just spoil the whole effect.

The majority of amateur gardeners have, at some time, to make a new garden, and really, it is a task that gives the enthusiast endless pleasure when the job is undertaken in a systematic and prudent way. The best method to follow, undoubtedly, is carefully to plan the whole thing out on paper first, to a suitable scale. The plot of land in question must first be surveyed, all measurements being taken, with notes on any irregularities that may occur out of the square, and not forgetting to indicate clearly the north point, which is most essential.

Any undulating portions with approximate variations, should always be stated. This having been done, it is quite an interesting job for a winter's evening to plan out the garden of your dreams in the comfort of your home.

Having decided on your scheme in your mind's eye, proceed to reproduce that vision in black and white. A piece of three-ply wood about the size of your dining-table is quite suitable for the purpose, as the lines can be first chalked on as a preliminary measure; any lines that are not required can easily be wiped off with a damp cloth. When, however, the scheme is considered correct, proceed to rule in the lines with a black pencil, only more accurately this time. It must be remembered that the scale should be arranged from the measurements taken on the site, to suit the confined space of your improvised drawing board. It does not matter whether it is an ordinary villa plot or a site several acres in extent; by a little calculation one can soon make a scale rule suited to the purpose.

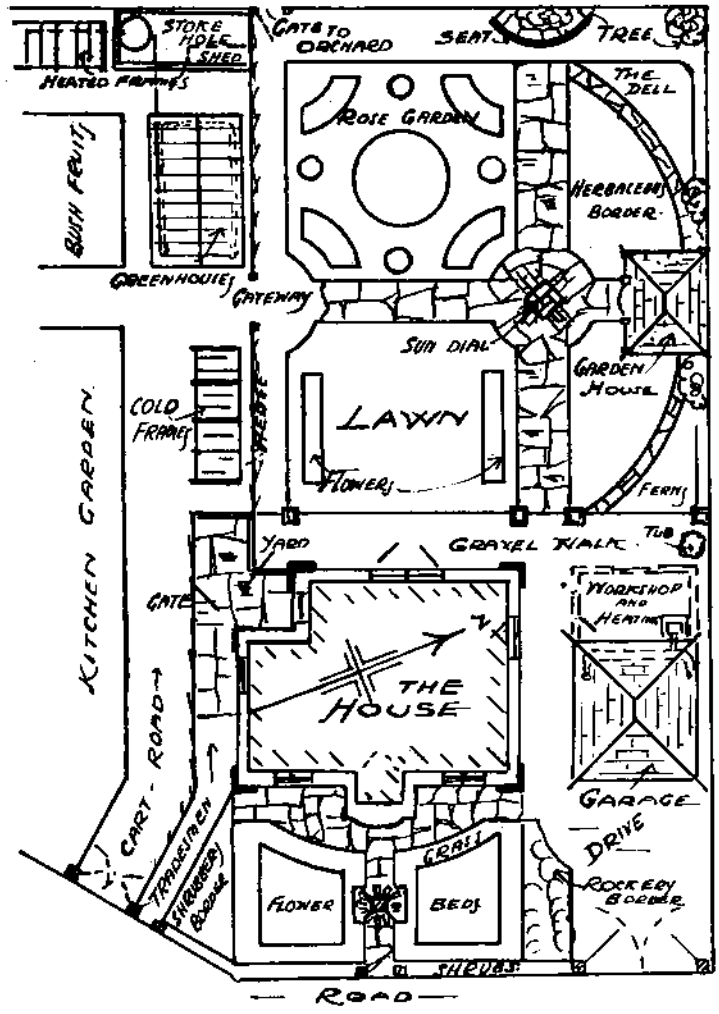
Some may prefer to cut strips of paper, to represent the various paths, lawns, borders, and so forth, and to place them in different positions on the lay-out, to get the effect of them collectively.

If the scheme is a large one it may take years to develop properly, but this does not matter; proceed to plan it as though the whole thing was to be completed in a season. Once the plan is made, whatever part is commenced first can be done thoroughly and permanently, and as, year by year, another section is completed, you have the satisfaction of knowing that you are adding to the beauty of the whole. Nothing, in my opinion, is more demoralising than to find, after a lot of hard work and expense, that we must start altering something that is in the wrong place.

There is often a tendency among amateurs to try to arrange the plan of construction as the work proceeds; but this procedure generally spells disaster and dissatisfaction.

The scheme under consideration in the accompanying plan is on an irregular site, being at the bend of a road; this, naturally, gives great scope, and many original features have been suggested therein.

Immediately opposite the front entrance of the house, a paved stone walk forms an imposing approach; ornamental flower beds are arranged on either side of the central path, with a grass verge 18ins. wide bordering them. On one side of the flower beds a triangular shrubbery border is arranged in the corner, which can be made both useful and ornamental, if a little care is exercised when planting. On the opposite side, a rockery border is constructed and should give much variety to the front drive. A garage is indicated on the plan, with a lean-to workshop or power-house suggested at the rear portion. These buildings, however, may be later additions, but should be clearly specified on the plan of the garden in order to reserve these sites; the same applies to other features in the garden that require a special location or aspect.



The kitchen garden is divided from the tradesmen's entrance by a macrocarpa or other dense hedge; a cart track leading from the road serves the utility portions of the garden, and it is quite worth the space it occupies from a labour-saving point of view.

A spacious rose garden is allotted a very prominent and sunny position, also a range of pit lights, greenhouse and cold frames. A combined stoke-hole and potting-shed is in close proximity to the scene of activities. Another 6ft. hedge separates the kitchen garden from the pleasure garden, and an archway formed in the shrubs serves as an entrance from the flagged walk which separates the lawn from the rosary.

A broad herbaceous border occupies a good space, in which is recessed a garden house. Narrow curved paths of stone bisect these borders, the smaller portions being reserved for shade-loving plants and ferns respectively. The broad walk is composed of brick and stone, with an ornament as a central feature. Large trees are indicated on the plan, as it is suggested that they shall remain standing in this case. A good deal of discretion, however, should be used in the arrangement of beds and borders in conjunction with big trees, for reasons which are obvious.

Any garden buildings or important features that are anticipated for future innovations should be clearly marked "proposed" on the plan, so that these sites can be reserved, but used temporarily as seed beds or nursery ground, etc., as circumstances arise.

Land drains, sump holes and all accessories that form the component parts of the general lay-out should be defined on the drawing, so that when the actual landscape operations are in full swing, no valuable time need be lost discussing various points; the book will be open to all concerned.

Good proportions are a predominating factor in the planning of most things, especially gardens, and simplicity of design combined with judicious planting adds greatly to the amenities of the garden beautiful.

The house may be excellently built, but if the garden is wrong the house will look wrong also, and the result will be just as bad as a beautiful picture badly framed.

PEONIES FOR THE JUNE BORDER

IT would not be easy to point to a hardy herbaceous plant which has received more attention at the hands of specialists than the peony, or one which has made such rapid advances in the estimation of garden lovers. One of the oldest of plants, it was represented for long by one or two sorts—red and white—being found mostly in country gardens. The very beautiful array of both double and single hybrids we have to-day in such glorious colourings, we owe to the painstaking, persistent work of the specialist, and in this connection we couple the name of the firm of Kelway of Langport, who were among the first in this country to appraise their worth, and to whom we are indebted for many choice varieties. I remember in earlier days that it was looked upon as a great mistake to attempt to remove or interfere with a peony, once it had become established, because of an idea then prevalent, that it took years for plants to get over the disturbance. It was only part of a truth, however, as, although when once planted it is not advisable to remove them more than is absolutely necessary, it has been proved, that given proper soil and right quarters, these plants get over their shift much more quickly than most people imagine. While it is an advantage to do any planting in autumn, it may be said that March is not too late, providing the ground has been prepared.

ONE OF THE CHOICE MODERN SINGLE VARIETIES.

Soil.

For herbaceous peonies this should be rich and deep, and the site they are to occupy ought to be trenched 2ft. deep, and good rotted stable manure, leaf mould and loam well incorporated. If the existing ground is known to be poor, then the soil should be removed, and the fresh, as suggested, substituted. They are plants which will thrive in sun, or partial shade, and in the latter position the display of bloom is of longer duration. For their advantage, it is always best to apply a good mulch of old manure on the surface some weeks before the blooming period; this tends to keep the roots cool, and is of great value supposing the season be dry.

Value of Flowers for Cutting.

Both single and double sorts include many that are possessed of charming tints, and are delightful for cutting for vase decoration. Some commence to flower in May, while others are in full beauty during June and early July, being enhanced by a wealth of foliage in bronzy green and metallic colourings setting off the superb flowers to perfection. The blossoms should be cut before they are fully developed.

Fragrance.

Those planting peonies for the first time are usually drawn to them by the exquisite beauty of the flowers, and sometimes overlook that they have another attribute, *viz.*, that of perfume. It is a subtle fragrance surely, embracing the sweetness of some roses, and the winsomeness of a violet—not easy to describe, yet there all the same.

Watering.

Peonies will take copious supplies of water and in the case of recently planted clumps, it is important that they should not be permitted to suffer from dryness. Established clumps will also benefit by applications of liquid manure once or twice a week when approaching the bud stage.

General Remarks.

It ought not to be overlooked that these hardy flowering plants, are really *very* hardy, severest winters affecting them but little; that they make a garden very gay before the bulk of summer flowers appear; that they will do well in partly shaded positions in a garden, and in the second year after planting some will begin to bloom and add grace and beauty as the years go on. So purchase some of these beautiful perennials and plant them in your garden during the next few weeks.

Varieties.

It is a task to select from so large a number of present day sorts, those for planting, when so many are lovely. No blossom is more gorgeous in the garden in late spring and the first flush of summer than the peony. No plant, once established, is easier to grow.

From the many superb sorts to-day, the after-mentioned are but a few, and there are others equally beautiful.

Singles.

The Queen, white and blush.
Lord Morley, crimson purple.
Conquest, bright rose.
Duchess of Sutherland, flesh.
Adam Bede, crimson maroon.
Pride of Langport, peach pink.
Bridesmaid, pure white.

Doubles.

Agnes Mary Kelway, light rose and yellow.
Santoin, rose self.
James Kelway, white.
Birket Foster, crimson scarlet.
Langport Triumph, lilac and white.
Duke of Devonshire, deep rose pink.
Lady Romily, flesh.

W. LINDERS LEA.

PEONIES IN FULL FLOWER IN THE EARLY SUMMER BORDER.

SOME SCENTED HARDY ANNUALS

MOST familiar among the hardy annuals—they are not very many—that have perfume as an addition to their attractions is mignonette. Of this, many people are firmly convinced that the common sort is the sweetest; but, as a matter of fact, although some of the so-called "improved" varieties introduced some twenty or thirty year ago were rather lacking in scent, the newer ones, such as Sutton's Giant and Barr's Covent Garden Favourite, are to the full as rich in odour as the old type. The Giant Mignonette is 18ins. high, and is best grown

THE ANNUAL PINK IS ONE OF THE MOST FRAGRANT OF HARDY ANNUALS.

in a bed by itself, or in large patches in a broad border; most of the others are about 1ft. in height, but the red-flowered variety, M. Victoria perfecta, is only 8ins. tall and makes a charming edging or carpeting. Other scented annuals sufficiently dwarf to be used for either of the purposes named are sweet alyssum, all brands of which have a delicate honey scent markedly perceptible under a hot sun; the blue woodruff, Asperula azurea setosa, the perfume of which is more elusive than that of the white perennial variety but is very pleasant; and—less well known than the two just mentioned—Eucharidium Brewerii, which has very pretty rose-coloured flowers. Like all the tribe of pinks, Dianthus Heddewigii is sweet-smelling, but the strength of the perfume is more noticeable in some varieties than others.

The scent of Centaurea moschata, better known as Sweet Sultan, is to some people objectionable, heavy and cloying, but at a little distance whiffs of it are undoubtedly delicious. The seed is generally sown in mixture, but that of the different colours—white, mauve, purple and yellow—can be had separately and usually comes fairly true. Sweet Sultan, especially the giant strain, which is from 1½ft. to 2ft. high, is excellent for cutting, the flowers lasting a long time in water. The best results are got from autumn sowing in the open, preferably in soil that has a good deal of lime in it. The sweet scabious (purpurea), otherwise Mournful Widow, is now obtainable in colours that are far from being mournful—scarlet, blue and purple to wit, as well as white. It is really a biennial, but it is wisest to treat it as a half-hardy annual, raising it in slight heat and planting out the seedlings in May.

There are three plants which should always be grown near the house so that their scent may be fully enjoyed through the open windows on summer evenings. The first is Nicotiana affinis, a gawky grower, but the delightful perfume of its snowy flowers when they open at dusk makes ample amends for this defect; the second is Œnothera odorata, a yellow-flowered evening primrose about 3ft. in height, which is a hardy annual, not a biennial or perennial as are most of its relations; and the third the night-scented stock, Matthiola bicornis (otherwise tristis).

The orange-coloured flowers of that pretty cousin of the wallflowers, Erysimum Petroffskianum, are agreeably scented. It is about 15ins. in height, and it thrives best in a dry, fairly warm soil, as does Schizapetalon Walkeri, the fringed white blossoms of which smell strongly of almonds, especially after rain. It is not quite so tall as the erysimum, and should be sown where it is to bloom. All the members of the stock family are more or less scented, but the only one which can be regarded as an annual is the ten-week type, and that is only half-hardy. R. E. H.

Sweetly Scented Sweet Peas.

OF course, one cannot say with absolute certainty, but most probably sweet peas owe the first half of their name to their scent, one of the most charming qualities a flower may possess. One is often asked the question, "Do modern sweet peas possess the perfume of the old-time favourites?" To some flower lovers fragrance is an asset greater than either colour or form, while many consider it at least of equal importance.

Taking an average of all sweet pea varieties, it is a fact that the newer varieties of the Spencer or waved type are not so *strongly* scented as the old grandiflora or plain standard kinds, such as Lady Grizel Hamilton, Black Knight, King Edward VII, etc. Some would prefer the light and perhaps somewhat elusive fragrance of the present-day varieties.

There are, however, quite a number of varieties of the better class sweet peas which retain nearly, if not quite, the volume of perfume usually associated with the grandifloras. Curiously enough in similar colours, the degree of fragrance is similar, that is, the scent of all lavender varieties is of about the same strength. This peculiarity allows us to divide or classify the different colour classes into at least three sections, which for convenience I will term the highly fragrant section, the fairly fragrant section and the non-fragrant section. In each fragrant section, after naming the colour class, I will mention one or more first-class varieties of that colour.

HIGHLY FRAGRANT COLOURS.

Purples.—Royal Purple and Purple Perfection.

Maroon.—Warrior and The Sultan.

Mauve.—King Mauve and Mauve Beauty.

Lavender.—Powerscourt, Wistaria, Mermaid, Austin Frederick Improved, Wembley and R. F. Felton.

Blue.—(Light) Blue Butterfly. (Medium), Heavenly Blue, Mrs. Tom Jones and Bluebird. (Dark) Commander Godsal and Jack Cornwell V.C.

Crimson.—Sybil Henshaw, Charity and Unwin's Crimson.

Rose.—Sunset (Bolton's), Empire and Private Jack Smellie.

Carmine.—Renown and Mascott's Ingman.

Pink.—Only the pinks without orange or salmon in their composition, such as Hebe or Miss Philadelphia, would I classify in this section, the remainder are only "fairly fragrant."

FAIRLY FRAGRANT COLOURS.

This section is by far the largest.

White.—Only dark seeded varieties such as Constance Hinton and Giant White are fairly fragrant.

Blush.—As a rule the deeper the tone of colour the stronger its perfume. Elegance, Valentine, Felicity and Dainty Maid.

Pink.—Supreme, Hawlmark Pink, Hawlmark Salmon Pink, Tom Sykes, Mrs. Chas. W. J. Unwin and Pink Perfection.

Cream Pink.—(Light) Venus, Cecily and Mrs. Arnold Hitchcock. (Deep) Picture. (Salmon) W. J. Unwin, Miss California and Magnet.

Flushed (both on white and cream grounds).—Mrs. Horace Knight, Carmelita, Del Monte, Queen of Roumania and Britannia.

Picotee.—(On cream) Jean Ireland and Improved Jean Ireland. (On white) Youth and Annie Ireland.

Bicolour.—Bonfire and Mrs. Cuthbertson.

Lilac.—Lilac Queen.

Stripes.—Birdbrook, Senator, Spencer Twinkles and Lady Gay.

Cream and Ivory (all black seeded.)—Ivory Picture, Daffodil and Leslie Rundle.

Orange Pink.—Crusader, George Shawyer and Royal Pink.

Orange Cerise.—Grenadier, 2 L O, Royal Scot and Pimpernel.

Orange Scarlet.—Mammoth and May Unwin.

Orange.—Wizard, Royal Sovereign and Guinea Gold.

Cerise.—Charming, Centaur and Coralline.

Salmon.—Gold Crest and Melba.

Scent in sweet peas is most pronounced during warm weather and greater in the evening than in the early morning. As far as I have observed, culture makes little or no difference, exhibition or cordon grown flowers seem to possess as much perfume as those grown naturally.—C. H. A. S.

THE SEA HOLLY.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

THE EVENING PRIMROSE.

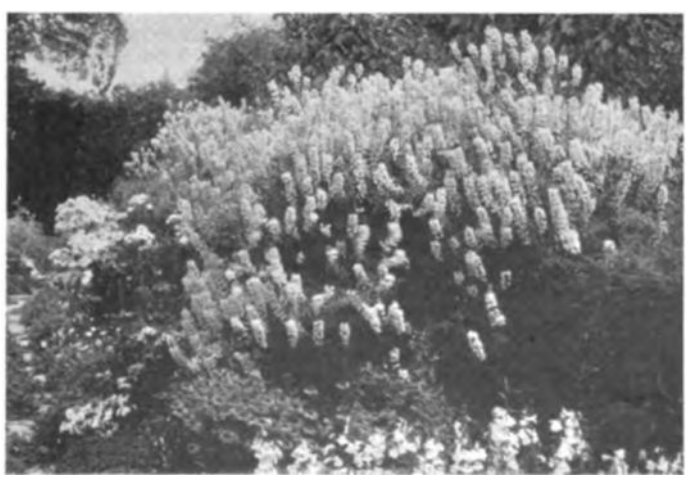
Eryngium (Sea Holly). THESE are among the hardiest of herbaceous plants for border planting and valued owing to their thistle-like flowers or bracts, which are of metallic colourings, some steely blue, that are at their best from July to September, and last for a considerable time after they have been cut. On this account they are serviceable along with other "everlastings" for winter decoration. The requirements of eryngiums are few and may be summed up in good ordinary soil, which should be well drained, and a sunny position. Heavy wet soils are fatal to the plants. Favourites as back row plants and growing 2ft. to 3ft. in height, they ought to be given sufficient room clear of other things. The stems are as beautiful as the bracts, having an attractive, glistening appearance. Eryngiums can be increased by root cuttings taken in spring and planted in a cold frame or pans of light, sandy soil, or from seeds sown in spring, but as the plant has a propensity for self sowing, the question of sowing seeds is not often considered.

Galega (Goat's Rue). THE galega is a herbaceous hardy perennial, often met with in town and suburban gardens, bearing freely numerous pea-shaped flowers in blue and lavender and white, from amid a wealth of fine foliage. It is a plant which invariably does well in the hands of an amateur and will thrive in any ordinary garden soil helped with manure occasionally. It loves a sunny position and grows into a very shapely plant in a border—suitable for a back row. It ranges from 3ft. to 4ft. in height and should be given that room between its neighbours. Propagation is by division of roots in the autumn, or spring; from cuttings of the young shoots taken when 3ins. or 4ins. long in July or August, and inserted around pots of sandy soil placed in a cold frame, or from seed sown out of doors in light soil in May. The galega grows rapidly and should be split up every two or three years.

Godetia. AN annual which has come to be looked upon as almost indispensable in a number of gardens in connection with summer arrangements. They have a wide range of colour, and yield both double and single flowers; some are dwarf, about 9ins. in height, and are being appreciated more every year for bedding purposes. Others are from 2ft. to 3ft. in height, and are good for planting on the front of the shrubbery border or at the back of mixed borders. Seed may be sown in heat in March in pans of light soil, but this is not absolutely necessary unless plants are wanted to bloom early, as sown in a cold frame in April, or even on a warm well drained border towards the end of the month, one may have a show of the blossoms from July and onwards for many weeks.

Œnothera (Evening Primrose). THE œnotheras are represented by perennial, biennial and annual forms, and though they are commonly considered as evening bloomers, some of them yield their flowers by day. Among the perennial sorts there are both white and yellow, some of quite a dwarf habit (6ins.), others rising to 2ft., useful for the rock garden and borders. A moderately rich soil, inclined to be sandy and well drained suits them. In cold, heavy soils they often die off in winter. March is planting time. Seed sowing should take place in April in the open ground, or cuttings can be taken in August or September, planted in pots of sandy loam and wintered in a cold frame. Annual sorts should be sown out of doors in April in a border having a warm and sunny position. Fragrance, rather delicate, is one of the characteristics of the evening primrose.

Aubrietia. A VERY great favourite for the rock garden for planting in niches on stone walls or for use as an edging plant is the aubrietia. It is found everywhere, as it accommodates itself to most soils so long as they are well drained. It does not like a heavy soil, but thrives best in a medium or sandy one. Few rock plants in their flowering season, which is May and June, bring a greater wealth of blossoms or are so vivid in colour. Growing only about 3ins. or 4ins. in height, they are useful for filling crevices between garden paths. Propagation is of the simplest, either from seed, which can be sown in the open ground or in pans in sandy soil in April or May; from cuttings taken near a joint with a particle of the old stem and dibbled firmly in the ground; or by division of plants. Both the latter operations can take place in July. It is important that until roots have formed shade should be afforded. In clothing a stone wall it is best to adopt sowing rather than attempt cuttings, and if a little of the compost is made ready and a few of the seeds scattered about it and then forced into the crevices, more success follows this plan than to attempt cuttings, which sometimes get dried up through lack of moisture in elevated positions. If the soil is very dry, it will be an advantage to damp it before pressing it in the wall spaces. Started on these lines, little difficulty is experienced in clothing a wall with aubrietia.



THE GOAT'S RUE (GALEGA) IS A FINE HARDY, BUSHY AND FLORIFEROUS PERENNIAL FOR BORDER PLANTING.

THE BUSY MAN'S PAGE

Six Good Shrubs for Spring Planting.

Berberis Darwinii.—A small evergreen which bears brilliant orange flowers in April and plum-coloured fruits in the autumn.

Buddleia variabilis Veitchiana.—A fine tall-growing shrub with greyish foliage and handsome spikes of purple-violet flowers borne during the summer.

Ceanothus thyrsiflorus.—A blue-flowered evergreen shrub for the house wall. It flowers in May and June.

Deutzia scabra.—A deciduous shrub for the small garden. It bears clusters of pure white flowers in May.

Kerria japonica fl. pl.—This shrub bears masses of double orange-yellow flowers. It is suitable for planting against a north wall.

Philadelphus Lemoinei.—A neat-growing mock orange of 5ft. in height which covers itself with sweetly scented white blossoms.

Daisies on the Lawn.

IT is generally accepted that an abundance of daisies on the lawn is a sign of barrenness, of a lack of plant food and of a certain sourness demanding treatment. Nothing will improve lawns in a bad state through the above better than a dressing of lawn fertiliser, a little bone meal or a feeding mulch of sifted manure, leaf-mould or rich soil. At this time of the year top-dressing of artificials will prove best, for various reasons; apply 3oz. of lawn fertiliser per yard, selecting a good artificial brand, bone meal or guano, let the grass grow rather long and then mow for the first time with a scythe. Daisies in isolated patches, however, are a real pest of all lawns; spudding out is often a tedious job and not always effective, but light, repeated dressings of lawn sand or suplhate of ammonia or copperas (sulphate of iron) actually works wonders. Apply such on *dry* evenings; by the morning the dew will have dissolved much and the daisies will be blackened. Repeat a little later, when the effect of the chemical is disappearing (through lapse of time or rain) and the weeds will gradually disappear; 4lb. sulphate of ammonia, 1lb. copperas (both in fine powder) and 14lb. to 6lb. sand makes a very fine "daisy-destroy." which, while doing that good work, also feeds the grass. It must not be overlooked that the removal of daisies may leave bare patches; if so, tear the surface loose with a rake, scatter seed and cover with a little sifted soil, then roll. Should a starved lawn not be in use for a time, it may still be possible to scatter some horse litter manure over the daisy patches; this must be stirred with a broom weekly and the residue completely removed at the end of a month. Such treatment leads to the formation of a fine, springy "mat," and materially reduces the incidence of the pest.

If Your Ground is Very Light.

WHERE ground is of a very light, porous nature, on which crops suffer badly during dry weather, it is as well to defer the digging until after the turn of the year. Then something must be done to bring the ground into better condition, so that it will be firmer and more compact of texture and thus retain the moisture more completely. In dealing with very light ground, many gardeners concentrate too much on the upper spit. As a matter of fact this is not the one which calls for the most attention in these cases; actually the subsoil, or second spit, must be dealt with, for, if this remains extremely porous, the treatment of the top layer of the ground will not be of much avail. The top spit should be turned on one side and all energies directed towards making the subsoil firm and more impervious to water.

A very good way of dealing with very light ground is on the following lines. Dig a trench from 6ins. to 10ins. deep, according to whether shallow or deep rooting plants are to be grown. Two feet is a suitable width, and the soil which is removed should be wheeled to the other end of the border and kept for filling up the last trench. In the trench thus exposed spread a thick layer of moist cow or pig manure, soft vegetable refuse, or anything that will form a damp mass for binding the loose soil together. About a barrow load to every 6yds. or 8yds. of trench should be allowed. Dig in this material well, not merely burying it, but working it uniformly into the subsoil and finally trampling it down to consolidate the mass. Open up another trench similar to and alongside the first, putting the soil on the top of the subsoil already treated in the first trench. Repeat the operation described with the second trench and continue the process until the whole of the land has been treated.

A week or two before planting, the top spit of ground may be lightly forked over and some manure added. Good short dung can be used with good effect, or one or other of the artificial fertilisers at the rate of 2oz. to 4oz. per square yard might be employed. When dry weather comes the roots of the plants pass downwards to the more retentive subsoil, where they find the moisture that they require.

THE BLUE-FLOWERED "CALIFORNIAN LILAC," CEANOTHUS THYRSIFLORUS.

House Plants.

GREEN plants, such as ferns and foliage, respond at once to a dose of castor oil applied to the roots; a dessertspoonful for a good-sized plant. Sardine oil also is excellent, containing phosphates. Do not use the cheap sort, as that often has much salt.

Keep your bulbs watered after flowering, till the leaves dry off naturally. They store food for next year in their leaves. Then dry the bulbs and replant in September.

In winter once a week may be all the watering necessary for house plants, but in warm weather and when in flower, twice a day may not be too much. Knock the pot with the knuckle; if it sounds hollow, give water.

If the leaves turn yellow, too much water has been given, or there is a wireworm at the root.

When repotting, use only the next size in pots, and plant firmly at roots and sides.

If you put plants out of doors to water, be careful that they are sheltered; pots are porous (if clean!) and the roots easily get chilled. Put them on a board or grubs and worms will creep into the pot.

All About Pots.

WHERE flower-pots are made, a certain amount of clay is called a "cast," and the number of pots which can be made from this "cast" is the number by which the size of the pot is known. Thus 12's implies that the cast has been made into twelve pots. Generally speaking, a flower-pot measures the same in depth as in diameter across the top. The common sizes are as follows:

"Thimbles" are 2ins. in diameter across the top and 2ins. deep.
"Thumbs" (72's) are 2½ins.
Sixties (60's) are 3ins.
Forty-eights (48's) are 4½ins.
Thirty-twos (32's) are 6ins.
Twenty-fours (24's) are 8½ins.
Sixteens (16's) are 9½ins.
Twelves (12's) are 11ins.
Eights (8's) are 12ins.
Sixes (6's) are 13ins.
Fours (4's) are 15ins.
Twos (2's) are 18ins.

Bigger sizes of pots are made, and here the depth is usually a little less than the top diameter. The idea of making a pot wider at the top than at the bottom is in order to facilitate the removal of the specimen with a ball of earth round its roots. In addition, the wide top part ensures that the largest amount of soil will be where the roots are most plentiful. Glazed pots are not really so good as those of ordinary make. The only advantage is that in the non-porous pot the soil keeps moist for a longer period and so watering need not be so frequent. As against this there is a danger that the soil in such pots will become sour owing to the way in which the water tends to stagnate.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Lilies in Boxes and Pots.

I HAVE seen a pretty red lily, Lilium rubrum, flowering freely in one of London's inner boroughs, and it is frequently grown by those who have no gardens other than boxes and tubs. Nearly all the lilies will give good results grown in tubs, or large pots. The varieties usually grown in this way are: auratum (gold), speciosum (pink), longiflorum (white), and regale (golden white).

The secret of successful lily culture is good drainage. They cannot be grown in soil that is waterlogged, and borders to receive them must therefore be deeply dug. If pots are used, they should be deep, and should be well supplied at the bottom with drainage crocks, over which a potting compost of loam, flaky leaf soil and sand mixed in equal parts should be used. Sharp sand is particularly desirable, and a little of this just under the bulb when it is planted will be appreciated. The pots or tubs should remain in a cool place while the roots are forming.

Border Lilies.

A SIMILAR soil to that advised for pots should be used for lilies in the border. It should be well trodden, the bulbs then placed in position, a sprinkling of clean sand round them, and more soil filled in to the level of the rest of the border. The bulbs are best planted a foot apart, in groups of six or seven, the site being immediately marked with a stick to prevent disturbance. Most lilies enjoy shade at the roots, and are therefore quite suitable for planting among dwarf plants, such as violas, alyssum, etc. Although hardy, lilies benefit from a sifting of coal ashes round the stems in winter. This keeps them both drier and warmer and also prevents slugs from attacking the young shoots in spring. Decayed leaves put round the plants during dry weather make the soil conditions equal to those in the natural state. This is a point worth emphasis. It is always safe for those in doubt on the culture of any plant to try to reproduce the conditions which obtain in districts where it grows in a wild state. It is usually when we fail to do this that the plants do not thrive.

For a very shady garden, the Turk's Cap lily should be selected, but for a sunny garden the following varieties will give a wide range of colours: croceum (orange lily, 3ft.), tigrinum (tiger lily, 3ft.), candidum (Madonna lily, 3ft), auratum (Japanese golden rayed lily, 5ft.), speciosum rubrum (red Japanese lily, 3ft.), testaceum (Nankeen lily, 5ft.).

Starting Dahlias.

ONE of the best plants for a town garden is the dahlia, and amateurs who have kept their tubers from last year should now take them out of store and clean them. It is best to start dahlias into growth before planting, and this allows for increase of the stock of favourites. Use a wooden box, about 6ins. deep. Cover the bottom with a layer of decayed leaves 1in. thick. Stand the tubers on to this, taking care, if several sorts are together in the same box, that they are labelled. Then cover them 1in. deep with sifted leaf mould, water and protect from frost. This can be done by standing the box in a frame on a mild hot-bed or in a warm greenhouse. When the young shoots begin to grow, admit air on all favourable occasions. The shoots, when about 3ins. high, can be made into cuttings. The cut should be made horizontally, immediately below a joint. The cuttings root readily in a sandy soil if covered with a piece of glass, or a bell jar. These should be grown on carefully, with not too much forcing, and they will form sturdy plants to put out in the open border in May.

Dahlias can also be increased by dividing the tubers, taking care to retain a piece of tuber with each shoot. These can be grown in pots in a sunny window until they are ready for planting out. The worst enemy of the tubers is the slug, and these are best treated by dressing the soil occasionally with a mixture of soot and lime.

Planting and Pruning Fruit Trees.

IN planting fruit trees, use the previous soil mark as the guide of the depth at which to plant. Spread out the roots evenly, cutting away bruised and damaged portions. Fill in a little light soil over the fibrous roots, and tread it fairly firm before filling in the remainder of the soil. Do not forget that newly planted trees and shrubs *must be staked.* Otherwise they become loosened by winds. If plants arrive during frost, cover the roots with moist soil, and leave them until the frost breaks. Just before growth commences, shorten the side shoots about one half their length, *cutting to an outside bud.* Never prune fruit trees without looking for an outside bud, or the result will be shoots which cross each other and keep out the light and air from the centre of the plant.

To pick good fruit from small trees and bushes in the town garden is quite a possibility, as will be seen from the illustration of apples growing at the back of a mixed flower border. In a small garden, the selection of kinds should be made very carefully. Apples are useful, but care should be taken to plant either self-fertile varieties or those which flower at the same time and will pollinate each other, say James Grieve for dessert and Bramley's Seedling for cooking. Loganberries, black currants, raspberries and gooseberries are all profitable crops in the small garden.

Intensive Cropping.

THE French gardener has practised intensive cropping for many years. He commences this work in the springtime, and arranges for three crops. From the frames cabbage lettuce are planted out, 10ins. apart. At the end of March, cauliflowers are set between them.

As the lettuce is removed, spinach or radishes can take its place. The cauliflowers should be ready at the end of June and late carrots or celery can follow these. Such rotations can be made in endless variety and I will give a few suggestions of vegetables which can be cropped in the order given on one piece of ground, in a year.

1.—Second early potatoes (sprouted), cabbage, coleworts, lettuce, broad beans.

APPLE TREES IN A TOWN GARDEN.
The varieties which are growing are Stirling Castle and Lane's Prince Albert.

2.—Early peas, second early potatoes, Brussels sprouts, winter spinach, onions. (This would make an excellent rotation for those with a limited space given to vegetable culture.)

3.—Shallots, broad beans, broccoli, short-horn carrots. (Keep some straw or other light covering ready to protect these from frost in autumn.)

Some crops, turnips, radishes and annual spinach, like partial shade, between, say, rows of peas, or celery trenches. Keep the soil drained well in winter and moist in summer (this means deep digging), to keep the plants well supplied with food, to protect from frosts, and to exercise patience and care in planting out the crops. Sow thinly, prick out early, see that roots go down into the holes naturally and not doubled up, and plant firmly. Do not overcrowd and never waste space.

The owner of even a small garden can, by adopting the methods briefly indicated, obtain a constant supply of vegetables in a plot set apart for the purpose, without encroaching too far on space wanted for the flower garden.

The amateur should lose no time in making his s

THE high cost of tender bedding plants like geraniums and begonias has led to a change in the occupants of our summer beds. Gardeners are realising that there are hosts of equally beautiful flowers that may easily be raised from seed at home, and this at a fraction of the cost incurred when buying the usual bedding plants. Readers who possess a heated greenhouse will find it very fascinating to grow their own bedding plants from seed, besides having the satisfaction of knowing they are saving money at the same time. All the following plants are easily raised, and should be sown in shallow boxes in a warm greenhouse from now onwards, being, of course, hardened off in the usual way before planting out.

Verbena.—Among the most showy of all annual plants, with fragrant heads of richly coloured flowers. The trailing growths should be neatly pegged down, so that they will cover the largest possible space.

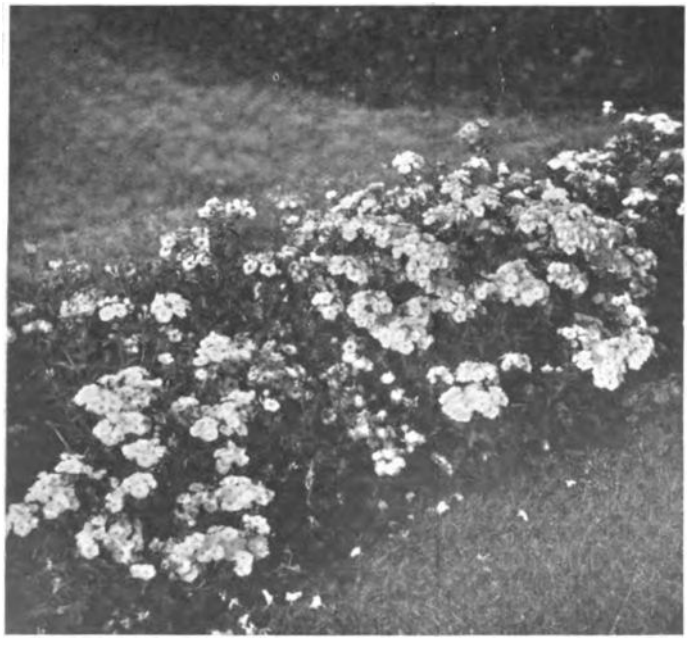
Nemesia.—Brilliant! That is the only word that can possibly describe a bed of these, either in mixture of colours or in separate shades. Orange was the original colour of the nemesia, but now almost every shade is available. N. Suttoni is the finest strain, forming fine bushy plants simply smothered with blossom and growing to a height of 12ins. to 15ins. Blue Gem is a pretty pale blue variety, and Twilight a blue and white bicolor of great charm. Nemesias should be given cool treatment, and need not be sown before the end of March.

Stocks.—There is little need to sing the praises of these fragrant and showy plants. The ten-week varieties are undoubtedly the most popular, and may be had in a number of distinct strains. All bear spikes of double flowers, the prevailing colours being rose, white, purple, pink, lilac, yellow and crimson. Early April is a good time for sowing, while they may even be sown outdoors towards the end of the month. Height varies from 1ft. to 2ft., according to strain of seed.

Salpiglossis.—For sheer gorgeousness of colouring these are hard to beat. They are of rather tall and lanky habit, but by close planting this fault will not be so noticeable. The trumpet-shaped flowers are of many rich colours, including crimson, purple, rose, scarlet and violet, while each is prettily marked with a network of veins on the inner side of the petals. Height 3 ft. to 4ft.

Mimulus.—For a moist, shaded bed these are very suitable plants, and will flower profusely over a long period. The blossoms are large, and heavily blotched and margined with red or crimson. A rich soil is necessary for the best results, and the seedlings should be planted at least 9ins. apart. Height 6ins.

THE DAINTY AND COMPACT NEMESIA IS ONE OF ANNUALS WITH ITS WID



FOR SMALL BEDS OR NARROW BORDERS THE ANNUAL PHLOX IS PARTICULARLY USEFUL. IT FLOWERS FREELY FOR MANY WEEKS AND MAKES A BRIGHT SPLASH OF COLOUR.

TS FROM SEED

g in the garden have undergone a decided change. of scarlet geraniums and blue lobelia with perhaps ionic effects. With the great improvement and choice of suitable bedding subjects has been greatly ction of plants which can all be easily raised from nd novelty to this year's summer bedding display. n from the numerous seed catalogues now to hand.

ASTERS ARE EXCELLENT FOR A BRIGHT DISPLAY.

Phlox Drummondii.—One of the best annuals for a small bed, and will thrive most in a sunny position. The large heads of gaily coloured blossoms are freely produced, and stand up well above the foliage. Growth should be pegged down in the way advised for verbenas, small hairpins being useful for the purpose if there is not a great number of plants to be dealt with. There are several strains on the market, of which we may mention cuspidata, with fringed star-like blossoms, 1ft.; grandiflora, bearing very large flower trusses, 1ft.; and nana compacta, a dwarf strain growing about 9ins. high.

Antirrhinums.—These need little introduction to the reader. Suffice it to say that they are quite indispensable in the modern garden, and that seed should be sown as soon as possible if early blossom is desired. There are many fine strains on the market of tall-growing, intermediate and dwarf Tom Thumb varieties.

Dimorphotheca.—This is rather an unusual South African annual, with starry flowers in the most vivid shade of orange. Even more beautiful are the hybrid forms, which display flowers in many pleasing colours besides orange, such as lemon yellow. They will flourish best in a sunny bed, and reach a height of about 9ins. or rather more under most favourable conditions.

Asters.—These, of course, are ideal plants for bedding purposes. There are many strains in cultivation, and each one is valuable. The three most pleasing for bedding, however, are chrysanthemum flowered, very dwarf and compact, 1ft.; Victoria, of pyramidal habit, 18ins.; and sinensis asters, with dainty single flowers of many pleasing shades.

Zinnias.—These must not be omitted, though it is true that some people find difficulty in growing them. Rich soil is an essential, and water must be supplied freely during periods of drought. Of modern strains the dahlia-flowered forms are undoubtedly the best, with tremendous flowers in many bright colours. These grow about 2ft. high, but there are also dwarf strains only reaching a height of 1ft.

Besides the plants noted above there are many more that may be used, including ageratum, in shades of blue, lavender and white (there are many fine compact varieties, such as Little Bluebird); kochia, a "dot" plant with finely cut foliage, which assumes a shade of rich crimson in the autumn; marigolds, familiar to young and old alike; lobelias, so very valuable for edging purposes; petunia, sweetly scented, and especially good for a sunny bed, and sweet alyssum, which is often sown under glass for the sake of early blooming.

MOST BRILLIANT OF OUR SUMMER FLOWERING ... OF COLOURINGS.

THE DAHLIA-FLOWERED ZINNIAS ARE NOW AMONG THE MOST POPULAR OF BEDDING PLANTS BY REASON OF THEIR VIVID COLOURINGS AND COMPACT HABIT.

NOTES ON THE FLOWER GARDEN

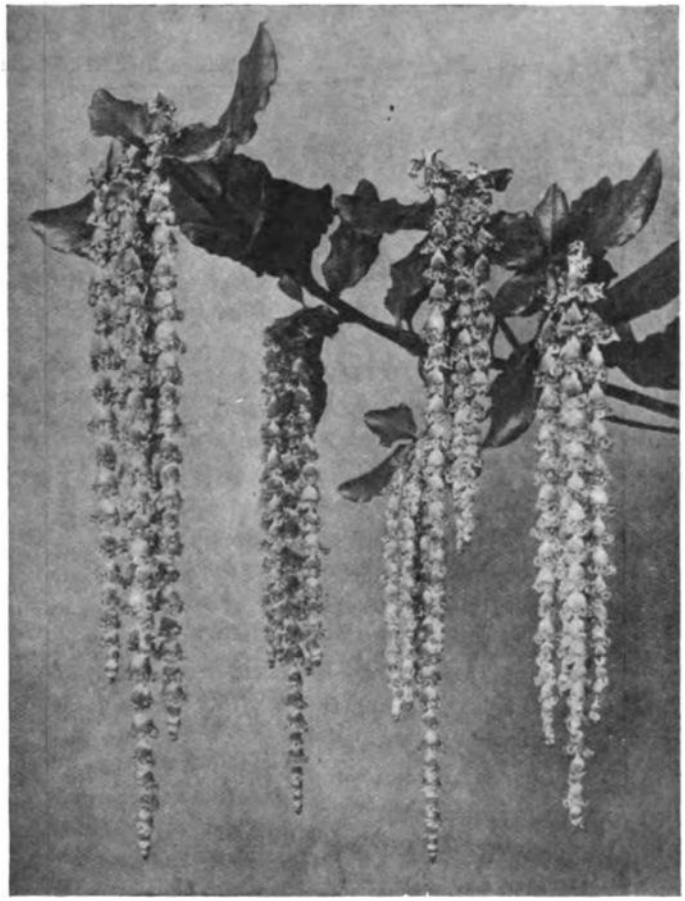
A Good Winter Flowering Evergreen Shrub.

TO lovers of rather novel and interesting shrubs, Garrya elliptica suggests itself as worth growing. As it possesses the dual quality of being evergreen and at its best in the depth of winter it is particularly useful and attractive. Although generally believed to be a shrub for southern gardens, it will grow quite well farther north if given some slight protection in the shape of a sheltering wall, against which it looks very effective.

Its native habitat is California, where it forms a small tree, but in cultivation in our gardens it rarely forms more than a bush from 8ft. to 12ft. or 14ft. in height. The conditions best suited to its requirements are a sunny position and a well drained soil that is not too rich. No pruning beyond necessary shaping is needed. The chief beauty of G. elliptica lies in the silvery grey catkins produced from December to February by the male plants; these catkins will sometimes grow to a length of 12ins., but even although they only develop to 6ins. or 8ins. they are still highly decorative; and I have occasionally seen small branches used in vases for indoor decoration.

The catkins borne by the female plants are not nearly so attractive as they rarely attain a length of 3ins. and are often hidden by the foliage. The leaves are opposite and rather leathery in texture with a very dark green upper surface and much lighter under surface.

Cuttings of G. elliptica inserted in July and August in sand in a frame where there is a gentle bottom heat, will root readily, and as the male plants are more often needed than the female, it is better to propagate by this means than by seed, which is freely produced. The plants raised should be grown on in pots until required for their permanent positions, as they transplant badly from nursery beds. —DUNHEVED.



GARRYA ELLIPTICA WITH ITS ATTRACTIVE CATKINS.

A Neat Plant for the Small Garden.

NOTWITHSTANDING their very unprepossessing name, the omphalodes are all worthy of a place in the smallest garden. Belonging to the borage family, they differ greatly in appearance one from the other, but all are pretty and interesting plants to grow.

A dainty little thing with grey-green foliage and small milk white flowers on stems about 12ins. high is Venus' navelwort (O. linifolia). It gets its English name—which, after all, is only a free translation—from the beautifully shaped nuts or seeds, which are characteristic of the family to which it belongs. The plant comes from Portugal, and from an April sowing it will flower during the months of June, July and August. More often than not it sows itself freely in the garden. A very different plant is the creeping forget-me-not (O. verna). Seen at its best in the partial shade of a thin wood, it produces its beautiful clear blue flowers with their white throats in the early spring. The leaves are broad, hairy and of a rich dark green. The plant revels in space in which it can roam about at its own sweet will. Omphalodes cappadocica or Luciliæ, as it is more often called, has large soft blue flowers in branching spikes some 6ins. long, with grey-green foliage. It is considered by many to be the best of the omphalodes, by reason of the beautiful combination of the blue flowers with the silvery foliage. It comes from Asia Minor and likes a soil rich in lime. Its great enemy, however, is the slug; but it is worth while doing all one can to protect the plant from these pests, for it amply repays one by its great charm. It seems to be happy on the moraine in a northern aspect. The flowers above their rosettes of silvery green foliage are produced in summer.

Though Robinson mentions a fourth omphalodes (O. nitida), this does not seem to be at all a well known plant, and one may search in vain for it among the nurserymen's lists.—EDWARD CAHEN.

Bulb Notes.

Protective Measures to be Taken Now.

THE recent sharp spell of frosty weather will serve to remind us that some protection against the bitter winds of March should be given to bulbs which will then be heading up for flower. Generally speaking, neither daffodils nor tulips will come to much harm unless they are exposed to high winds or heavy snow when they are actually in flower. There are, however, exceptions to this rule. Varieties of both species vary considerably in the brittleness of their stems: some will bend to the ground while others snap off "as short as a carrot." A few light twigs pushed in among the flower-stems will afford all the support necessary, but choice varieties should be given a tie when the spikes are 12ins. or 15ins. high, for it is very exasperating to lose them at the last moment of growth, and the little time necessary for the operation will be afterwards counted as well spent. Those fortunate people who grow N. triandrus calathinus should give the *bulbs* all possible protection from frost, as the constitution of these delightful little flowers—and for that matter most of their hybrids—is delicate and forms an exception to the general hardiness of the family. Early-flowering gladioli (The Bride, Peach Blossom, etc., and others of the nanus, Colvillei and Herald types) call for something more than the above if they were planted in autumn. Already their leaves are several inches high and a cutting frosty wind will sear them badly, check the flower and badly weaken the growth. Laurel, yew or other evergreen twigs should be employed to shelter them until mid-April. Irises, Dutch and Spanish, do not appear to suffer much harm from cold, although it cannot help them to have their foliage "cut" and withered by frost, and there can be no question that a few evergreen twigs stuck around them will amply repay in the quality of the subsequent bloom.

Ranunculus and montbretias, too, should be protected from frost by covering with leaves or straw, but anemones are quite hardy and may be left without protection with impunity. —HERBERT G. LONGFORD.

Replanting & Renovating Box Edgings.

THE box plant is slow-growing, and forms a splendid hiding-place for slugs, but with many lovers of gardens, especially old ones and where formal designs are in favour, the plant is much appreciated. I have had to deal with more than a mile of box edging in a vegetable garden; it was preferred to any other form of boundary to path and border, and I never found any undue robbery of adjoining crops; in fact, the ground was cropped close up to the edging. In reality, I think the box is one of the most economical of edgings to such borders, as it only requires trimming twice a year—in May and September; or, if cut once, late in February, so that the new leaves will not be seared by late frosts. Where the edgings have become ragged, unkempt or otherwise unsatisfactory, lifting, dividing, trimming and replanting are the only way to put matters right. Box edgings 1ft. to 18ins. in height are neither necessary nor desirable in any garden, and where such exist their condition is owing to neglect as regards annual cutting and replanting at an earlier stage. Such high, ragged box edgings cannot be lifted and the plants satisfactorily divided and replanted. It is where the edgings are now beginning to get out of order a little that replanting will be beneficial. In the case of old ones—real veterans—cuttings should be taken of young shoots about 6ins. in length and inserted in a mixture of leaf-soil, loam and sharp sand on the north side of a wall or fence during August and September. The first-named month in the northern and the last-named in the southern counties. The younger edging plants may be lifted during February, trimmed, divided and replanted to form a very narrow

Digitized by Google

edging. The ground must be thoroughly clean and the box slips planted in an upright position, the soil being well firmed around their roots. The work should always be done from the border side and not from the path. —HANTS.

The Caffre Lily.

THE Caffre lily or crimson flag is a most valuable bulbous subject, either for the border or level bay in the rock garden, while it is also useful as a pot plant for the cool or cold greenhouse.

It produces strong spikes of showy globular crimson-scarlet flowers during October and November, and in addition makes a fine display outside. In 1921 a pink form, known as Mrs. Hegarty was exhibited before the Royal Horticultural Society, and gained an award.

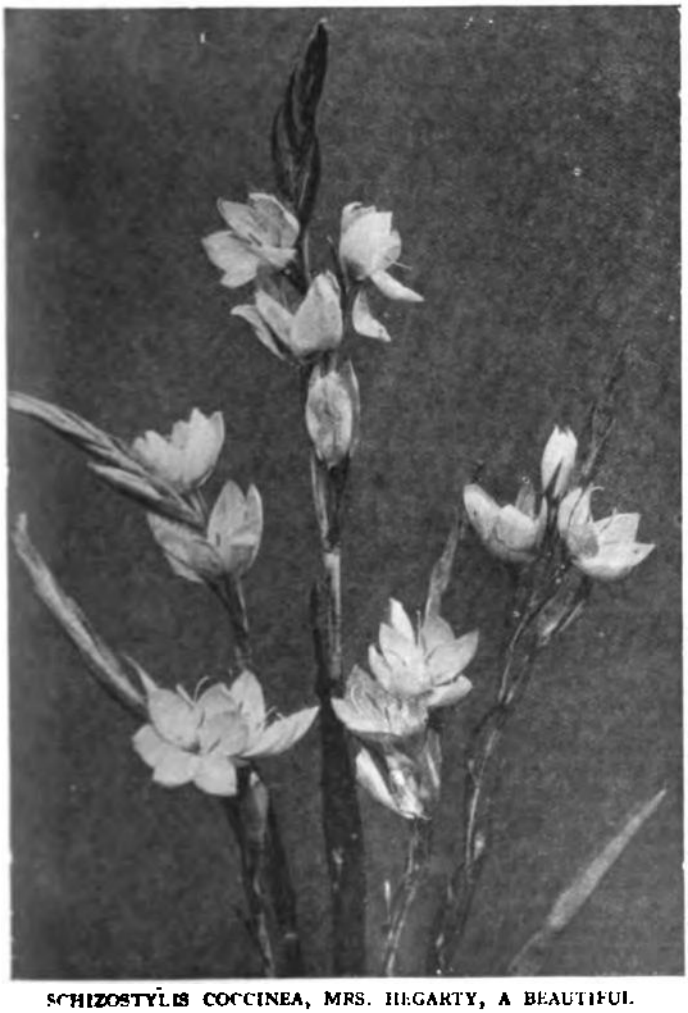
The schizostylis enjoy a good depth of soil, preferably that of a loamy nature, but any ordinary garden will suit them. After a few years the clumps will become somewhat congested, the flower spikes will be few, and the quality of the blooms poor. When this stage is reached, the roots must be lifted, divided and replanted, but owing to the fact that they are always more or less growing it is difficult for many gardeners and amateurs to decide on the best time for such work to be accomplished. After various experiments, I have found that March or very early in April is the ideal time to lift and divide. When lifted, the plants are pulled into pieces, or small clumps of three or four bulbs, and then replanted 6ins. or so apart. If the same site is utilised it ought to be dug 2ft. deep, and afforded a dressing of manure, or a liberal sprinkling of bone meal, because it will be several years before the roots are again disturbed. If we experience a dry summer, the roots should be freely supplied with water, then a wealth of spikes will be seen in the autumn. —CHEPSTOW.

A Shrub Well Adapted for the Small Garden

A FINE shrub occasionally to be seen under the name of plumbago, is Ceratostigma Willmottiæ a close relative to our old friend P. Larpentæ, a dwarf spreading plant, but C. Willmottiæ is shrubby and is capable of attaining a height of 5ft. or even 6ft., when well grown. It is a native of China, from whence it was introduced in 1908, and since then it has found considerable favour in gardens. The growth is rather wiry, and the light blue flowers resemble those of the plumbago, while the flowering period is extended over a great part of the summer and autumn. It is well adapted for the small garden, and although it will reach the height stated above, I have succeeded in keeping plants quite small on the rock garden by cutting it down nearly to the ground level each spring.

It will thrive in almost any soil, but it should be grown in full sunshine, and so far it has proved quite hardy. It can be increased by cuttings during the month of July and August.

C. Willmottiæ is a useful subject for the cool greenhouse; it makes a nice pot plant, and is rarely out of bloom. Such examples produce plenty of cuttings, which root readily in a little warmth. —T. W. B.



SCHIZOSTYLIS COCCINEA, MRS. HEGARTY, A BEAUTIFUL ROSE-PINK CAFFRE LILY.

THE YELLOW BLOOMS OF HELENIUM AUTUMNALE.

Helen's Flower.

THERE are few border flowers of greater value than the helenium (the English name of which, by the way, should be, according to Mr. W. Robinson, sneezeweed, instead of the prettier one that heads this note!) in all its varieties. It is perfectly hardy, not at all particular as to soil (although, in a very dry situation, it will not attain its proper height and its foliage will flag badly in hot weather unless regularly and thoroughly watered), while its big clusters of rich-coloured flowers are most effective.

Of the taller heleniums—that is to say, those that grow from 4½ft. to 5ft. high (all of which bloom between mid-August and early October)—H. autumnale has yellow flowers; Riverton Beauty and Gartensonne are improved varieties of the type, their colour blossoms being deeper in tone and having velvety brown centres; the new Bronze Queen is not dissimilar, but the yellow is of a tawny shade. Still more attractive, however, are the varieties that have crimson or brownish red flowers streaked or shot with gold. H. autumnale rubrum is the oldest of these, and its dark crimson is very beautiful but the colour of Riverton Gem is rather brighter and the gold streaks more marked. There is, too, a newer introduction, Mrs. Bradshaw, which has fine deep red flowers; this has the advantage of a longer flowering season than most of its kin, but it can scarcely be classed among the tall heleniums, as its height does not exceed 3ft or 3ft. 6ins.

Helenium pumilum is dwarf, seldom growing more than 2ft. to 2ft. 6ins. high; its flowers are lemon yellow. Those of H. p. aurantiacum magnificum are deeper in shade; those of H. p. cupreum are red-brown streaked with gold; and the handsome variety, Crimson Beauty, is the colour its name implies.

Heleniums in variety are particularly effective massed in front of a shrubbery. In the border they will harmonise well with the earlier Michaelmas daisies—lavender or purple-blue—or they may be combined with torch lilies and early chrysanthemums.—R. E.

LATE FEBRUARY in the VEGETABLE GARDEN

FEBRUARY is a month of great possibilities, but they are not always realised. There is so much that might be done, but we are almost entirely dependent on the character of the weather. Especially towards the end of the month a favourable opportunity of getting seeds sown and plants set out should not be neglected in case the month of March is a bad one for the purpose. Obviously the work here advised to be done must be subject to its being in accordance with the weather.

What is Possible in February.

Seeds which may be sown outside are early peas, broad beans, spinach, radish, short-horn carrots and parsnips. All of these will, of course, be sown in the place where they are to mature. Seed beds may also be sown of cabbages (both red and white), cauliflowers, brussels sprouts, lettuces and leeks. If found necessary, parsley may be sown and it may sometimes be advisable to try to steal an early crop of turnips on a warm border. If the weather is good during the last week of the month, there need be no hesitation in getting in a few onions.

When Planting is Possible.

If the weather is favourable for sowing it surely will be so for planting, and in that case the following may be dealt with : shallots, potato onions, garlic, onion sets, chives, onions for seed, as well as parsnips, carrots and beet for the same purpose, onion plants from the autumn sowing, red and white cabbages, lettuces, Jerusalem artichokes, horseradish, rhubarb and herbs. On a specially warm border and in the event of the plants being covered from frost a few early potatoes may be tried, but too much dependence must not be put on this early planting. For practically all these crops a fairly fine tilth will be needed, though not so fine as for seeds. Be always on the look-out for a sowing and planting opportunity, because the more that can be safely planted and sown in February, the less there will be to be done in the busy month of March.

An Alternative to Outside Cropping.

Those with a greenhouse may make full use of this during this month for bringing along many of the crops already referred to. If no inside sowing was done during January, it should be done now, and there are others to be dealt with as well as successional sowings. The following may be sown in the greenhouse now : onions, cabbage, cauliflower, lettuce, Brussels sprouts, peas, broad beans, parsley, celery, leeks, and at the end of the month, some tomato seeds may be sown for growing outside in due course. Early potatoes may also be placed in the greenhouse to bring them along, if necessary, while those who wish for some early autumn broccoli or savoys may sow a pinch of seeds.

Other Work in the Greenhouse.

In a greenhouse partly devoted to the vegetable part of gardening, this month will be a busy one, for many of the seedlings from last months' sowings will need to be transplanted into boxes. This is work which cannot be delayed without jeopardising the success of the venture. A sprinkling of lime in this soil will be an advantage. Cucumbers, tomatoes and melons for fruiting in greenhouse may still be sown and the plants from an earlier sowing potted along. Those who can wait for results from seeds may now sow rhubarb, seakale and asparagus in the greenhouse for planting outside during April, while those who wish to experiment with real seeds of potatoes may also sow these.

Soil Tillage and Kindred Matters.

The work of soil cultivation may still be pushed forward. If sufficient trenching has not been done, this should be remedied, it being better to trench a fixed portion of the garden each year. When this has been done the remainder of the soil may be dug to a depth of a foot. It is late now for ridging, but not too late for the preparation of the trenches for celery, leeks and stations for runner beans and peas. This work may be done when it is not possible to get on with any cropping. When cropping is possible that should have the precedence, and no opportunity should be lost of getting the surface to a fine tilth for immediate cropping. There is no advantage in reducing to a fine tilth any soil which is not due for early cropping.

It will in many cases be an advantage to fork over the soil which was treated in the autumn, but this should only be done shallowly so as not to disturb the manure or bring sticky soil to the surface. Soil which has been ridged may be levelled with the fork and will usually be in fine form for cropping. The work of reducing a soil to a fine tilth is done with the hoe, fork, or drag, according to the character of the soil, and finally with the rake. Where manuring was not done in the autumn it must be attended to now, but at this time only very well decayed manure should be used for all general purposes. Where there is need for lime in the garden the work of spreading it after the digging must not be longer delayed so that the cropping will not follow too closely on this work. The use of soil fumigants should be done a little in advance of cropping.

Attention to the Root Crops.

All roots in store should be looked over so as to prevent too much loss by rotting or by the roots starting into growth. Remove all bad roots and rub off or cut away any growth from them, setting these aside for use as early as possible. Any roots which are still in the ground, such as parsnips, Jerusalem artichokes, etc., may now be lifted and stored as it is probable that the soil will be needed for cultivation. If the rows of celery and leeks are also in the way of soil cultivation, they also may be lifted and be heeled in some odd part of the garden. If not already done, the sets of potatoes, shallots, etc., should be picked out for planting, though this should really have been done in the autumn, and in the case of potatoes, when they were lifted. A look-over of any seeds which were saved, is also due, and it should not now be necessary to emphasise the need of sending without any delay the order for seeds and sundries needed for the whole year.

Care of the Frames.

Give abundance of ventilation to vegetable plants in the cold frames, drawing off the lights whenever possible so as to harden them thoroughly. Watering must still be done only on the morning of a sunny day, and it will help the plants immensely if the soil is loosened between them. Cover when necessary from frost, but do not leave these covers on a moment longer than is absolutely necessary. Remember always that dampness rather than frost is the real enemy of these plants and often takes a great many off. Remove any plants which have damped and sprinkle the station with lime.

Miscellaneous Matters.

Already I have given a full programme of work, but if time can be spared there are several items which might be attended to. Among them I might briefly mention cutting and trimming pea and bean sticks, the preparation of labels, sifting soil for seed sowing, making and repairing seed boxes, cleaning and repairing tools, turning the rubbish heap, burning that portion which is not suitable for rotting and digging into the garden, wheeling manure, etc., on to the soil, repairing paths, planting box edges, trimming hedges, removing and burying all dead leaves on growing plants, and giving the garden generally a more neat appearance. W. F. R.

Salsafy.

THIS vegetable is often referred to as vegetable oyster when served at the dinner-table. The plant is one which can be grown to perfection in a naturally light soil ; but in a heavy loam the roots are often found to be forked where little attention has been given to the preparation of the soil previous to the sowing of the seeds. The object of the cultivator is to procure straight, not forked, roots, long and clean. Very deep digging or trenching is essential, especially where the soil, as stated above, is of a heavy, retentive nature. All soils for this crop are the better for being autumn trenched and manured then ; and even in the autumn strawy manure should not be used, and the lighter the soil the more the manure is rotted the better. If manure is to be applied now, in spring, it should be buried deeply, thoroughly mixed with the soil quite 1ft. below the surface, then the roots of the plants go down deeply. Rather than mix manure generally with the top soil I would grow the plants without any manure and pay extra attention to the deep tillage of the soil, whether it be light or heavy. Sow seeds early in March, at the end of April and the third week in May. A few rows well treated will be much better than many rows of plants given very ordinary treatment. Bury the seeds 1in. deep or so, thin out the resultant plants to 1ft. apart for extra fine produce, and refrain from disturbing the soil deeply during the summer months so as to avoid interference with the downward course of the now rapidly growing roots. The latter should be ready for lifting in batches at the end of October and storing in sand. But the soil for the reception of the seeds cannot be prepared too early now, if it is in a suitable condition.—G. G.

How to Grow Good Parsnips.

IT is customary to sow parsnips early. Some gardeners sow in February, but from my own experience, I think that better quality roots are obtainable from April sowings. It depends a good deal of course upon the climate and the season. The soil is also an important factor.

If parsnips are overgrown they are coarse and deficient in flavour. In any case they are always best flavoured after they have got a slight touch of frost.

Needless to say, the soil must be deep, somewhat moist and moderately well manured to grow parsnips to perfection. No rank manure should be given just before sowing. Preferably, a plot that was heavily manured the previous season should be used. A suitable fertiliser to apply at time of sowing, and which should be well forked into the soil and evenly distributed, is 2½oz. superphosphate, ½oz. muriate of potash, and ½oz. sulphate of ammonia, per square yard.

If basic slag is used instead of superphosphate, a suitable mixture for application at time of sowing would be 3oz. or 4oz. slag, ½oz. nitrate of soda, and 2oz. potash salts. The nitrate of soda would generally produce better results if applied in separate and small dressings during the growing season. These quantities are for one square yard.

Parsnips require plenty of room, say 14ins. to 16ins. between the rows. To obtain very fine roots of a great length, make holes at regular distances of 8ins. to 10ins. apart,

Digitized by Google

in the rows, with a crowbar, or a sharp-pointed stake about 2ins. to 2½ins. in diameter, and from 2½ft. to 3ft. deep. Fill the holes with a mixture of fine leaf-mould, sand (fine) and a little of the artificial manure. Put a sprinkling of sifted garden soil over these materials and within an inch of the surface level, place two or three seeds in each hole. Cover with sifted soil.

When the seedlings are large enough to handle, pull out the two weaker ones, and leave the best plant in each place.

Parsnips may be grown in any kind of light soil, provided it is of sufficient depth, especially if this plan be adopted. It is of no use trying to grow parsnips on shallow soils that have not been dug to a greater depth than one spit.—J. W.

Sow Onions in Heat in February, Plant Out April—May.

WHERE spring-sown onions usually fall a prey to grub or "fly," autumn sown plants may be planted in March or April, with every prospect of success. Instead of autumn plants, we may use seedlings sown under a little heat in February. For exhibition purposes the seeds must be sown early in February, if not in January; but for utility purposes, February sowings will be early enough. The most important point about these sowings is that the seedlings must be kept growing all the time. They must not be checked in any way, as that tends to make for "thick necks" and bolting. It is well not to sow in soil that is too rich, nor to have the frame too hot.

The seeds may be sown in boxes, and the seedlings, when large enough to lift with a ball of soil at their roots, may be transplanted into larger boxes, or into a frame in rows two or three inches apart.

The open ground in which they are to be planted at the end of April or early in May, should be well prepared in advance.

The seedlings must be well hardened off before planting out, and this circumstance and the nature of the weather will to some extent determine the time to plant out.

Onions like a fairly firm soil, and the bed or plot should be made moderately firm. The plants must not be planted too deeply; but care must be taken to make a hole just deep enough and wide enough to take the fibrous roots in their full spread, but with the soil still adhering to them.

In order to facilitate the work of lifting and transplanting, let the seedlings be well watered the previous day. Use a small hand fork, or a flat trowel, and take care not to injure the rootlets.

The newly planted seedlings may be shaded for a day or two, if the weather is not soft and mild, but once they take root in their new surroundings, this should be removed.

It is useless to give stimulating manures before the plants take root and grow. Dressings of nitrate of soda may be given at intervals during the growing season, and well watered in, if there is a spell of drought in June, for instance. Onions can be grown up to 2lb. in weight this way.—W.

Staking Newly-Planted Fruit Trees.

FEW trees will be planted after this date. Where everything is convenient, wise cultivators plant their fruit trees in late autumn. It is never wise to stake them securely at planting time. A temporary support is necessary to keep them from being loosened in the soil, but such support must not "hang-up," as it were, the roots in the soil. Many young trees are crippled in this way, through a little want of thought, when they are newly planted near to walls and their branches forthwith nailed in position or tied to the wires where walls are wired. The roots do not sink down with the freshly moved soil. Permanent stakes may be fixed at the time of planting, and now is the time to cut away those temporary strands and replace them with more permanent ones. Due regard should be given to the way in which the strong string is used. It must not be fastened tightly, or the bark of the young stems will be bruised. A few twists of the twine made between the stem of the tree and the stake will effectively prevent any rubbing of the stem and stake together. In open orchards, where the young trees are exposed to strong winds, half-standards and standards should be supported with three stakes fixed tripod fashion, then the tree will have a chance to grow upright, the support being ample whichever way the wind may blow.—CHRISTCHURCH.

WHAT OUR READERS SAY

A TRUE BLUE ACHIMENES.

SIR,—Can any of your readers give the name of a *real blue* achimenes whose blossoms are the colour of a deep blue delphinium, without any trace of red in the colour. I know the white, the scarlet and the bluish purple varieties, but cannot trace the *true blue* I had in quantities on the Continent many years ago. If still obtainable, what firm lists it?—A. BULWER, *Dalling*.

REMEDY FOR WOOLLY APHIS.

SIR,—With reference to the correspondence regarding remedies for woolly aphis, when some newly planted standard apple trees were badly infested with this pest I was advised to paint the affected portions with ordinary paraffin, using a fairly hard brush. This was done early in the summer, and proved immediately effective in completely eradicating the trouble. Although this was twelve years ago, there has never been a sign of the pest in the garden since.—ARTHUR E. FARRELL, *Berks*.

ROSE MISS WILLMOTT.

SIR,—I was very pleased to see, in THE GARDEN of February 12th, that Mr. Easlea included in his list of eighteen really reliable roses the variety Miss Willmott.

In my opinion, it is the finest of all roses, for the following reasons: (1) it is vigorous and resists mildew; (2) it flowers very freely; (3) the blooms are of good size and substance and always of perfect shape; (4) its colour, cream, is very pleasing; (5) the blooms never "egg" in wet weather, as many do; and (6) it is slightly fragrant.

I cannot understand why this excellent rose is so seldom seen—at any rate, in our northern counties.—W. V. PERCIVAL, *Chelford, Cheshire*.

THE CHRISTMAS DAISY.

SIR,—In reply to your correspondent, Mr. E. A. Saunders (THE GARDEN, February 12th), I think I obtained my Aster grandiflorus from either Messrs. Barr and Sons or Messrs. Amos Perry, but as it was a good many years ago I am not certain which it was, and it does not appear in their latest catalogues. I find it, however, in lists of Messrs. Veitch and Sons (Exeter) and Messrs. Thompson and Morgan (Ipswich), but I have not got the most recent editions of these catalogues. No doubt, any one of the firms named would procure the aster, as it is not really scarce, but simply rather out of fashion.—R. E. H., *Bath*.

PEAT IN THE GARDEN.

SIR,—I read with great interest the article on Shrubs for the Small Garden, by "Dunheved," in your issue of February 12th. His selection of shrubs and general advice is excellent, but why does the author insist so much on the use of peat in the planting of hamamelis, olearia and magnolia? I have various species of all these genera growing in soil that varies from heavy loam to light loam without the addition of any peat. Peat, in fact, has become a fetish with some planters. On all sides its incorporation with the soil is advised with rhododendrons and other ericaceous plants, and many alpines, such as Gentiana sino-ornata. It is said that its use is to add humus to a soil that lacks it; but leaf-mould is far more easily obtained in most gardens than peat, and its feeding properties are certainly greater. There is only one plant for which I have found peat essential, and that is Andromeda polifolia, a very charming but difficult shrublet, particularly on the East Coast.

Peat makes an ideal mulch, for it is light and porous and does not disintegrate so quickly as leaves or leaf-mould; but the insistence on its incorporation with the soil is a mistake. It only increases the difficulties of the gardener who has to buy a great deal of his gardening material. Careful tilling of the soil with the addition of leaves, leaf-mould, and a little grit in heavy soils, are all that are necessary for the successful cultivation of almost all shrubs.—R. H., *Edinburgh*.

SWEET PEAS AND STREAK.

SIR,—In your issue dated February 5th, "C. H. W.," writing in "What Our Readers Say," raises a question which, although impossible to answer in a definite manner, is important to every sweet pea grower. He says, referring to a previous article of mine, "before you can obtain those beautiful blooms, one has to find a cure for the *streak* which is present in *nine out of every ten gardens*." If "C. H. W." means that nine out of ten growers are seriously troubled by streak, I cannot agree with him. If streak or any other disease was even fairly common, it is reasonable to surmise that sweet peas would not be nearly so popular as they are; indeed, exhibitors, both "trade" and amateur, could not be so consistently successful year after year if streak was so prevalent as "C. H. W.'s" note would lead one to believe. Far too much prominence has been given to streak in the columns of the horticultural Press in the past; in my opinion, out of all proportion to the frequency with which it occurs. Very probably in nine out of every ten cases where streak is blamed as the cause of failure, the real cause is something quite different. It is convenient to have a kind of "mystery" disease about which little is known and which may be blamed in nearly every instance when the plants succumb. The more I see and hear about streak the greater my conviction grows that it is *not a disease at all*. With almost any disease in the plant or animal world we associate infection in some form or other, yet I have never had positive proof that this so-called disease can be "carried" or transmitted from one plant to another in the seeds, in the air or soil, by actual contact, or that it can infect plants grown in soil which has contained "streaky" specimens the previous year. If it is a disease, surely proof of infection would be forthcoming, and why should greenhouse-grown plants be immune? I have yet to hear of a genuine case of streak among indoor sweet peas. Further than this, expert plant pathologists have examined under the microscope plants which were apparently very badly diseased, and in all

Digitized by Google

instances were unable to find any diseased tissue.

If it is not a disease, then what can it be? My own answer is that it is probably the usual manner (apart from old age) in which sweet pea plants die off, and that it may be due to not one, but many causes. The symptoms usually associated with streak are the changing of the colour of haulm and foliage from green to a streaky mottled greenish yellow, then to brown, accompanied by deformed and stunted growth and the gradual (or sometimes rapid) collapse of the plants. Many conditions will cause the plants to die in this manner, such as a very bad attack of green fly, waterlogged soil, acidity, sourness, too much fertiliser in the soil (either artificial or natural manures), soil pests, and last, but by no means least, sudden weather changes. Broadly speaking, streak may be nothing more or less than a form of "acute indigestion," probably connected in some way or other with the colonies of beneficent bacteria present in the whitish swellings called nodules, found on the roots of all members of the pea or legume family. I feel confident that this streak problem will be solved by someone approaching it scientifically from the standpoint of the health of these bacteria rather than the assumption that streak is a disease.

One may find occasional "streaky" plants among sweet peas grown on ploughed land with no manure, a larger percentage among cordon or exhibition-grown plants, and even among culinary peas. Sometimes, but not often, a whole batch will die off, or part of a row, while usually only a stray plant here and there is affected. I do assure readers that after many years' experience my own losses in this way have been negligible, not 1 per cent., and I believe this to be a true guide to the percentage of losses when a general average is taken.

What we know about the disease, or so-called disease, seems all too contradictory, and while I know of no cure for affected plants, I can tender preventive measures which I have found effective.

Do not hesitate to plant sweet peas again on ground where streak has appeared the previous season, but find out first if the soil is sour, lacking in lime or waterlogged, and correct it. Dig deeply (trench if possible) early in the autumn, incorporating good well rotted manure, not in layers, but well mixing it in. Do not bring animal manure nearer than 9ins. of the surface. If the soil is cold and wet and inclined to become waterlogged, provide effective drainage by throwing into the bottom of the trenches crocks, stones, hedge clippings, garden refuse or anything similar. It will be all to the good if the plot can be moved all over. Later on, fork in a fair dressing of lime in the surface layer if the soil needs lime. Make a point of always transplanting robust, healthy seedlings, preferably autumn sown, and do not "feed" them in any way until flower-buds appear. A plant with a strong, hardy constitution and a good and extensive root system when firmly transplanted will "take some killing." Support the seedlings early, do not let them blow about, and keep the hoe going round them until about the end of May, when a surface mulch of loose decayed horse litter or spent hops should be applied round their bases to keep the roots cool and conserve the moisture. Disbud the first flower-buds for a week or ten days, and at intervals later on, to impart additional strength to the plants.

Endeavour to provide all the nutriment necessary when preparing the soil rather than rely on applications of fertilisers during the growing and flowering period. The surface mulch will in an average season make watering unnecessary except during very dry spells. Use soft water always, never well water or cold water straight from the tap, and most carefully avoid overfeeding and over-watering. Keep a sharp look-out for green fly, especially when the plants commence to show flower-buds. Do not let them obtain a hold on the plants or the whole batch may be spoilt.

One factor cannot be foreseen or guarded against, and it is usually the chief cause of the plants becoming "unbalanced," this is sudden changes of the weather from cold to hot and *vice versa*. Sweet peas are not natives of these islands, and although they have been grown here for over 200 years, apparently they have never quite become used to our peculiar climate.—C. H. A. S.

PERGOLAS OF SIMPLE CONSTRUCTION

ALTHOUGH the construction of a pergola should be of a substantial character, there is no reason why it should not be easily made, and also made in such a way that a maximum of effect can be gained with a minimum of labour. The simplest form of construction does away with a multitude of joints and provides for a number of easily made units which are quickly assembled together. The two forms of pergola illustrated at Figs. 1 and 2, are made in a similar manner, although they give a totally different effect, the units of construction being shown at Fig. 3.

To begin with the pergola at Fig. 1, it will be necessary to provide the uprights as at Fig. 4, the connecting lengths as at Fig. 5, and the top lengths as at Fig. 6. It will be seen that the uprights are made up with two outer posts, A, two rails, B and C, and are filled in with square trellis, D and E. All the material can be obtained machine planed to the required dimensions, so that the various parts only need fitting together. For the posts, provide two 8ft. 10in. lengths of 2in. by 2in. wood, and for the rails two 20in. lengths of the same material. The rails are tenoned into the uprights as shown in the separate detail at Fig. 7, suitable mortises being cut in the posts as shown in the side view marked A. The marking should be done with the posts and rails placed side by side, the measurements being shown in Fig. 4. The tenons should be approximately a third of the thickness of the wood, ½in. wide will suit for the present purpose. Gauge these marks off on the ends of the rails and on the posts and then proceed with the cutting as shown in stages at Figs. 8 and 9. The easiest method of cutting the mortises is to use a chisel of the same width as the thickness of the tenon; it is therefore as well to set the marking gauge to the chisel in case it is a trifle larger or smaller than the measurement required. First of all make a V-shaped cut, working from the centre of the mortise each side, as at 1, Fig. 8, and continue with the straight side of the chisel towards the centre of the cut until the outside limits of the mortise are reached, leaving about ½in. to be trimmed off later, this stage is shown at 2. The wood is now turned over on the other side and the method repeated as 3, and this leaves the trimming down, as shown at 4, the chisel being held with the straight side on the outside, as indicated.

The method of cutting the tenons as shown at Fig. 9, consists of accurate marking, as at 1, then sawing on the waste side of the line, as at 2, first from each corner down to the shoulder, and then the shoulder, as at 3, leaving the complete tenon, as at 4. The tenons of the rail C are not left full width, but are sawn across the diagonal as at Fig. 7, to allow for the tenons on the ends of the connecting lengths. The rails are now ready to glue up, but in order to pull the joints up close, and secure them at the same time, holes, ½in. diameter, should be bored through the tenon and sides of mortise for the insertion of pegs, as at Fig. 10. The pegs are 3ins. long, tapered from five-sixteenths diameter to ½in., and the hole in the tenon slightly

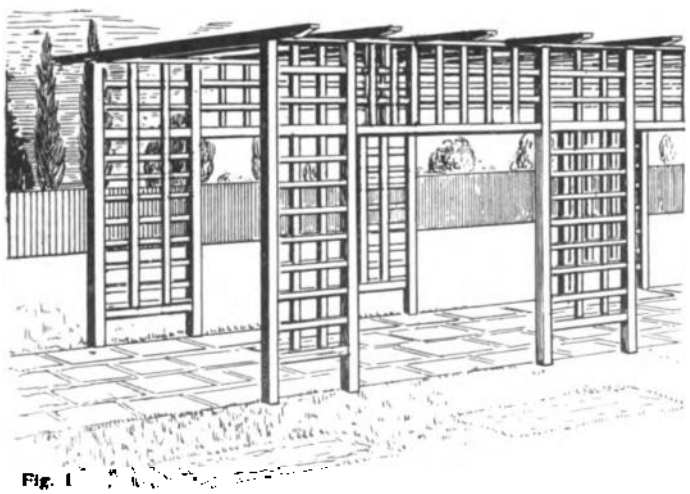

Fig. 1

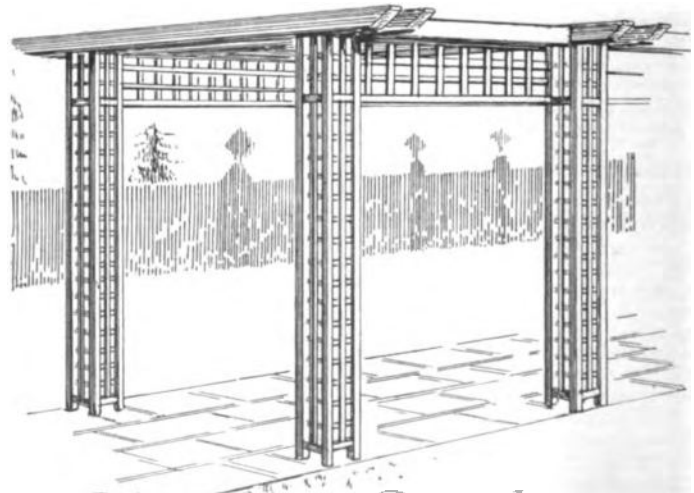

Fig. 2

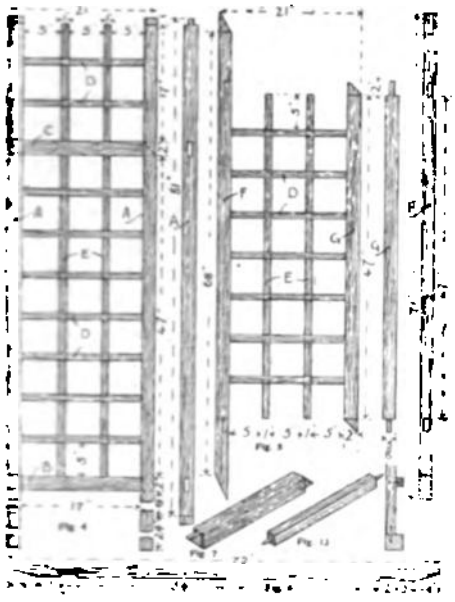
Digitized by Google

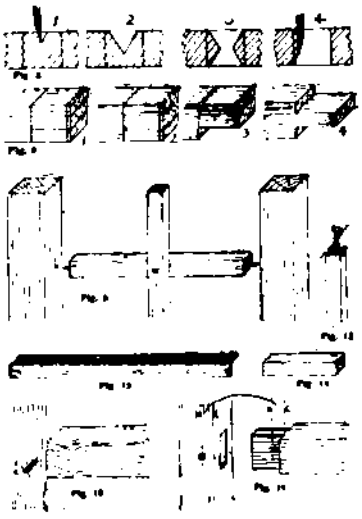


nearer the shoulder than the hole in the mortice; this is shown at Fig. 11, and has the effect of pulling the joint up quite close.

The horizontal lengths of the square trellis are cut from wood 1in. square, to the exact width between the uprights and are attached to the uprights with nails, these being driven in the ends as at Fig. 12, and the ends cut off with a pair of cutting pliers to leave points as at Fig. 13. The space between the trellis lengths is 5ins., this, with a thickness of 1in. between will give a distance of 6ins. between the nails, and although these spaces may be marked off with a rule, or wood template, as at Fig. 14, it is more satisfactory to use a length of tinned iron sheet as a template, this is shown at Fig. 15. When all the holes have been bored in the posts, fit the upright lengths of the trellis between the rails and then place the parts together, first glueing the ends of the tenons. Use a mallet to drive the two posts together and then insert the pegs, first dipping them in glue and afterwards driving them in.

The same procedure is followed with the connecting lengths at Fig. 5, but the top lengths F are intended to connect up together on the top of the upright frames, hence the ends are mitred. The mortises only go half way through. The lower lengths, G, are tenoned into the upright posts, the ends of the tenons being cut off along the diagonal to fit in the space left for them. The rest of the work is the same. There is no difficulty with the top pieces as shown at Fig. 6, the notches are 2ins. wide and ½in. deep, and they are nailed to the top pieces, F, of the connecting lengths.

The wood should be coated with creosote or some other wood preservative, and it is advisable either to char the lower 2ft., which goes into the ground before applying the creosote, or to coat it with pitch. When erecting the pergola, mark out the ground and



cut the holes for the uprights, place in position and support with suitable lengths of wood placed diagonally, and true each pair of posts before filling in the holes.

The pergola shown at Fig. 2, is composed of upright columns made as at Fig. 3, the construction is just the same as the other, but the tops of the columns are joined by pairs of lengths in both directions. Wood 2ins. by 2ins. can be used, but 3ins. by 2ins. material would look better.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Propagating Begonia Gloire de Lorraine and its Type.

In addition to propagating these plants by the usual method of cuttings taken from the base of the plants, they may also be increased by leaf cuttings. During February and March, select good healthy leaves that possess a growth eye, or bud, in the axils; remove with a heel and insert about ½in. deep in pots, in a mixture of equal parts of coconut fibre and silver sand, and plunge in brisk bottom heat, not necessarily in a close case. These readily root and in a short time throw up a number of growths. Plants raised in this way grow much stronger, are better furnished and produce finer flowers than those propagated in the usual way. Old plants after flowering should be rested in a slightly lower temperature—not dried off—previous to growing on another season.—C. N.

Propagating Tradescantia.

This very old but useful hanging plant still holds its place in many greenhouses. A sure and successful way to root cuttings—much quicker than in the ordinary flower-pots—is to dress each cutting with a clean cut to a leaf joint, then insert them into a jam jar or similar vessel half full of water, place on the shelf near the glass. Be sure that the water is kept up to half the vessel, as the cuttings take up a lot when rooting. In about ten days all have thrown out roots, and can then be potted off into 4in. pots. Three in a pot make a fine show and are a great improvement to any greenhouse when hanging down from the shelf among other plants in bloom.—T. S.

Checking Carrot Fly.

As the season approaches we must be prepared for the attack of such pests, and "prevention is always better than a cure." Get a pailful of sand, moisten with paraffin, and as soon as the seeds germinate sprinkle between the rows. Continue to do this weekly during May, June and July. Following this I am able to grow carrots which before were always victims of the carrot fly.—W. T.

Control of Woodlice in Glasshouses.

Woodlice are very destructive at this season of the year, when glasshouses are being filled with young seedlings and particularly so with tomatoes. An excellent control for this destructive pest is to mix 1lb. of commercial Paris green with 28lb. of dry bran. Broadcast this bait over the whole soil surface at the rate of about ½oz. to the square yard; in addition, sprinkle some on the staging, care being taken that it is not deposited on the plants. It is very important to broadcast after damping. Paris green being poisonous, a glove should always be used when handling the bait, which can be obtained ready made. It is also poisonous to live stock, so great care should be taken when being used in gardens, etc. For this purpose a light dressing of a fine flake pure commercial naphtalene is recommended.—H. S. P.

Onions Running to Seed.

Within the next few weeks autumn-sown onions should be planted out into beds previously prepared, advantage being taken of open weather when the soil is in good working order. The best varieties for autumn sowing are undoubtedly white Spaniah, Tripoli and Giant Rocca. In transplanting, care should be taken in lifting the young plants and in making them firm in their new position. Many growers, particularly on light soils in the south, are troubled by many of the plants running to seed in late summer, but this can be remedied to a large extent by planting only the medium size plants, leaving the strongest in the seed bed for drawing young. In this way the "bolter" can be practically eliminated from the crop.—W. M. C.

Hyacinths After Flowering.

It may not be generally known by those who grow the specially prepared hyacinths for flowering at Christmas that if the bulbs are slowly and carefully dried off they will flower again equally as early the next season if potted in August, and although the blooms are, of course, smaller than the first season, they are very useful for vases as cut flowers.—F. W. W.

How to Sow Shirley Poppies.

When sowing seeds of Shirley poppies and other annuals that are difficult to transplant, it is a good plan to space the ground as follows: Lines are scored on the soil, so that the surface is cut up into large squares; where the lines intersect, a pinch of seed is sown, and the resultant seedlings thinned out till one strong plant is left at each point of intersection. In this way the plants will be perfectly spaced without any trouble of transplanting. For poppies, the lines should be drawn about 1ft. apart; while, of course, for other annuals the distance apart will vary according to the variety concerned. Another advantage of this method of sowing is that the ground may be hoed and otherwise cultivated in a way that is impossible if the seeds are sown broadcast, with the result that the seedlings will be correspondingly more vigorous and healthy.—B. D.

GARDEN ODDMENTS

When and How to Apply Wood Ashes.

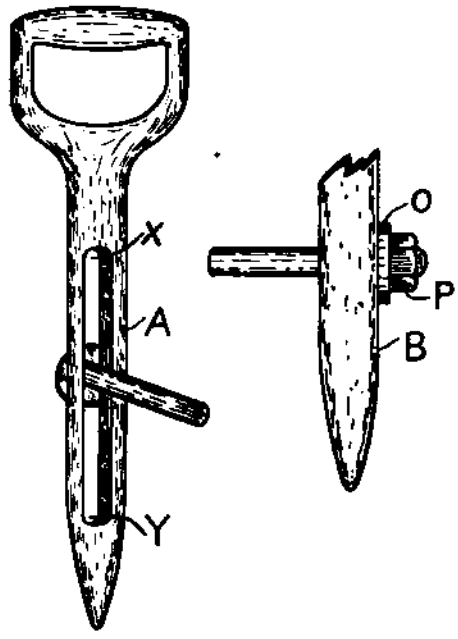
WOOD ashes or vegetable ash contains nearly one-tenth of its mass in the form of potash, and that potash is present in a highly soluble state; in other words, the potash in wood ashes is immediately dissolved in the presence of water, and it becomes available for plants practically at once. In addition to potash, which, note, is the fine powder of the ashes, there is in potash a varying amount of charcoal; this charcoal is one of the finest natural "soil sweeteners," and it absorbs ammonia which might otherwise be lost into the air, yielding it up later on to the rootlets of plants which twine round the lumps. It will be obvious from the above that wood ashes are likely to tell best if applied at cropping time or, later, to plants in growth. Separated into its two components charcoal and ash, the ideal plan would be to dress the former on the ground and fork it in lightly some weeks before, and the latter may be hoed in round the plants when growth is going ahead. The ashes may be mixed with all manures except ammonia salts, allowance being made for the fact that the potash is only one-tenth of the weight as a rule. We should apply ½lb. of wood ashes where 1 oz. sulphate of potash is usually given, and this is a very fair equivalent, taking all things into consideration. With ammonia manures wood ashes cause a loss of ammonia, and the applications should be made at not less than a fortnight's interval. Wood ashes are strongly caustic, hence they must not touch plants. Apply as a top-dressing round them and hoe in, or apply a few days in advance so that they become mellow in the soil. Wood ashes, applied alone or in mixture, should invariably be raked, hoed or forked into the ground, never left on top.—CLYDESDALE.

Manuring the Lawn in Spring.

GARDEN lawns, and particularly those in hard use during summer, may with every advantage receive manurial treatment this month. Growth is just commencing and the grass can take advantage of the help given. First of all I would point out that grass is a crop and that manures ought to be looked upon as a necessity. Poor, weedy, starved lawns are not a pleasure and are a reflection on the common sense of the gardener. Should the lawn not be required until May, there is still time to scatter over it a thin, a very thin, mulch of good sifted soil, sifted mould or sifted manure. Note that it must be *sifted* stuff, which gets washed down to the roots quickly. A very good plan also is to scatter peat moss litter broadcast, the rough and ready plan of the farmer, but which, I emphatically say, is a good one. A good dressing may be given. Five to seven days later it is swept roughly so that grass may not be rotted, and this is repeated. The stuff may lie a month, but, if the weather is rainy, less will do. Finally, the undissolved residue is swept up and added to the compost heap. I guarantee this to give new life to a jaded lawn, and it obviates the tedious work of sifting manure or leaf-mould. The above methods do not appeal to many who rely on the concentrated artificials. Of these, bone meal, a coarse purchase preferably, is fine for present application at some 3 oz. per yard or some 5–6lb. per rod. Fish guano is also very good, but not quite so lasting applied at the same rate. Where the lawn is one of very fine grasses one cannot give a better dressing than potassic-super or a mixture of superphosphates and sulphate of potash in the proportion 7 to 1, or 1 stone to 2lb. at 3–4 oz. per square yard. Of course, a lawn manure may be obtained and applied. Where daisies and other broad-leaved small weeds abound add to any dressing given ½ oz. to ¾ oz. crushed crude sulphate of iron and ½ oz. sulphate of ammonia (up to 1 oz.) per square yard. Manures which should not, as a general rule, be applied now are lime, soot, nitrogenous manures, basic slag or kainit. Bone manures, phosphates and super encourage clover. If clover abounds, use a mixture of fish guano and sulphate of ammonia in small dressings, applied monthly until May.—H. A.

A Useful Adjustable Dibber.

WHEN sowing such seeds as broad or kidney beans, peas, etc., by means of a dibber, the adjustable depth dibber indicated by A of the accompanying illustrations will be found most useful. The original straight dibber may easily be converted or, if it is undesirable to alter this, the dibber may be made



A USEFUL DIBBER.

from a broken spade or fork handle. First of all, drill a half-inch hole at points X and Y, and cut out the slot by means of a keyhole saw. Obtain a piece of ⅜-in. rod about 5ins. long, and screwed for about 2ins. one end to take a ⅜-in. nut. The rod is held in the slot by means of the washer O and nut P, as indicated by view B. The rod is fixed in any desired position along the slot, and set by means of the nut, so that all the seeds will be planted at a uniform depth. The nut need not be tightened up by a spanner, since the rod will keep in position by screwing up firmly with the thumb and finger.—W. J. SAUNDERS.

Formalin Spraying for Rose Diseases.

THE control of several diseases which infest the garden rose is very difficult, but during late years some success has attended the use of formaldehyde or, as it can easily be purchased almost anywhere, formalin. This liquid is a powerful disinfectant. It must be diluted with water first, of course, but as it mixes readily with the water there is not the slightest difficulty attending its use. At the present time, when rose bushes are dormant, it can be used at a higher concentration. I generally apply the liquid to all roses at the rate of ¼ pint in a large can (about 2 gallons) of water. A month later I use it again at half the above rate, roughly two tablespoonfuls to a gallon, and immediately after pruning early in April I give a third and last dose. In all cases the fungicide is applied as a coarse spray in such a way as thoroughly to wet the whole of the bush and the ground under it. It is essential, note, that the ground be treated at the same time. Certain growers continue the formalin treatment right on into the summer, but I do not advocate this, except in very bad cases where the rose must be saved, even at the expense of foliage and blossom. Should the disease reappear—I do not give formalin as a "cure-all," though it is a first-class "preventive"—I urge two further sprayings in September and October, at least one of them being given before the leaves fall. Careful and thorough treatment in spring, nevertheless, is a long step towards immunity for the season.—A.

Seedling Protection.

ALL kinds of things menace the well being of the tiny seedling from the moment it appears above the ground. Heavy rain will often do a lot of harm to the little plants, dashing them to the ground, so that even if they are not destroyed they receive a serious check. Protection for the seedlings may be found in arching them over with a few twigs or protecting them with wire netting. Serious damage by frost is often prevented by the use of small branches of fir, gorse or broom. These may usefully be laid over the seedlings at night in such a way that the plants are not actually pressed down. Inverted boxes or sheets of newspaper pegged at the corners may also be employed with advantage. No covering should be left too long over the plants or permitted to press them down. Often in the early spring more damage arises to the seedlings from the effects of cold winds than from actual frost. Here a 6in. board held on edge by means of pegs and placed on the windward side will check the rush of biting air. If a board cannot be obtained, soil may be heaped up to serve a like purpose. Out of doors strong sunshine does little harm to seedlings, but inside a glass structure it may do a lot of damage in a short while. Sheets of paper or pieces of cloth over the plants may be used to provide shade, although it is better if possible to have blinds or some material to cover the glass during the sunny hours. Sparrows and some other birds seem to take much delight in pecking at seedlings, and they will often do a lot of damage. A network of black thread over the plants will keep the birds away almost as well as anything. Wire netting is also good, although here the mesh should be small, otherwise the birds will pass right through the openings. The ravages of slugs, insects and other pests are often considerable where seedlings are concerned. Here there is nothing better to use than soot which has been allowed to weather for a few weeks. This may be scattered freely over the little plants, but it is most important to remember that soot should never be used straight from the chimney, as it then has a burning action which will prove very harmful to young leaves. The writer has found that where slugs are concerned it really pays to provide a counter attraction to the plants in the form of orange peel. Slugs seem to have a perfect passion for the white inner portion of the rind, and if a number of pieces of fresh peel are placed near seedlings the plants will be severely left alone.—E.

THE GARDEN

VOL. XCI.—No. 2883. · MARCH 5, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

The Annual Border.

SPACES in herbaceous borders, odd corners and bare patches are all filled with annuals, but the full glory of an annual border is seldom seen. Given the desire to make much of annuals, certain requirements must be fulfilled. A sunny position should be chosen for the border, which must be neither too wide nor too long; excessive width leads to thin effects, while too much length may produce monotony. The soil should be light, rich and well prepared; a good manuring every other year gives the right degree of richness. The final requirement is a plan. Because the colours of annuals are bright and sometimes crude, arrangement is all-important. The grouping of each variety should be bold, and hard lines should be avoided. It is always best to grow a limited number of different kinds of annuals in fairly large quantities.

Many considerations must govern the choice of seeds. Colour, height, manner of growth and flowering-time are all important points. Height is particularly important, sudden jumps from dwarf plants 4ins. high to plants of 2ft. or more being ugly and unnecessary. If a brief but glorious blaze of colour is wanted, annuals which flower simultaneously must be chosen, but it is more usual to plan for as long a flowering season as possible. In the nature of things, annuals are essentially summer flowers, and there can be but little colour in the annual border until the middle of June.

A list of the flowers suitable for this border is given below: Ageratum mexicanum, half-hardy; Calendula officinalis (marigold), hardy; clarkias, hardy; Coreopsis tinctoria, hardy; Cosmea bipinnatus, half-hardy; Delphinium Ajacis (larkspur), hardy; godetias, hardy; Helichrysum bracteatum (everlasting flower), half-hardy; Limnanthes Douglasii, hardy; Nicotiana affinis (tobacco plant), hardy; Nigella Damascena (love-in-a-mist), hardy; stocks ten-week, half-hardy; night-flowering stock, hardy; Papaver Somniferum (opium poppy), hardy; mignonette, hardy.

The Gardens at Olympia.

VISITORS to the Ideal Home Exhibition, which opened at Olympia on Tuesday last, should not fail to inspect the gardens laid out in the Annexe. Every year there is much to interest the keen amateur gardener in these exhibits, and on this occasion the gardens are particularly bright and attractive with many new features. More and more every year the wealth of spring-flowering subjects which exist for spring decoration of the garden is brought home to one by a look round these exhibits. There is no need for the garden to look bare in these early months if a few early flowering shrubs and bulbous plants are grown. In addition, the amateur will obtain many fresh ideas on the designing of a garden with due regard to small space and the production of a fine floral display over the greater part of the year. The many formal and rock gardens hold many educational features as well as being full of beauty. A full description of the exhibits will appear in one of our near issues. Meantime, we would urge all who can to visit the exhibition and see the gardens for themselves.

New Plant Introductions.

AT the last meeting of the Botanical Society of Edinburgh, Mr. George Forrest gave a lecture on his recent botanical exploration in Yunnan during 1924–25. Owing to the disturbed state of the country, the exploration was more or less confined to the areas adjoining the north-eastern Burma frontier. The district had been previously visited by the lecturer and also by Cox and Farrer, but the lecturer's recent exploration has added very considerably to our knowledge of the rich flora of the district, particularly in the genera of magnolia and rhododendron. The area, although politically included in China, belongs geographically to Burma and the basin of the Irrawaddy. The hills are covered with dense coniferous forests, but hardwoods such as castanopsis, quercus, litsea and lindera are also abundant. One of the special features of these forests is the large number of representatives of the genera magnolia, manglietia and michelia. Of manglietia several new and little-known species were discovered, prominent among them being one, provisionally referred to as M. Hookeri, and another, for which the name M. Forrestii is proposed, both magnificent, wide-spread forest trees with abundant large foliage and beautiful magnolia-like flowers. Of rhododendron many dwarf species were found, the most striking being Rh. aperantum in its many coloured forms. This is a dwarf, semi-prostrate plant from 6–18ins. in height, forming mats as much as 12ft. in diameter, and clothing rocky alpine slopes in acres. In foliage there is little variation, but the flowers range from pure white through yellow and pink to the deepest shade of crimson. The large flowers, six to ten together, form compact trusses. In the lecturer's opinion, this is one of the best of the genus for rockwork from the horticultural standpoint. Among many of the larger tree rhododendrons were numerous species belonging to the Irroratum series, symmetrically formed shrubs from 6ft. to 20ft. high, with handsome light-coloured foliage and great variety in flower.

Of herbaceous plants of undoubted horticultural value many species were secured. Among these was a new species of nomocharis, N. Georgei, with large purple-blue flowers, a plant of the open Alps found growing on grassy slopes on a granite soil with good drainage. Mention should be made also of four new species of primula, two belonging to the Davidii section, one of the petiolaris section—all three having deep purplish flowers—and one of the candelabra section, with flowers yellow, flushed rose at the margins, a specially fine plant. These primulas are woodland plants of deep humus soil.

The lecturer also gave an outline of the peculiar flora of the mountain region in the early spring or dry season, referring to such species as Primula alta, a beautiful plant of the denticulata section; Osbeckia yunnanensis, a handsome half-shrubby plant with rose-coloured flowers, belonging to the melastomaceæ. Mention was made also of fine species of iris and gentian, several of the latter genus being novelties.

This Week's Work

Sow hardy annuals.

Prick off seedlings of annuals and vegetables now growing in pots or boxes in the greenhouse.

Sow spinach, cabbages, turnips, carrots, peas and broad beans in the kitchen garden.

Transplant autumn-sown onions and sow thinly the main crop of onions on a firm bed of light soil.

Plant out sprouted potatoes.

Apply worm-killer to your lawn.

Make a sowing of celery in boxes placed in a warm greenhouse.

Lightly fork over your herbaceous border.

The result and solution of our Crossword Puzzle competition will be found on page xvii.

Digitized by Google

TRANSFORMING A GARDEN

With Suggested Innovations

MANY people are inclined to believe that their particular garden is everything that can be desired, and are quite content to work it year after year in the same old style. Somehow they get accustomed to the various formal beds and borders with invariably the same quantity and variety of plants each successive season. The straight, uninteresting paths are regravelled at regular periods and, apart from the inclemency of our English summers, each season repeats itself. These contented folk have no incentive to further their gardening propensities in any way.

Others there are, however, who believe with Cowper that "Variety is the very spice of life" and are never happier than when making or planning alterations. The ever-increasing popularity of gardening as a hobby affords such a wide range for originality that the resourceful garden lover need never have an idle moment at any period of the year.

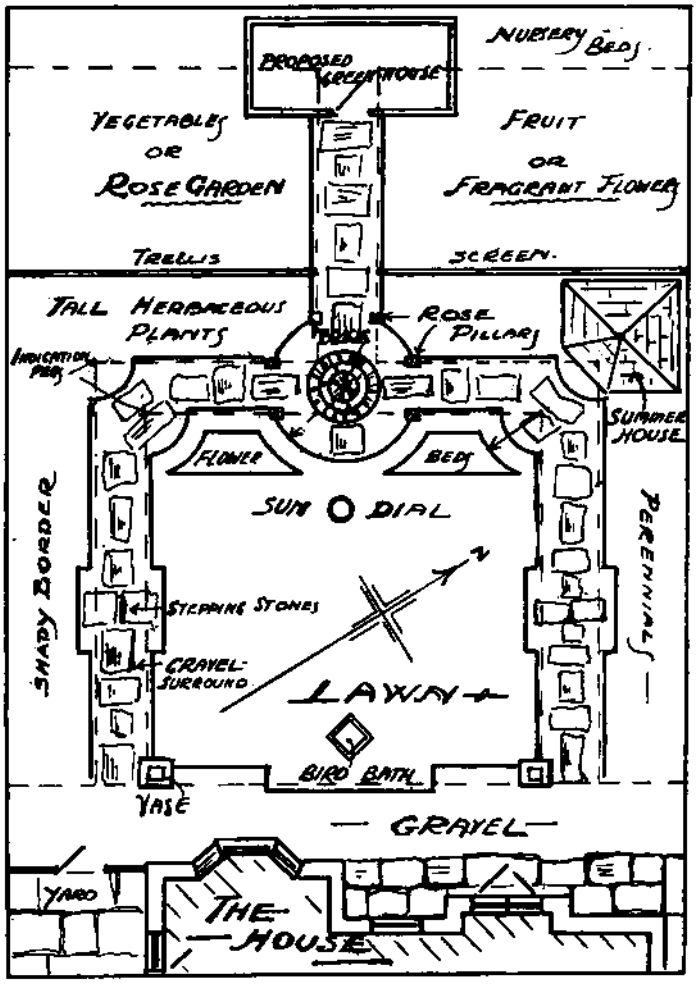
The accompanying scheme now under consideration deals with various suggestions for innovations in a garden already in existence. Certain alterations have been suggested for the improvement of the original plan, the old scheme being indicated by dotted lines, the thick black lines representing the altered scheme. It will readily be seen at a glance that the arrangement is greatly enhanced by the various changes, while the general constructive principles have not been unduly altered.

The straight gravel path, just wide enough for our friends to walk in single file to inspect our newest rose trees, gets very monotonous, but introduce a brick or stone portion enlarged somewhat about the centre where half a dozen people can stand to discuss the various merits of a certain new introduction, this little suggestion alone adds variety in several ways, not only in the area of the walking space alone, but also in the adjacent borders, which are recessed in consequence, giving a far better opportunity for the arrangement of a colour scheme than hitherto. Should the owner wish to improve still further, a summer-house could be erected where seclusion is most needed. On the scheme in question one having five sides would perhaps be the most suitable for the sunny corner site, the two largest sides acting as a wind screen. Whatever the situation or design, a garden house is bound to find favour with both old and young alike. Additional comfort can readily be secured by providing wind shutters of glass or a substitute for all the apertures at the sides. It only remains now to enclose the doorway and the summer-house is converted into a roomy store for garden chairs and other equipment not required during the winter months.

Even a niche made in an existing hedge or a recess in the herbaceous border for the reception of an arbour where roses, clematis or honeysuckle will make a shady bower under which a white garden seat can be placed. A break made in the path as previously suggested with a few stone slabs laid down in the vicinity of the seat will entice the book lover and those in need of rest to this favourable little retreat.

The square lawn may be very beautiful and the restfulness of the green sward may be to some all that is desired, while others are anxious to get more colour and tone into its surroundings. There is, however, a wide range for such innovations in conjunction with the lawn. A homely bird bath is suggested near to the house, and all bird lovers will be sure to derive much pleasure from this feature alone when they see dozens of birds using it daily for a free bath and refreshment. A sundial is also indicated at the opposite side of the lawn, the introduction of which adds both charm and beauty to the setting. Two ornamental flower-beds have been inserted on either side of the sundial, the curves of which should be symmetrical with the proposed new scheme for the paths. An indication mark in the form of a piece of small iron barrel should be inserted as a permanent centre for striking the curves; this facilitates matters wonderfully when trimming the edges of these curved portions. A peg is pushed into the barrel and by using the knife fixed to the garden line accuracy is assured for all time.

Rose pillars are suggested at the crossways, and if something really permanent is desired, one cannot do better than to purchase ready made some reinforced concrete pillars. These require no protective coating, the natural colour of the material, combined with a touch from Nature's hand, blends well with the green foliage of the ramblers which will very soon clothe them. The initial cost of such pillars is the only one, and they are worthy of consideration. In the centre of the pillar walk some unique design in brick would be very appropriate, and could be bordered on either side by the gravel which previously existed. The same idea could be used for the other paths if a change is needed, excepting that perhaps concrete slabs or rectangular paving could be used as the centre walk, utilising the original gravel as before mentioned for the surrounds. This method of path making is quite novel, and it reduces the laborious weeding to a minimum and ensures a dry walk at all times. Brick or other suitable vases could be introduced at the corners to accentuate the design. The wide herbaceous borders which run across the garden on either side are shown considerably farther back than before, and a trellis screen is indicated as a dividing line. But one will be well compensated by being able to introduce into those borders many of the taller perennials, and here comes a splendid chance for a colour scheme, which, if well arranged, should look exceedingly picturesque from the house.



If the garden is of moderate dimensions and a change is desired where fruit trees and vegetables are now planted, a piece could be reserved and suitably enclosed for some special purpose, such as a rose garden or an iris garden. It is best, however, to keep the characteristic features quite distinct. If all the characteristic points of a garden are seen at a first glance, it is quite obvious that there will be no cause for anticipation, and there is bound to be loss of interest in consequence.

It will be seen that the vista from the principal rooms of the house is in no way impeded by obstacles, but it would be incomplete without a central feature of some kind at the extreme end. It is suggested here as a small greenhouse with the door facing the central path, but this must depend on the tastes and requirements of the owner in question. The tea house could well be placed here or even a comfortable seat if the surroundings were considered as ideal. For instance, a seat or tea house in the vicinity of a rose garden or a fragrant garden would be very charming, but if the same plot were devoted to vegetable growing one could not be expected to recline in a deck chair or hammock among decaying cabbage leaves or a smouldering rubbish fire. So it is essential first to decide on the nature of these surroundings before such features are installed.

In making innovations of any kind in a garden already in existence, it is a wise precaution to study the whole thing carefully from various aspects and points of view.

A garden is intended as a place of rest and recreation, and it is only by creating these beauty spots that welds the home and garden into one.

GEO. W. HALL.

NOTES ON THE FLOWER GARDEN

Herbaceous Phloxes.

INCREASED interest has been shown in recent years in phloxes, which bring colour into, and make our gardens gay in the autumn. Given right conditions of soil, one may plant clumps in March and be rewarded with flowers in September. Herbaceous phloxes delight in a deep, rich soil, as for example, loam to which has been added good rotted stable dung. If the soil where it is proposed to plant phloxes is very heavy, then it should be lightened by incorporating road grit and leaves along with the manure. In planting clumps in March, let the ground be well dug, and if it is possible to chose the position, avoid a south aspect and plant on a north or west border, where they can have the benefit of partial shade. Should the season prove a dry one, it will help the plants very considerably if they can be given a mulch of old manure as the warmer weather approaches. Staking may be found needful in exposed localities, and abundance of water must be given in a time of drought.

Propagation.—Phloxes are sometimes increased by a rough and ready method of division, by running a spade through the clumps in late autumn or spring. It is not to be recommended, as it is not only wasteful, but often injures the clumps. The better plan is to lift the clumps, then with a blunt knife work carefully between the shoots until the roots are severed.

Another method of propagation is to take a few of the many cuttings which show at the base of the plants in July. Cut them at a joint about 3ins. or so long, insert them in pots of sandy soil and place them in a cold frame, where it will be necessary to afford shade until rooting has taken place.

It is never a good plan to allow phloxes to continue undisturbed for years, but every three years they should be taken up and divided. It is only by these means that one is able to keep up the quality of the flowers. Huge clumps mean that the centre shoots cannot possibly get the nutriment they need, and consequently in a dry period, they wilt away, or, if they do flower, the panicles are insignificant. It is the clump with about a dozen healthy shoots that yields the finest display, and beyond this there is always risk. Let no one who omitted to procure phloxes last autumn think it is too late to trouble with them, as, given attention in the manner suggested, next autumn will bring the flowering spikes.

There is a wonderful array of colour in present day selections, from purest white to rosy pink, from lilac to deep purple, with rich salmon and carmine, and softer shades.—F. W.

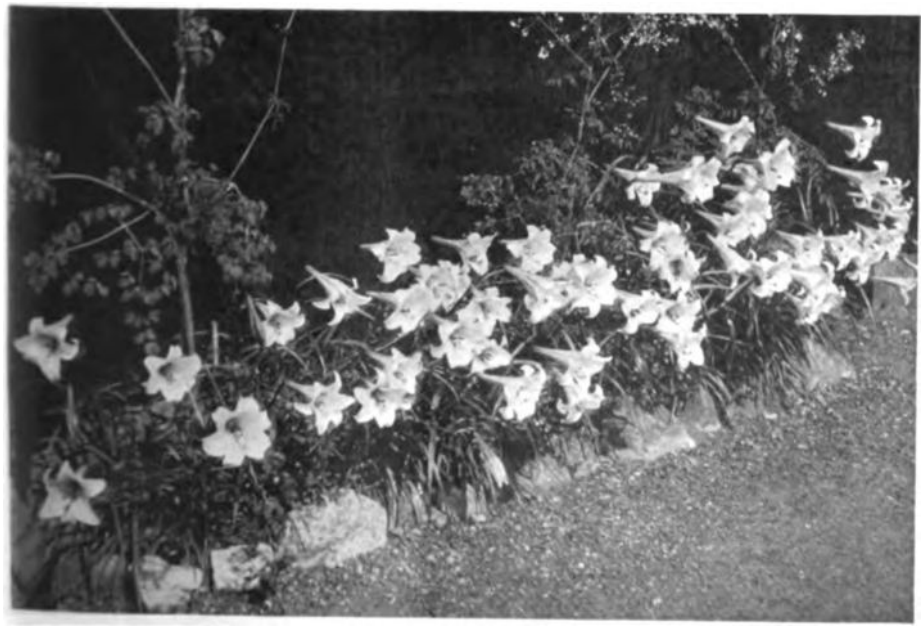
Lilium philippinense formosanum Price's Variety.

THIS beautiful lily was introduced to cultivation by Mr. W. R. Price of Pen Moel, Chepstow, Mon., in 1912, being collected by him on the Morrison Mountain, Formosa. Although it is admitted to be one of the finest of trumpet lilies, it is still very rare in gardens in this country, especially out in the open, and is looked upon by a few cultivators as being only fit for pot work. I am certain that the chief cause of their failures out of doors is the choice of the wrong position and soil. Cutting north and east winds do a lot of damage to the young growth, and often cause disease in course of time. To ensure success choose the position to avoid these evils. Interspersing the lilies with a few low-growing shrubs will give the necessary shelter and more natural effect out in the open.

If the natural soil is of a heavy nature, take it out to a depth of 2½ft. at least, placing a foot or so of stones or clinkers to ensure thorough drainage, and then add two parts of turfy loam, one of leaf-soil and one of coarse sand thoroughly mixed.

This charming lily is best propagated from seed, which can easily be flowered in about twelve months. Sow the seed in the spring in light soil in pans or boxes and place in a gentle heat. Germination will then take place in a few weeks, or seed may be sown in a bed of prepared soil in a cold frame. When seedlings are from four to six months old plant out into prepared beds in small clumps; this is much better than trying to divide them singly.

The flowers are white flushed with pink outside and have a refined appearance. The trumpet is about 6ins. in length, tapering off very narrow at the base on wiry stems 1ft. to 2ft. in height, and the narrow grass-like foliage is one of the distinct characters of this most desirable lily.—J. ADAMSON, *Moniaive.*



A BORDER OF LILIUM PHILIPPINENSE FORMOSANUM PRICE'S VARIETY, ONE OF THE FINEST OF TRUMPET LILIES.

A First-Rate Shrub.

ALTHOUGH our gardens have been enriched by so many fine introductions during the last quarter of a century, the subject of this note must always claim a prominent place among the choicest of them. In a sense, O. Delavayi is unique, for it is quite unlike the rest of its genus and "streets ahead" of all of them in garden merit. In its native Yunnan it is said to reach a height of 6ft., but the specimens one sees in this country are more often under 3ft. with rather a spreading, lateral habit. The branches are rigid and few, and the leathery, dark green, glossy leaves are oval, or ovate, in shape, minutely toothed, and not more than an inch long and half as wide. The flowers appear in spring in the shape of waxen white trumpets in small axillary and terminal clusters. Their superficial resemblance to the blossom of a daphne is enhanced by their delicious perfume. These blooms are said to be followed by sloe black fruits, but these have not yet been yielded by my specimen, though it blossoms with commendable regularity every year.

OSMANTHUS DELAVAYI WITH ITS WHITE TRUMPET FLOWERS.

A fine shrub for present planting.

O. Delavayi, which is evergreen, is quite hardy and not at all difficult. It seems to flourish in an average warm loam with full exposure, but as it blooms in April or May some little shelter from the morning sun may often be helpful in the event of late frosts. I have O. Delavayi in an open part of the woodland among other dwarf shrubs, but it makes a good rock garden subject. Though I have not attempted propagation, it is said to strike readily from cuttings made in late July and provided with gentle bottom heat.—A. T. JOHNSON.

VIOLAS FOR BEDDING

No matter what they are called, violas rank high among the favourite flowers for bedding. They are of easy culture and give a pleasant variety of colour to any bedding scheme. They are especially suitable for edgings to rose beds.

HERE is a list of up-to-date varieties, easily grown, hardy, very free flowering and having a tufty habit. They are readily propagated from cuttings, and old plants may be divided after the second season. They like a semi-shaded situation, but they can be grown in almost any position if the roots can find plenty of moisture and plant food. All faded flowers and seed vessels should be removed during the flowering period and a continuous display of bloom is then assured.

There is a wide selection of varieties, but the following should give general satisfaction.

Whites.—The best white is undoubtedly Swan. This has an excellent habit and it is very free-flowering. The flowers are pure white in dry, sunny weather and they are perfectly rayless. The eye is a rich orange and is very neat. Another popular white is Seagull, but the eye is a little paler and not so conspicuous. A newer introduction is Lady Tennyson, that bears a slightly larger flower than Swan or Seagull, but it is not so free flowering.

Creams.—Lady Knox is one of the best creams. It bears a well sized bloom of good form. Cream King and the larger flowered Master Bankes are both good varieties, although the latter is nearer a lemon yellow.

Yellows.—Here we have a wide choice. The well known Moseley Perfection is one of the best of the deep yellows. It gives a large bloom, but on account of its free-flowering characteristics it makes a bold display. This variety is very good when grown as a two year old, and it winters well in most districts. Smaller flowered varieties in this section are Kingcup, Klondyke, Bullion, Walter Welsh, Redbraes Yellow, Mrs. C. B. Douglas, George Palmer and Tangerine. All these have a dwarf, tufty habit and are very floriferous.

Purples.—Royal Purple is the best in this colour, being an improvement on the old variety, Councillor Waters. A new purple self of good habit is Purple Queen, but this is not very well known yet. Jubilee is a splendid bedder.

Mauve and Lavender Shades.—Maggie Mott is a popular soft mauve. It is a good grower and free flowering. The colour varies a little with the weather, but when seen at its best it is very pretty. A soft mauve with a slight touch of rose in its composition is John Quarton. The early boooms of this variety are very well coloured, but it pales a little as the season advances. Mauve Queen is a distinct mauve self, and Mauve Radiance has a silky finish. Fred Williams is a bluish mauve of strong growth and good habit and Bridal Morn is somewhat similar.

Blues.—The best pale blue is W. H. Woodgate. It is not a very vigorous grower and in some districts it needs good cultivation to make strong plants. A deep blue can be chosen from either Royal Scot or Admiral of the Blues. Archie Grant is an indigo-blue.

The Picotee-Edged Varieties.—These are very pretty and include several choice varieties. Mrs. J. Scalley, white with a pale blue edge; Mrs. J. Terris, white with deep blue edge; and Waverley, white, edged with medium blue, are all capable of giving well sized blooms and the plants have a good habit. James Pilling, white edged with heliotrope, is a very free-flowering kind, with a short, cobby habit; and A. S. Frater, creamy white edged with bluish lavender, also makes a capital bedder. Mrs. Chichester is a well known kind, with an edge of purplish mauve and a suffusion of the same colour over the petal, especially in wet weather. It is a very useful bedder and quite hardy. Dunbryan, white, edged and suffused with soft heliotrope, is a very dainty variety, and the bolder coloured Pride of Darras, white with a deep band of purple, is an improved form of the old favourite, Gladys Finlay.

Bronzes and Other Shades.—The bronzes need a shaded position to be seen at their best, as they lose their colour in full sunshine. Redbraes Bronze, Bronze Kintore and Bronze King are three good varieties. Cyril Bell has a rich golden centre with a broad band of mahogany. It is a very distinct sort. Mrs. Marrison is a dark mahogany striped with pink and rose, and the flower has a rich velvety texture.

NORMAN LAMBERT.

AN ATTRACTIVE BED OF VIOLAS MADE WITH VARIETIES MAGGIE MOTT AND WHITE SWAN.

Both are good sorts for growing in the small garden.

ASTILBES FOR MOIST BORDERS

SOME gardens are noted for their well drained light sandy soils, while in others conditions are just the reverse. Here the ground is heavy, and inclined to be moist the year round. In such a garden it is hopeless to try to grow many plants which enjoy plenty of drainage, but in such districts the astilbes would thrive, and be a joy to the owner from July to September. To some these desirable subjects may be better known under the name spiræa, and the general habit is somewhat similar to the old Spiræa japonica, a species largely employed for forcing purposes some years ago.

For the damp or moist border the astilbes are ideal; while for the bog by the rock garden, or near the edges of streams, they would revel either in full sunshine or shade.

Two noteworthy plants were introduced from China some years ago, *viz.*, A. Davidii and A. grandis. The former produces tall slender spikes of rosy purple flowers, and is superseded to a great extent by its progeny. The latter, A. grandis, is a noble plant 4ft. to 5ft. high when well grown, with spikes of pure white flowers, and I have seen examples growing in the bog with upwards of twenty-five scapes. This is rather large for the ordinary border, but the same complaint cannot be levied against the hybrids, a few of which are enumerated below. They are known as A. Arendsii hybrids, and constitute a race of which any raiser might feel proud.

First and foremost is Venus, a fine deep pink, its lovely plumes, often 3ft. high, being most attractive. Salmon Queen is sometimes slightly taller than Venus, and somewhat resembles A. Davidii, but the spikes are looser and more elegant, while the colour is a charming salmon pink. Pink Pearl is a warm delicate pink, and is noteworthy for the elegant arrangement of the flowers and the spike as a whole. Ceres is remarkable for the soft feathery panicles of rosy lilac flowers; and Queen Alexandra is a deep pink. This is one of the earlier varieties, and its delightful inflorescence still warrants it a place in the first half-dozen.

Amethyst is a deep violet purple, and Gloria is a very fine deep rose pink, quite a superb variety. All are of easy culture, and, when we remember that they are all showy and beautiful flowers, they can only be included under the heading of capital garden plants. They make excellent pot subjects for the cool greenhouse, where they can be had in bloom during April and afterwards utilised for the border or bog garden. Now is a good time to purchase plants, and they should be planted directly they are received. It has been stated above that a damp situation is preferable, but an enthusiastic amateur will overcome the difficulty of drier surroundings by affording the plants a mulch of partly decayed manure, and an occasional watering during the growing period. The hybrids and varieties quoted above vary in height from 3ft. to 4ft. when in bloom, and when once planted are best left alone for three or four years. Old clumps which have exhausted the soil should now be lifted, divided, and either replanted on a fresh site, or the old rooting medium enriched with a liberal dressing of decayed cow manure. Hop manure is a good substitute, while a sprinkling of bone-meal is always beneficial.

T. W. B.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

THE SUN ROSES.

Helianthemum (Sun Rose). THIS is a very charming and indispensable plant for the rock garden or for positions in the garden where it can trail and its blossoms be seen to full advantage. It is a low, prostrate, shrubby perennial that loves a sandy soil and the sunniest place which can be assigned it. It commences to bloom in May, and continues for weeks, the output of flowers being very numerous in the course of a season. Blossoms are both single and double and in a variety of colour. Propagation is by cuttings dibbled in pots of sandy soil in July. These should be placed in a shady frame.

Funkias (Plantain Lilies). HARDY, herbaceous Japanese plants, noted for their lily-like flowers, but valued more for the beauty of foliage, which is striped and margined in white and yellow in some of the varieties, while others are conspicuous for broad noble leaves. They are plants so little affected by severe winters that one may leave the question of protection almost out of account. Funkias are among the very best subjects one can take in hand for planting in a shady or half-shady position in the garden—as, for instance, under trees, or where the sun falls but little. They will grow in almost any soil provided it is deep and well drained; but to see them at their happiest, a generous soil in which old manure and leaves have been worked is best for them. Their time of beauty is in May and June, when foliage is freshest, though flowers continue most of the summer. Flowers are fragrant. Planting time is autumn or spring, and the latter should see any dividing taken in hand—the best way to increase the stock. In planting, 2ft. apart should be the minimum.

PLANTAIN LILIES ARE EXCELLENT FOR A HALF SHADY BORDER.

THE CONEFLOWERS.

Rudbeckia (Coneflower). ALMOST like small sunflowers are the blossoms of rudbeckias, making them of service to the grower of flowers for cutting. They are hardy perennials, doing well on sunny or partially shaded borders, and will thrive in a loamy soil of moderate richness. They should be planted in autumn if possible, though March planting will serve, provided they are helped with mulchings of old manure and copious supplies of water in a dry period. Rudbeckias are among the first plants to feel ill effects of drought. They need not be taken up and divided every two or three years, and can be raised from seed sown out of doors in any light soil in April or May, or from division of roots in autumn. They bloom mostly in August and September, have greenish or black zones, and are effective for table decoration if the stems are first bruised to allow the water to percolate, varying in height from 3ft. to 7ft. Plants should have plenty of room between others if located in back rows.

The Herbaceous Peony. FEW hardy plants in our time have made greater strides in favour than the herbaceous peony. Some of the old ideas concerning its culture—like old varieties—are discarded, as for example, the shifting of plants, about which it used to be told that "it took years to get over it." To-day we know this is a fallacy, and that if clumps are planted in good time in October, some few at least will throw up flowers the following summer and all the succeeding year. Blooming for the most part in May and June, they give glorious blossoms in both single and double forms, in a variety of colour, that are acknowledged to be superb for cutting and for home decoration. Averaging about 3ft. in height, peonies should be planted where they will not be hampered for room and where it will be unnecessary to disturb them too frequently. Soil for them should be made up of loam, or good garden soil, cow or horse dung, vegetable refuse which has decayed and plenty of grit or sand worked in. The place should be prepared for the plants some time in advance by well trenching the ground, as upon this, much of their after success depends. Should a dry season follow the first planting, it is essential that they should be well supplied with water. A partially shaded position is very suitable for them. Propagation is by division of the roots in October or spring, an operation that needs care in sorting out the eyes for transplanting—but, speaking generally, peonies should not be often divided, if they are doing well. Of recent years they have come into prominence as plants in suburban gardens.

THE BUSY MAN'S PAGE

March Reminders.

ASPARAGUS may be planted; if produce is wanted at the end of the first year, three or four year old sets must be secured.

The main crop of broad beans may now be sown.

Make a sowing of cabbages for late summer use.

Carrots may be sown for a general crop.

Transplant the seedling cauliflowers in boxes to 3ins. apart when they have made their second pair of leaves. Give plenty of air, but avoid over-watering.

Cucumbers can be sown in heat, one seed being placed in the centre of each pot.

Celery can be transplanted in the same manner as cauliflowers.

Leeks can be sown either in a box or in the open ground.

Onion seedlings that are growing under glass should be thinned or transplanted to prevent their being drawn.

Parsnips can be sown in rows, but this crop must never be grown on freshly manured land.

Peas may be sown for succession.

Potatoes may be planted, the late sorts being put in from the middle of the month.

In warm spots sow all kinds of salads.

Spinach may be sown, and any previous sowings should be carefully thinned out.

Seedling tomatoes must be watched to see that they do not become overcrowded. When the first pair of rough leaves is formed, transplant.

Sowings of early turnips may be made.

Sow seeds of vegetable marrows, putting just one in the centre of a 3in. pot. Place in a greenhouse or hot-bed.

Do not forget that winter greens, like broccoli, Brussels sprouts, kale and savoys will be required next autumn, winter and spring, and, to secure these, sowings must now be made.

How to Treat Border Chrysanthemums

MANY border varieties have been killed or damaged during the winter, and in numerous instances the surviving roots with their suckers will, if left in the border, be very late in making new growths. As time is valuable and amateurs wish to have a good display of flowers as early as possible and for a lengthened period, no time should be lost now in getting up all the old roots carefully dividing them and then planting the separate parts in good compost in a cold frame or in boxes in one. The ideal compost is one made up of loam and leaf-soil in equal proportions, with a free addition of coarse sand. All old border soil should be shaken off the roots and the latter then neatly planted, rather close together, in the new soil. Apply water at once through a rose watering-can, close the frame and, with the exception of ventilation a little each fine morning, keep the frame closed for a fortnight or so. Afterwards admit air, at first a little, then in abundance. Splendid little clumps will be available for replanting late in May. In the meantime, dig and manure the border soil.

Sweet Peas in Tubs.

READERS who have small gardens and others who wish to decorate porches or to beautify corners near the front door, may easily grow sweet peas in tubs or deep boxes. Such receptacles may be obtained now; the grocer may be able to supply suitable ones cheaply, but care must be taken to see that they are firmly nailed up; thereafter give them two coats of green paint outside and at least round the rim inside. They should be a foot in diameter at the top and a like depth, at least. At this time sow sweet pea seeds in small pots, say four in a 4in. pot and grow the plants on in a frame until May; readers who have no garden at all may, of course, purchase plants in May. In April bore a few drainage holes in the bottom of the tub or box, fill in a layer of ashes or stones, lay a piece of turf upside down on top and fill in with loam, to which has been added, if possible, a little manure and leaf-mould—not too much, however. In May knock out the plants with ball of soil intact and plant in the tub; put in three plants in a large pot, or twelve plants in a tub

SWEET PEAS IN TUBS ARE EASILY GROWN AND MOST DECORATIVE.

a foot across. Erect a framework of canes, branches or netting, tie in any straggling shoots, water daily and feed when blooms begin to come out plentifully. Sweet peas are easily grown in this way and they make a lovely show.—LANARKSHIRE.

The Value of Catch Cropping.

THE amount of produce secured from a garden may be very much increased by a system of inter-cropping. When setting out maincrops enough space is allowed between them so that the plants may fully expand. In this way, at the start, the crop occupies far more space than is really justified on land that has naturally been brought up to a high state of efficiency. By adopting a proper system of catch-cropping, it is easy to raise some quick-growing vegetable which can be cleared before the space is required by the main crop.

Here are a few helpful suggestions in the matter of intercropping:

As a rule, the space allowed between the rows of peas is from 3ft. to 6ft. Here there will be plenty of room for such plants as spinach, lettuce, radish and turnip. In a space of 6ft. it would be easy to grow three rows of turnips at a foot apart, the outer ones being 2ft. from the peas. Between the peas and the turnips, radishes might well be sown. Spinach might also be sown in between runner beans where the seeds were set in pairs about 12ins. apart. Lettuce and spinach can be grown down the centre of the ridge between the celery trenches or lines of leeks. Brussels sprouts are a long time in occupation of the ground, and, while the plants are still young, lettuce, spinach, etc., might well be used as catch crops.

Top Dressing Alpines.

A VERY common cause of loss among alpine plants is owing to the height at which they grow out of the ground or because the soil about them has been washed away by rain. It will be found of great assistance to go over the plants regularly and to top-dress any which may stand in need of it. This should be done once a year at least, in the spring, and if the same practice is carried out in the fall so much the better. As a general rule, it may be said that all plants forming a kind of neck or stem which rises above the soil in course of time should be top-dressed so as to bring the earth to a level with the base of the lower leaves. When the plants have grown too high to be treated satisfactorily by the simple adding of soil, they should be lifted and planted more deeply. Many cushion-like plants will be all the better for having some fresh soil worked in among the rosettes of the leaves. A suitable top-dressing for alpines is a mixture of loam, leaf-soil (or peat) and sand. After the application it is a good plan to water the plants once or twice.

Soil and Seed Sowing.

MANY gardeners, and especially those to be classed as beginners, are apt to follow too implicitly the instructions which are printed on the packets of seeds. This they do without giving a thought to special circumstances, and, as a result, they not infrequently suffer disappointment. For instance, the seed packet says that certain seeds should be sown in March, and the novice, accepting this as a rule, gives no thought to the conditions of soil and weather. It cannot be too emphatically stated that to sow seeds in cold, wet soil, especially in the case of the smaller sorts, is a certain way of courting failure. It is far more important that the sowing should be done when the ground is dry and friable, rather than on any particular week or even month.

How Crops are Sown or Planted.

QUITE a lot of vegetables are sown or planted in the positions where they are to mature. The most important of these are beans of all kinds, beetroot, carrot, onions (sometimes transplanted), parsnip, peas, potatoes, shallots and spinach.

Other vegetables are sown in drills for transplanting at a later date, and these include the following: Cabbages, cauliflower, celery (in boxes), cucumber (in pots), greens, leeks, onions (when specially fine bulbs are required) and vegetable marrows (in pots).

Broadcast sowing is commonly adopted in the case of cabbage and winter greens, cress, endive, lettuce, mustard, radish and turnip.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Where Smoke Prevails.

DECIDUOUS flowering shrubs are generally the most appropriate for town gardens, as these usually succeed under smoky conditions better than the evergreen varieties, owing to the fact that the former cast the whole of their foliage in the autumn and early winter, and the new leaves (the breathing organs of the plants) are produced in the spring, while the latter are handicapped by retaining their leaves through the winter and gradually casting through the spring and summer. The foliage is thus subjected to the most dense period of smoke during the autumn and winter. Under these conditions evergreen plants, while they may exist, seldom thrive where much smoke prevails.

They, however, possess an advantage over coniferous shrubs such as the cedar, cypress, yew, etc. This class of plant is impatient of a smoky atmosphere and is seldom seen in a flourishing condition in town gardens. Much can be done, however, by the use of the hose-pipe or syringe and clear water in maintaining healthy plants in the town garden.

Selection of Shrubs.

The choice of deciduous and sub-evergreen shrubs for the town garden may be made from the following: Syringas (lilac in variety), viburnum (snowball tree), Forsythia suspensa (Japanese golden bell tree), philadelphus (mock orange), Spiræa ariæfolia, weigelas, hypericums (St. John's wort, Rose of Sharon), ribes (flowering currant), Colutea arborescens (bladder senna), the red and white Daphne Mezereum, Olearia Haastii, Osmanthus illicifolius, the barberry (of sorts), skimmias, pyracantha, cotoneasters, laurustinus, etc.

If space is available, several of the deciduous flowering semi-shrubs or trees should be planted; their beauty of foliage and inflorescence presenting a delightful feature in the town garden.

Among these are the prunus and pyrus family, including the almond, acacias, laburnums, white beam, thorns and the maples.

The general cultivation of these shrubs and trees is principally the cutting out of old flowering wood and dead wood and the occasional shortening back of straggling branches to keep the bush in shape and bounds, and, last but not least, syringing the foliage periodically through the growing season with clear water to wash off sooty particles and impurities, and so help to maintain healthy conditions.

Simple Colour Outlines.

Coloured Edgings.

VIVID yellow or mauve violas make bold outlines which are ideal for the small front garden. In this position neatness is often specially desirable, and nothing could be neater than a well kept edging of violas. To ensure success in the cultivation of these plants, it is advisable to dig the soil very deeply during the winter months, incorporating some kind of soil fumigant as the digging is done. This prevents many losses due to the attacks of soil pests. Heavy soil should be lightened by the addition of road grit and strawy manure, and light soil benefits from a dressing of cow manure if this can be obtained.

A selection of violas suitable for those who wish to grow for exhibition purposes would be Mrs. Andrew Stevenson, John Adamson, Milton Jumbo, Chrissie Littlejohn, Mabel Spencer, Malcolm Milner, Wm. Barr, Mrs. H. J. Milner, Mrs. W. R. Milligan, Drummer Wilson, Admiral Jellicoe and John Wood.

The best position for viola culture is in a bed which is open and sunny, but which receives some shade in the hottest part of the day. This, of course, is the ideal, but violas can be grown very successfully in many a garden where the conditions are less suitable. They do not like to be under the drip of trees, but apart from this there are few places where a reasonable measure of success is unattainable.

THE SPRING-FLOWERING DAPHNE MEZEREUM.
A good shrub for the smoky town garden.

Care of the Lawn.

THE lawn now begins to assume a brighter colour with the lengthening days. No feature in the garden gives so much pleasure throughout the year, but a patchy and weedy grass plot detracts from the appearance of the garden no matter how well it may be planted or cared for. The most important thing about the small lawn is that there should be a constant supply of food available to feed the roots. Many amateurs are under the impression that grass, if it is only rolled and mown regularly, will look after itself, but this is far from the truth. In fact, the lawn needs feeding just as we feed our flowers, fruit and vegetables. Each plant, of course, has roots, and forms an abundance of foliage which, to be maintained, must be fed. A neglected lawn should be treated to a thorough overhauling at this season. If there are only a few perennial weeds, such as dandelions, daisies, self-heal, etc., these can be removed by hand, but if the lawn is very weedy it might mean resowing or a drastic dressing of lawn sand, and then subsequent sowing of seeds over the bare patches. Where a lawn has become practically all weeds it is advisable to dig it over and to sow again with fresh grass seed. A useful top-dressing for an impoverished lawn is made by mixing decayed leaves, loam or good garden soil and sand together in equal parts. To this add 1lb. of sulphate of ammonia, 3lb. of superphosphate of lime and 1lb. of potassium sulphate to each barrowload. Thoroughly mix the whole and apply this quantity to 30 sq. yds. of lawn, and sweep the mixture into the grass with a broom, or work in with the reversed side of a rake. The rain will wash it in, and the effect of this dressing will be to stimulate the finer grasses and so improve the texture of the lawn. A suitable quantity of grass seed for sowing a new lawn is 2 oz. to the square yard in the towns and suburbs.

A WELL KEPT LAWN IS ALWAYS AN ATTRACTIVE FEATURE IN THE SMALL GARDEN.
Here is an example of what may be accomplished in small space.

Digitized by Google

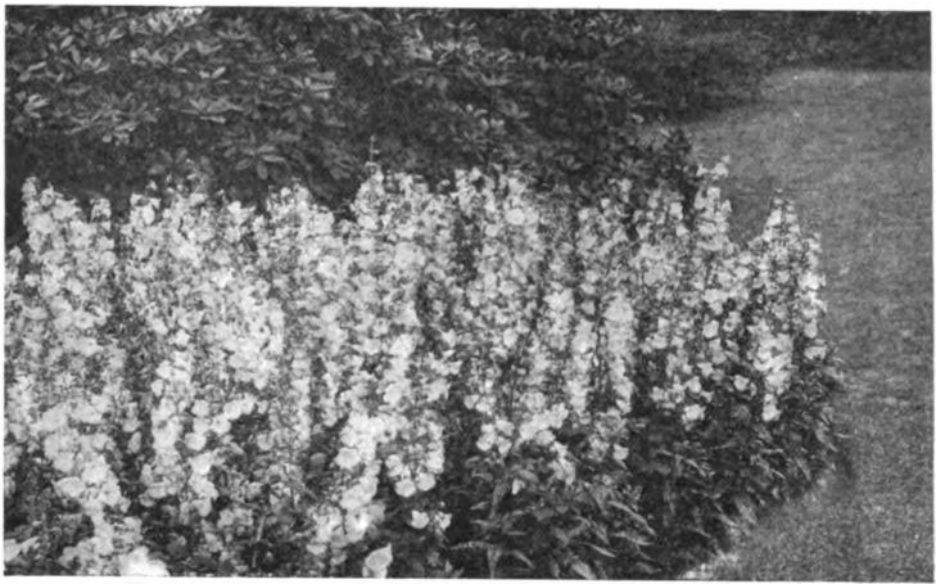
THE PINK AND MAUVE BORDER

PERHAPS the most charming and restful of all colour harmonies is that of pink and mauve. Flowers of these two tones really do blend in the most charming way, as the many delightful groupings in our borders will testify. But why only have odd groups here and there? If there is space to spare in the garden, even for only a small border, it could never be more beautiful than when planted out with perennials and annuals of these two colours. Such a border would necessarily start flowering rather late, for of spring-flowering bulbs very few are of the colour we require. Tulips, of course, have representatives of each shade, and bold clumps of these might be planted. Otherwise, there are few suitable bulbs, unless one includes the tuberous-rooted anemones and ranunculuses.

Early in April, the aubrietias will start blossoming, and carry on till June. There are many dainty varieties, including Lilac Queen, soft mauve; deltoidea, deep mauve; Bridesmaid, soft blush; and Moerheimi, pink. These should be planted towards the front of the border, as they only reach a height of 4ins.

In May will come the pyrethrums, dwarf phlox, violas, saponaria and May-flowering irises. Of the first named, Niobe, blush rose; Celia, bright pink; Agnes Mary Kelway, bright rose; and Hamlet, pink. Among the dwarf phlox are some of our most precious shades of lavender. Subulata pallida, pilosa and procumbens are good in this shade, while there are others with bright pink flowers. Violas embrace many shades of mauve and should be chosen according to taste. Personally, we prefer the beautiful mauve varieties of cornuta and gracilis to the big-flowered bedding sorts. Saponaria ocymoides is a perennial soapwort with masses of lovely pink blossoms, and is another low-growing plant. Bridesmaid, John Bull, Mrs. Reuthe and Sympathy are all meritorious lavender coloured irises.

When June arrives, we are rich indeed in the wealth of blossom available. Nepeta Mussini shall open the list, for it is one of the indispensable plants for our border. It is a toss up whether we edge the border with this or with the dainty single-flowered pinks. Perhaps we shall compromise in the end by alternating the two varieties, and so have fragrance as well as beauty in our border. Besides the single flowered pinks, there are fine double sorts worthy of inclusion, such as Bridal Morn, pink with maroon centre; Clove Pink, with daintily fringed petals; and Floral Beauty, a fascinating shade of silver rose. Other dianthus species are, deltoides (Maiden Pink) and cæsius, the native Cheddar Pink, both suitable for border cultivation. The sweet william is another representative of this family, and the variety Pink Beauty is of a lovely soft shade of pink. Erigerons will also commence to flower now, and their sheaves of daisy blossoms make a great show in the border: philadelphicus, rose; speciosus, deep mauve; and Villarsii, soft lilac, are excellent sorts. The lovely soft lavender blue Quakeress is rather later flowering than most, and will not open its first blossoms until well on in July.



A FINE MASS OF THE SOFT PINK PENTSTEMON DAYDREAM.

Of pentstemons, campanulata and glaber are two good pink species of moderate height, and Scoulerii is exquisite in cool lilac blue. The hybrid forms are less hardy than the true species and more inclined to red, scarlet and crimson shades. Daydream, pink with white throat; Janie Brown, lilac; and Pink Newbury Gem, are the best for our purpose.

Scabiosa caucasica should on no account be missed. The long-stemmed lilac blue flowers are produced freely from the end of June until October and are of exquisite colour and formation. Mr. I. House's new strain contains many charming shades of mauve and lilac and in a number of cases the blossoms are of giant size.

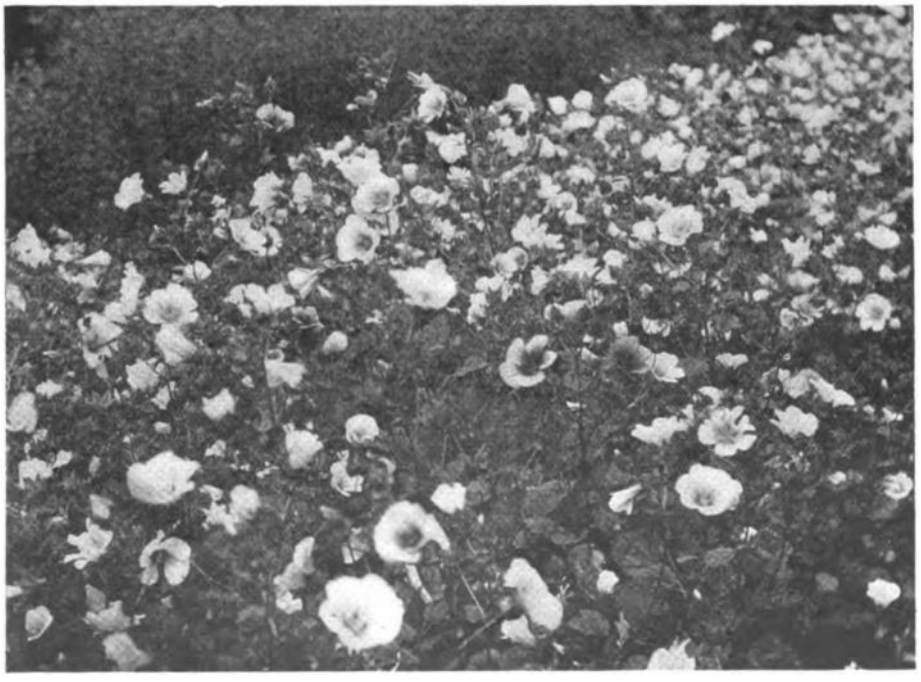
Other flowers of June include armeria (thrift or sea pink), in varying shades of pink; Lupinus polyphyllus rosea, soft pink; and such heucheras as brizoides carnea, rose, 1ft.; sanguinea, Edge Hall variety, rose, 2ft.; rosamundæ, delicate pink, 3ft.; and Rose Queen, 18ins.

With the arrival of July there is even a greater wealth of blossom. Many of the June flowers are still in bloom and many more sorts just coming into blossom. Antirrhinums should be at their best during this month; the favourite, Nelrose, is still one of the foremost pink varieties.

The astilbes (false spireas) and the true spireas will begin to unfurl their feathery plumes about the middle of the month. Both of these should be planted in a moist, shady position, if good results are to be obtained. There are many pleasing pink forms in each section, ranging in height from 24ins. to 7ft. A specialist's catalogue will give much fuller descriptions than can be attempted here, so we will leave the matter at this.

Other flowers that will commence to blossom in July are Malva moschata, glistening pink, 2½ft.; galega (goat's rue), of which officinalis carnea fl. pl. is a double-flowered pink variety; and sidalcea, Rosy Gem being a good form.

From August until November fogs we can have blossom in our border, the very last



THE GLISTENING PINK MALLOWS SHOULD ON NO ACCOUNT BE OMITTED FROM EVEN THE SMALLEST BORDER.

Digitized by Google

to go being the Michaelmas daisies. These will be found in the catalogues under the heading of perennial aster and a whole border could be filled with their mauve and pink varieties alone. However, to restrict ourselves to half a dozen, we should grow Elsie Perry, rose pink, 3½ft.; Perry's Favourite, pink, very large flowers, 2ft.; St. Egwin, soft, pink, 4ft.; cordifolius, Edwin Beckett, myriads of tiny mauve flowers, 4ft.; Thompsoni, pale lavender 2ft.; and Beauty of Colwall, pale lavender, 4ft.

A PLEASANT ASSOCIATION OF MAUVE PHLOXES AND PINK HOLLYHOCKS (PALLING BELLE).

Another border could be filled with varieties of the herbaceous phlox and once again careful discrimination is needful. Three good pinks would be Mrs. Miller, Rijnstroom and Frau Buchner. Some of the best mauves include Lady Dolly, Violetta, Le Mahdi and Crepuscule.

Japanese anemones are very showy perennials, and there are some good rose-coloured forms. They will flourish quite well in a half shady part of the border and are specially valuable for the north border. Mont Rose, semi-double; Rosea superba; Alice crispa and Queen Charlotte, are all pink-flowered kind.

Perhaps the most stately plants in the whole border will be the hollyhocks, either double or single. Palling Belle is one of the most beautiful double forms, with large silvery pink blossoms.

Lavender should be planted, not only for the sake of its blossoms, but also for the beauty of its foliage, which tones so admirably with pink or mauve. Another shrub which might be included for its foliage is Santolina incana, with lovely soft silvery white leaves.

Sedums will close the list, and they are more showy plants than is usually imagined. S. spectabile is undoubtedly the finest form, with broad flat heads of bright pink flowers and pretty glaucous green leaves. Ewersii is another meritorious kind bearing pink flowers, but scarcely so pleasing as the preceding.

Besides the perennials, there are vast numbers of annuals that might be grown. Pink flowered sorts are cosmos, asters, larkspur, lavatera, calandrinia, candytuft, clarkia, godetia and Shirley poppy; to mention but a few. Mauve flowered annuals are not quite so common, but we could plant collinsia, echium, ageratum, aster, stocks, candytuft, clarkia (Mauve Queen), Salvia Horminum and double godetia.

These annuals may be sown outdoors during April, and perennial species during the month of March. The border must be dug at least two spits deep, and enriched with rotted manure, leaf mould, etc., as the digging proceeds. It is not advisable to plant the perennials immediately after the border is dug, so this work should be got in hand as soon as possible now. It is also advisable to order now all seeds and plants required from our advertisers. B. D. S.

NEPETA IS AN INDISPENSABLE PLANT FOR A PINK AND MAUVE BORDER. IT MAKES AN EXCELLENT EDGING.

ERIGERONS WITH THEIR SHEAVES OF DAINTY DAISY-LIKE BLOSSOMS MAKE A BOLD DISPLAY IN THE EARLY SUMMER BORDER.

HOW TO PRUNE YOUR ROSES

Now is the time to prune the rose bushes in the garden if these are to flower well during the summer and autumn months. The instructions given in this article by an acknowledged authority should be followed closely. They are based on the methods followed at the Royal Botanic Gardens, Kew, where every year the rose beds form one of the most attractive parts of the Gardens.

WHAT to the experienced rosarian is a comparatively simple operation, is regarded by the beginner as a very difficult and mysterious affair. I shall, however, try to explain as simply as possible the methods of pruning various classes of roses.

Dwarf-growing Roses.—Hybrid Teas and Teas.

If, for example, we start at the beginning, and take a rose that was planted last autumn, it, in common with nearly all newly planted roses, should invariably be pruned hard back to within three or four buds of the base. In some cases there is very little choice, for if the wood is soft and unripened, as sometimes happens, it may be necessary to prune back to one or two buds, always remembering that one must prune back to hard, firm wood. This applies to tea roses and also the old hybrid perpetuals, as well as to ramblers, unless they have been pot-grown, then a portion of the shoots may be retained nearly full length.

Here, however, we must note an exception to the rule, and that is when dealing with the climbing varieties of well known dwarf hybrid teas and tea roses, of which Mme. Abel Chatenay, Lady Hillingdon and La France are well known examples. They must not be pruned hard back the first season after planting, as, for some reason, this has a tendency to stop their climbing habit. Where it is necessary to plant roses during the spring, they should be pruned hard back at the time of planting.

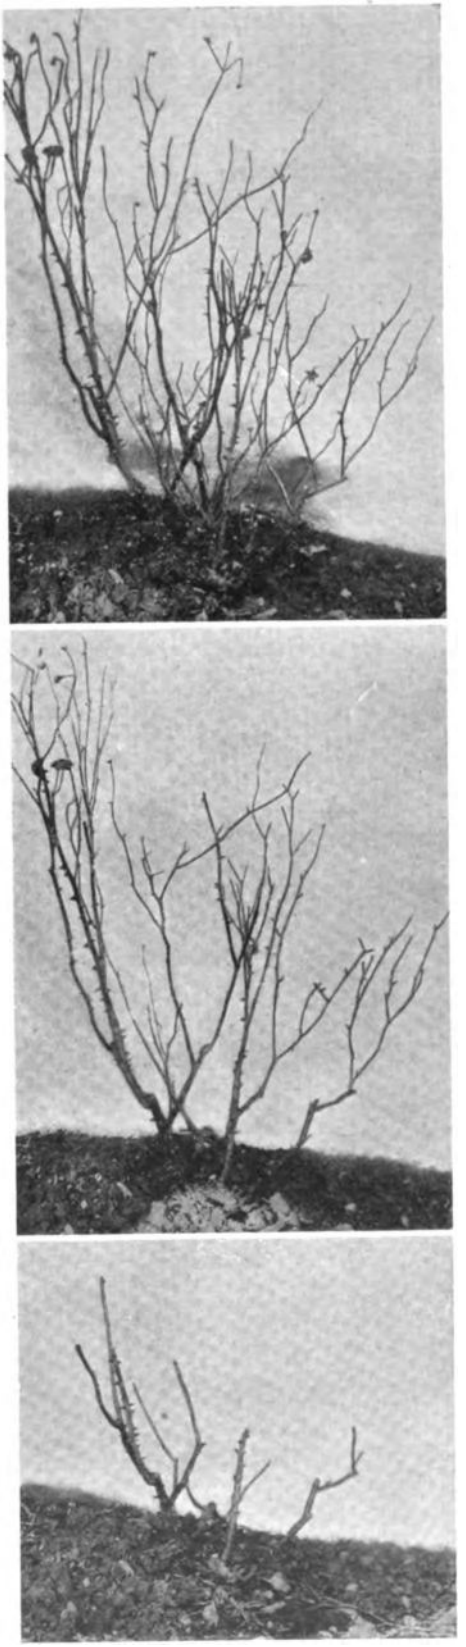
We will now consider the pruning of the same class of roses, *i.e.*, the dwarf types, in their second and subsequent years. Fig. A shows an unpruned bush. The first part of the operation is the removal of all dead, weak and unripe wood, which should be cut right down to the base. Fig. B shows the same plant after the preliminary thinning out; while Fig. C shows the completed operation. In this case it is assumed that the plant is being grown for decorative or garden purposes. When pruning for the production of exhibition blooms, the same plant would have more shoots removed and be pruned harder back.

When pruning, branches that cross one another should, if possible, be removed. The shape of the bush must also be considered, keeping it open in the centre; to ensure this, always prune back to an eye pointing outwards; or, if the centre or any portion of the plant is too open and unfurnished, prune back to an eye pointing in the direction it is desired to close up. In the case of some varieties of sprawling growth it may be necessary to prune to an eye looking inwards or upwards. Another important point in pruning is the position of the cut; it must not be too far beyond the eye, thus leaving a snag which dies back and, in so doing, may involve the eye. On the other hand, it must not start too low down, but just slightly above the eye, starting the cut from behind the eye and sloping it slightly upwards.

While no hard and fast rule can be laid down for pruning, a good general rule is to prune weak-growing varieties hard and the strong-growing ones lightly; while some of the very strong-growing varieties are only seen at their best when pegged down, which operation I shall describe later on.

Hybrid Perpetuals.

The illustrations on the opposite page show an unpruned plant, the same plant after the first thinning, and, in the inset, pruned hard back for exhibition purposes. If grown for decorative work, the shoots would be left somewhat longer.



A.—A HYBRID TEA UNPRUNED.
B.—OLD WOOD AND WEAK SHOOTS REMOVED.
C.—PRUNING COMPLETED.

Standard and half-standard roses are greatly favoured by amateurs, and in their cases the same general principles apply. An unpruned half-standard and the same plant with the pruning for decorative work completed are also illustrated. If grown for exhibition work the pruning would, of course, be more severe.

Pegging Down Roses.

There are a number of strong-growing roses which can only be seen at their best when the long shoots are left almost full length and pegged down to within a foot or 18ins. of the ground. They may make annual growth of from 6ft. to 8ft. in length. This may be pegged down full length with the exception of shortening the end of the shoot, which may be soft and sappy. Also, the buds on the top portion, at the time of pruning, generally have started into growth; then it is necessary to prune back to a dormant eye: this is essential in pruning all types of roses.

The pegging down of the long shoots causes every bud to start and produce short lateral shoots, each one of which is terminated with flower. Next year the pegged down shoots should be cut out, and the young shoots made the previous year pegged down in their place. If it is necessary to retain any of the old shoots for filling in the space, the lateral growths made the previous season should be pruned back to within two eyes of the base. Varieties that are well suited for pegging down are Hugh Dickson, Lady Waterlow, Gustave Regis, Frau Karl Druschki, J. B. Clark, Mme. Isaac Pereire and Grüss an Teplitz, or, in fact, any rose that makes shoots sufficiently long to peg down.

Tea Roses.

The dwarf varieties should be pruned in much the same way as the weaker-growing hybrid teas. Often there is very little choice in the matter, after the dead, weak and soft unripened shoots are cut away there is often very little left, and that may have to be cut down to the ground line. The stronger-growing varieties should be pruned on much the same lines as the weaker-growing hybrid teas.

China Roses

usually require the same treatment as the teas, although some of the stronger-growing and hardier varieties make large bushes: they, of course, must be more lightly pruned.

Dwarf Polyanthas.

It is often advised in the books to prune this class very lightly. My experience of them, over a long term of years, is that they give the best results for bedding purposes when they are pruned fairly hard. As it is important to keep plenty of young wood in them—and with all roses that means cutting at least one shoot, or shoots, hard back each year.

Rambling Roses,

as represented by the multiflora and Wichuraiana varieties, should, as a rule, be cut hard back the spring after planting, although, if planted early the previous autumn, some of the shoots may be left fairly long. When all the shoots are cut back, no flowers are produced the first season, as this class generally flower on wood made the previous season. Once established, the pruning of this class of rose should be done as soon as possible after they have finished flowering, in most cases cutting the old flowering shoots right out, thus making room for the young

From left to right: A HYBRID PERPETUAL UNPRUNED; AFTER FIRST THINNING; (*inset*) PRUNED FOR EXHIBITION BLOOMS; A HALF STANDARD UNPRUNED; PRUNING COMPLETED.

growing shoots, which, in their turn, will flower the following season: remembering always that it sometimes may be necessary to retain a few old shoots, as the first object is to get the desired space, whether it be a trellis, archway or pergola, fully furnished as soon as possible.

Time to Prune.

One is often asked what time one can safely commence pruning. This, of course will vary in different parts of the country, but generally one can start with the hybrid perpetuals about the beginning of March, following on with the hybrid teas and pernetiana varieties; while teas and noisettes should be pruned during April. The danger of pruning too early is the fact that the buds start and growth may be too advanced before all danger of spring frosts is past.

Pruning Tools.

Very few are really necessary, but they should be of the best quality, and should consist of a moderate-sized pruning knife and a hone for sharpening the same; also a small pruning saw with a straight, narrow blade; a pair of good secateurs; and easy-fitting pruning gloves. In pruning dwarf roses a kneeling pad adds greatly to the comfort and convenience of the operation, although some affect to despise this as a luxury. It is very important that the cutting tools should be kept in perfect condition. J. COUTTS.

WHAT OUR READERS SAY

THE SENSITIVE PLANT.

SIR,—A very interesting and easy plant to grow is Mimosa pudica, although the true sensitive plant is Mimosa sensitiva, M. pudica is more sensitive to touch.

It may be propagated by seeds sown during the spring in a hot-bed, or by cuttings, which should be of the firm young shoots inserted in a sandy soil in heat. From the seedling or cutting stage, plants should be on in a compost consisting of equal parts potted of loam and peat, with a small portion of sand added.

This is usually treated as an annual, and has a herbaceous stem with stalks with stiff hairs at the apex. But under stove conditions it assumes a perennial character.—C. J.

CARROT FLY.

SIR,—I have read with interest your issue for February 12th, and I find, in the page relating to the kitchen garden, a note on the carrot fly. May I give your readers a good remedy to do away with the grub that spoils the carrot bed, and which I find successful?

In my own case, the carrot bed, which I get ready in autumn, is prepared in the following way. I dig out a trench, the same as for celery, to a fair depth for long carrots, then riddle all the soil, which will leave stones, etc., in the riddle, which can be used for a footpath.

Make up the trench with the fine soil to within 3ins. from the top. Now procure about half a sack of sawdust and steep it in about two gallons of paraffin — more if the sawdust will soak it up. Now spread this on top of the soil in the trench about 1in. thick, and rake it in the soil in the trench.

Put in the remainder of the soil to fill up the trench and let all settle awhile—which is important, as carrots do not like too loose a soil.

I find this method a good one for turning out a decent crop of clean carrots. I have tried the sand method, but find that the smell of paraffin does not keep a long while.

As there is yet time for soil preparation, I thought it would be suitable for other readers who are troubled with carrot fly.

I like your paper, and hope you will have much success.—BENJAMIN HALSTEAD, *Dewsbury, Yorkshire.*

MAKING A NEW GARDEN.

SIR,—A brief account of how we dealt with our own awkwardly sloped land may possibly suggest ideas to "North Herts."

In the first place, we employed a "garden architect" to make a plan, but his suggested "lay-out" was altogether too elaborate. We were very definite on two points: First, the ultimate garden must be such that we could run it with one man and ourselves; secondly, the "lay-out" must be such that it could be carried out by our knowledgable handy-man and ourselves. We, therefore, set to work on a scheme of our own planning.

From the north, east and south boundaries the land rose steadily, but unevenly, to an eminence situated roughly about the middle of the plot. On this eminence the house was built. From the road a short winding drive ascends to the front door on the north front. At the gate the sloping banks of the drive (planted with Cotoneaster microphylla) are close on 5ft. deep, but they graduate till they are lost in the artificially made plateau which forms the forecourt. Somewhat steep banks of shrubs flank this plateau—on the north towards the tennis court and wild garden, on the east to a lower level where lie the herbaceous, and further shrub borders.

Though the entrance door faces the road, the south or garden elevation is, in fact, the front of the house. From this point the gradient originally was fairly steep. The ground now falls away in a flight of three terraces. Terrace No. 1, 10ft. wide, we use a good deal as a sitting-out place. Wide semicircular steps lead down to terrace No. 2 (1ft. 8ins. lower); this terrace is laid out as a formal rose garden, with paved paths and turf surround. It is 23ft. wide and 64ft. long. At either end a clipped Cupressus macrocarpa hedge breaks the wind from east and west. The wide central path across the terrace is bifurcated by a semicircular bed, and two flights of steps lead on to the last terrace—the drop is only 15ins. Terrace No. 3 is a lawn 23ft. at the widest part. The edges of the two upper terraces are straight, in this case the edge is serpentine and is skirted by a winding path which lies 2½ft. below, reached by a final flight of steps.

Terrace No. 1 is carried round the east end of the house and leads on to the forecourt. Terrace No. 2 (of grass) is reached by steps, and stepping-stones set in the grass form an introduction to the rock garden, whence they lead. The rock garden is in two bold irregular terraces. We increased the natural

Digitized by Google

decline of the land here by excavating a path at the bottom.

Throughout the garden the terraces are supported by "dry walls." The rock garden paved paths, steps, walls and edgings are of Bargate (Godalming) stone in varying sizes and thicknesses. The same material, broken, has been used instead of gravel on the upper terrace and on all the paths and the drive. Bargate sand was washed in among the broken stone and well rolled, and the resultant surface is almost like concrete. With the exception of the tennis court and the drive, my husband and I and our handy-man carried out the scheme, the latter doing the lion's share.

The preliminary outlay was, of course, somewhat costly, but I particularly wish to emphasise the subsequent saving of labour. The hard close surface of the drive and paths does not encourage the free growth of weeds, and only requires weeding once every eight months. After the first year the "dry walls" have required no weeding to speak of, and, furnished with suitable plants, are beautiful at every season. The effect of a terraced garden, such as I have described, is to add in a most deceptive manner to its apparent size.

To level the tennis court, it was necessary to remove 6ft. from one end and build it up to a similar amount at the other. I would suggest that "North Herts" should begin by "skinning" the rough turf off the entire surface of his plot, removing, where possible, the roots of nettle, dock, etc. The turves should then be stacked, wrong side up, to rot. A year hence "North Herts" will congratulate himself on a most valuable asset in a goodly stock of fibrous loam.

Without seeing the ground and the shape of the depression it is difficult to advise, but would not this depression lend itself to the formation of a natural and very charming rock garden?—GWENDOLYN ANLEY, *Woking*.

WOODLICE IN THE GARDEN.

SIR,—There has been some correspondence recently about Woodlice in the Greenhouse, one reader advocating their extermination by chickens and various baits. To empty a house, or houses, is a costly business, especially during so busy a season.

I can thoroughly recommend, from experience, a preparation called "Woodlice Bait," made up by Messrs. George Monro, Limited, Covent Garden. It is simply dusted on the stages, heavily towards the back and front, and the pots re-staged back over it. I found, one heavy dusting sufficient to rid my houses, which were literally swarming with the pests. Care must be taken not to dust over the foliage of plants.

It may be of interest to add that this mixture succeeded where various soil fumigants and insecticides had failed, and it was equally effective with millipedes.—B. G. M., *Dublin*.

WHITE FLY IN THE GREENHOUSE.

SIR,—I am much troubled with white fly in my greenhouse—some 36ft. by 12ft. The house is full of every sort of plant, both tender and hardy, and is heated. It first appeared on tomatoes last summer and has persisted ever since, and I am dreading its increase in the spring. I find tender plants will not stand fumigation by the advertised remedies; I have tried this in a small way. Can any reader assist me?—SIGMA, *Cobham*.

NEW POTATOES WORTH GROWING

In this article, the report of an interview with Mr. Donald Mackelvie, the well known raiser of potatoes, our correspondent describes a few new varieties and also gives hints on how successful results may be obtained.

WHEN I found Mr. Mackelvie he was hard at work in his potato shed, sorting out his latest seedlings. Behind him were stacked, tier upon tier, boxes containing some thousands of unnamed seedling tubers. Each year, it is said, he grows about 3,000 varieties in his trial ground at Lamlash. Although a man chiefly concerned with the science of hybridising and introducing new varieties for growing on a large scale, I found him to be keenly interested in the small-holder and gardener.

The first question I put to him was with regard to the most suitable variety of his "Arran" potatoes now in commerce for garden cultivation. His answer was "Arran Consul," and he proceeded to point out its advantages as a potato for small growers. The first thing was, he said, that it had regular sized tubers—a boon to the housewife—and then that it produced very little—in fact, the minimum—of seed and chats. It could be grown closely, and so was better suited than some of his other varieties to the system of "inter-cropping" adopted by some amateurs. The haulms were never unduly large, and thus would not overshadow neighbouring crops. The tubers did not spread themselves out at the root, and when digging the "crop" was always to be found in close proximity to the main stem of the haulm. The most important point of all that he mentioned was that Arran Consul strongly resisted ordinary blight, which is such a scourge to the small grower, especially when he attempts close planting. Arran Consul is, of course, immune to wart disease, as we see upon reference to catalogues. When Mr. Mackelvie first started potato growing, his aim was threefold, namely, to produce in potatoes, crop, quality, and resistance to blight. He has certainly achieved his aim in Arran Consul, with the addition of the immunity to wart disease. I also asked him about Arran Comrade, which is also a well known "immune" variety, but he thought that Arran Consul would be preferable for the small grower.

Arran Victory, he said, was another variety which he could recommend, but it had a coloured skin. In Northern Ireland, however, 50,000 acres, a third of the total acreage, had been planted with Arran Victory, which speaks little for the supposed prejudice against dark-skinned potatoes in some marketing circles. At any rate, the cook will forgive the "red skin" when she finds that the flesh of the potato is white, and that it has an excellent flavour when cooked. Mr. Mackelvie believes that the time is coming when all prejudice against dark-coloured potatoes will be removed.

I pointed out to him that the cropping of both these varieties was, perhaps, on the late side, particularly the latter one, and suggested that he should recommend a first early one as well, that would only occupy the ground for a short time. He said that he had some fine early seedlings coming on, but they were not in commerce yet. He had been specialising in heavy-cropping maincrop varieties. Arran Consul, of course, should be classed as an "early" maincrop; it crops just after Majestic and before Arran Chief.

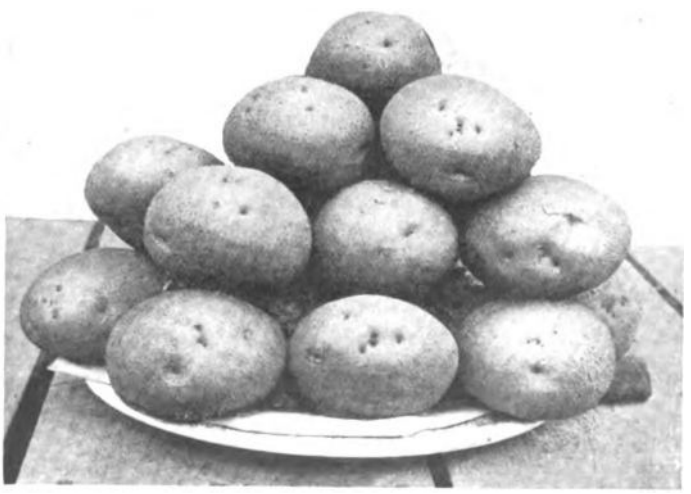
Asking him the distance he plants his strong-growing maincrop varieties, he said that the practice with him has been 9ins. to 10ins. between the sets and 27ins. between the rows. But that is in the fields, and in a garden he might plant a blight-resisting potato such as Arran Consul rather closer.

As to manuring, he thinks that good farmyard manure is always the best. Bone-meal, also, when planting, is beneficial. The chief ingredients in artificial manure should be ammonia and potash, and he gave me his formula: When using farmyard manure — ¼cwt. sulphate of ammonia, ¼cwt. super-phosphates and ¼cwt. sulphate of potash per acre; when not using farmyard manure — ¾cwt. sulphate of ammonia, 1cwt. superphosphates and ¾cwt. sulphate of potash per ¼ acre.

The above is what he uses in his Arran potato fields, and it is easy to reduce it down to the proportions of a smaller plot. The soil that best suits the potato, he said, is a medium loam, and it should be well worked before planting. The planting season with him is from March 15th to April 15th.

His advice about the general cultivation is short and to the point, namely, "keep on hoeing." Of course, there are times when the soil is too sticky to be touched, but, to quote Mr. Mackelvie at a recent lecture, "If only potato growers in general 'cultivated' their potatoes by using the hoe freely, the crops would be substantially bigger and cleaner."

E. W. TATTERSALL.



ARRAN CONSUL, A GOOD EARLY MAINCROP VARIETY FOR THE AMATEUR GROWER.

Especially suited for growing in small areas.

PROPAGATION OF BEDDING PLANTS

IT frequently happens that one is not able to take and root the required number of cuttings during the autumn months, owing to lack of growth of old plants during the summer months. There are instances, too, where there is a great reluctance on the part of the gardener to mutilate the plants when, perhaps, they are at their best as regards flowering. If there is a deficiency of plants now, spring propagation should be undertaken to increase the stock. If care be taken in the selection,

trimming and rooting of the young slips, the spring-struck stock will be a very useful one. In the autumn nearly all cuttings inserted are cool rooted, that is, they are not subjected to any bottom heat. But in the spring roots must be formed quickly and a little bottom heat will be helpful. There is, in addition, more sun heat, so that the work of propagation is facilitated. Owing to the dark days of winter, and the necessity for crowding the stock close together, many plants are drawn up and become lanky. Such are not very suitable for bedding out without being first topped. The tops should not be thrown away as useless, for they are very useful and can be soon turned into a young stock of well rooted plants.

Even such plants as lobelias can be treated in this way. Shoots similar to those shown at *a*, *a*, *a*, may be cut off and inserted in a mixture of sand and leaf-soil, when they will, with the aid of slight bottom heat, become rooted, as shown at *b*, *b*. The old plants of fuchsias, when judiciously pruned back, soon emit young shoots suitable for cuttings, similar to the one shown at *c*. In this case six cuttings can be inserted round the sides of a 3½in. pot. The earliest rooted should be potted off separately, the later ones retained in their cutting pots, hardened and planted out direct from the pots. Zonal pelargoniums that become drawn are represented by the one in the accompanying sketch. First, pinch off all flower stems shown at *d*, then sever the stem at the point *e*, remove the lowest leaf and the cutting is ready for insertion in a sandy compost. Soon after the top has been cut off, young side shoots will grow from the axils of the lower leaves, *f*, *f*, *f*, and they will soon form a good bushy specimen.

It is absolutely essential to success that the main stem be cut off just below a joint. If severed mid-way between these long joints in drawn-up stems, the base of the latter, *g*, will rot and not emit roots. The lowest leaf, *h*, should also be cut off as shown. Now, these principles should be applied, as far as possible, when taking, making and inserting all kinds of cuttings. Then there are tubers to be dealt with. Although tuberous begonias can be raised wholesale from seeds sown in heat now, there may be some varieties of which more are required to fill certain beds. In a case such as this, division of old tubers will give good results. The tubers are first started gently in heat and when the young shoots are approximately 2ins. high, sever the tuber, as shown, from *i* to *j*. Rub powdered charcoal on the cut part of each section, as shown at *k*, and then pot or box each section as a distinct plant. It is only necessary to be extra careful not to apply too much water, then roots will grow normally. All tiny young shoots of such plants as coleus, iresine, alternanthera, sweet-scented verbena and lobelias should be inserted rather closely together in a light, sandy compost in boxes in heat and be kept consistently moist at the base. G. GARNER.

FRUIT AND KITCHEN GARDEN

Preparing Materials for Protecting Fruit Trees.

LATE frosts often do a lot of damage to fruit blossom, late in spring where it is not in some way protected. The frosts come suddenly, as a rule; there is not much warning—sometimes none. At night the weather may seem to be quite settled; the following morning the ground is white with frost; but the sun suddenly shines very brightly, and the unprotected flowers are soon blackened, the pistil of every exposed flower shrivels, and the fruits are lost—a blank for another year. Begin in good time to make the preparations. Hunt up old sacks, rip them up, doubling their size; roughly sew several together, and you have, at once, a sound protecting sheet for a large plum, apricot, peach or nectarine tree on a wall. Many fine, sturdy apple and pear trees are now grown bush-shaped in our gardens. If five tall stakes are driven into the ground, one in the centre and the others to form a square, it will only be necessary hastily to throw over them the sheet of old sacks or the piece of tiffany, or an old herring net doubled, and to fasten it down at each corner, to ensure, perhaps, a fine lot of blossom on a specimen tree. Espaliers may be protected in a similar way; also gooseberries. Bush fruits, grown under wire cages, are readily protected by larger sheets of tiffany or sacking fixed to long slender poles, to be rolled up when not in use and unrolled instantly when needed. Strawberry borders must be protected to ensure a good set of berries. String nets are used to exclude birds, and they may also be fixed on wires or strong laths to protect the blossom; but it is advisable to fix small-meshed wire netting round the bed, to save the string nets, which are then kept entirely free of the soil. The wire netting and the horizontal supports for the nets can be placed in position now. There is always a lot of urgent work to be done at the time when fruit trees are in flower.—X.

Fig Trees on Walls.

THE fig tree grows very strongly in a suitable rooting medium. Trees are sometimes planted in positions where there is not sufficient space on the walls for the due training of the branches without overcrowding them and thus losing the crops of fruits, or the severe character of the annual cutting necessary to keep them within bounds also causes loss of the crop. Frequently one finds such trees growing bush-form away from and above the wall. Judicious manipulation of the shoots, in a case of this kind, will result in really good crops of figs. All fig trees should be finally examined now for the removal of superfluous branches. These are the weakly ones, which are quite useless and should be cut out close up to the bark of the larger stem. The stronger branches retained should be trained to the wall, provided there is room without undue crowding, their full length. In due time very strong shoots will grow and they can be reduced in numbers by pinching the very sappy ones out while they are small. Where the fig tree forms a bush very similar treatment will be suitable. The object should be the growth of branches which will ripen and a good crop of figs. The stopping of young shoots bearing embryo fruits will be a work to be attended to later.—A.

The Uses of Spreaders in Spraying.

SPRAYING of our fruit trees must soon be carried out, and it is advisable to pay attention to the use of these materials to render the various sprays more effective in their use. If one sprays a plant with water and after spraying, examines it with a magnifying glass or even with the naked eye, one will see that the water is distributed unevenly over the surface of the plant in little globules or drops. The same thing occurs when spraying with most insecticides and fungicides. Thus parts of the plants sprayed are left untouched and the efficacy of the spray is greatly impaired.

To obviate this, and to secure an even distribution of the spray fluid over the plant in the form of a film, certain chemical compounds are added to the spray. These compounds are known as spreaders. In reality they lower the surface tension of the spray fluid so that it assumes a flattish shape rather than a globular one.

The most efficient spreader in general use is soft soap, others are flour paste and calcium caseinate. Unfortunately, soft soap cannot always be used, because of the hardness of some of the waters in certain places. Hard water contains mineral salts, mainly bicarbonates and sulphates of magnesia and lime, to which its hardness is due and on adding soft soap to these waters the fatty constituent of the soap combines with these mineral salts, forming an insoluble curd. It would be necessary to add sufficient soft soap to remove these mineral salts and then more to act as a spreading agency. In many cases this is far too expensive a procedure.

An alternative method is to use rain-water, but this is only possible on a small scale. Soft soap cannot be used as a spreader with lime sulphur as a chemical action occurs which decomposes the lime sulphur.

Digitized by Google

Fortunately, in calcium caseinate we have a substance upon which the hardness of the water has no effect and although it is not as efficient as soft soap, it can be used to advantage with lime sulphur and other sprays or with very hard water. For spreading purposes, use about one quarter of one per cent., or 2½lb. per 100 gallons of lime sulphur spray and mix well with the spray.

Flour paste is also recommended, but it is not so good, as it is sticky and is liable to block up the stomata of the plant. Skim milk may be substituted for calcium caseinate where only a small quantity of spray material is required.—H. D. BENNETT.

Runner Beans in Boxes.

YOUNG runner bean plants are very tender and are soon killed by frost. If the seeds are sown in a cold, wet soil, they will rot instead of germinating. Plants raised under glass and, in due course, planted out and afforded ample protection for a time, will begin to flower at an early date, and the long tender pods resulting will be ready to gather several weeks before those borne on plants raised in the open border. If the boxes used are about 6ins. deep, they may be of any size as regards width and length. In the bottom of each box, which must be adequately drained, place some well rotted manure, quite 1in. deep, then rather lumpy fibrous loam in which all grass roots are dead, almost to the top of the box. Sow the seeds by dibbling them in 4ins. apart and 2ins. deep. The compost should be on the dry side and made moderately firm, before the seeds are sown. Do not apply water too soon; the moist compost will cause the seeds to begin to swell the first week, then a good watering will result in extra swelling and the first growth. Afterwards allow the soil to get moderately dry each time before applying more clear water. Any shelf or stage in a greenhouse will do for the boxes and their contents, if not shaded, until the first rough leaf appears; then more air must be admitted and frame accommodation found for the plants until the first week in June, when it will be safe to transplant them 1ft. apart in the prepared trenches. I always draw up a high ridge of soil to both sides and place small branching sticks to the plants directly they are planted out, as I find that such treatment is sufficient to protect the plants from cold winds and to support the young runners which are, at this date, growing freely. The final sticking should be done about a fortnight after the planting. Runner beans root very deeply into the soil, and it is advisable to open deep trenches, quite 30ins. deep, and to mix rotted manure liberally with the soil as it is returned to the trench up to within 6ins. of the top.—HANTS.

The Globe Artichoke.

THIS vegetable is not so often seen in amateur's gardens as its merits deserve. The edible part of the plant, which is the head, is produced from July to October. To ensure heads of the finest quality a deep rich loam is the best, but heads of a good size can be produced on any garden soil that has been well dug and had a liberal dressing of manure well incorporated with it. As the fleshy roots penetrate to a good depth, deep working is necessary. If the soil is heavy and retentive, road scrapings and coal ashes may, with advantage, be added to it.

Propagation is effected by off-sets or suckers, taken from around the base of the old stools in April. These should be about 10ins. in length, with some fibrous roots attached. Remove the rough outer leaves and plant out the young plants about 3ft. apart, with 4ft. between the rows, making the soil firm around them.

After planting, place 3ins. or 4ins. of very sandy soil or coal ashes around them, mulching the intervening space with long strawy manure. If the weather is dry, give water to ensure the young plants starting into growth quickly. The periodical use of the hoe is necessary to keep the soil free from weeds, and through the summer there must be heavy waterings in hot, dry weather.

Failing a stock of stools, seed may be sown in drills 18ins. apart in March or April. Thin the plants to the same distance, which will be sufficient space for the first year. Seed may also be sown in gentle warmth in March, the young plants placed singly into small pots and transferred to larger ones when necessary. Gradually harden off before planting out in May. A bed will remain profitable for about three years, after which the heads become too small to be useful.

Plants that are to remain another season should have all decayed leaves and old flower stems removed, and the ground lightly forked over and 5ins. or 6ins. of coal ashes placed around the stools.

If severe weather sets in, additional protection should be given by surrounding with bracken, leaves or strawy litter; it is also well to cover the tops of the plants lightly with bracken in the event of snow, which is frequently the cause of the loss of plants when it gets into their crowns. Remove the bracken in March, fork in a dressing of well decayed manure, as well as the ashes. Green Globe and Purple Globe are good sorts, but the best variety, especially for exhibition, is the Large Green Globe.—F. M. H.

Early Autumn Broccoli.

EVEN without a garden frame a few early plants can be raised that will fill a gap, perhaps, between the late autumn cauliflowers and the earliest broccoli. A large wooden box should be treated as if it were a garden frame by placing a few sheets of glass on it. Either frame or box, whichever is used, should be placed on a mild hotbed, if the materials for it are available. No attempt should be made to force the growth, but simply exclude frosts. Sow the seeds in boxes quite 5ins. deep and fill them with new loam, if such can be procured, in preference to old garden soil. With the new loam mix a small quantity of builder's old mortar rubble. When the seedlings are showing the second rough leaf, carefully transplant them into other boxes filled with a similar compost. Press the soil gently to the roots, but do not press the tiny dibber against the stems of the seedlings. Harden off the young plants gradually and then transplant them 6ins. apart in a nursery bed outside prior to planting them in their permanent quarters in June. If the whole of the soil cannot be manured, take out soil 1ft. deep and of the same width, forming a trench, put in well rotted manure, replace the soil and plant the broccoli 2ft. apart, treading down the soil firmly directly it has dried a little. In this way strong plants can be grown. Michaelmas White, Grange's Autumn White and Veitch's Self-protecting are very fine varieties.—G.

Some Hints on the Arrangement of the Crops.

BEFORE any seed sowing or planting is done on a large scale, the cultivator should carefully plan the various main crops, decide where they are to be grown. The winter greens must occupy a considerable space, eventually, in the garden, but it would not be economical to leave that particular plot of ground vacant until the winter greens are available for planting. Every square yard of ground should, if possible, be cropped all the year round and, furthermore, take two and three crops off some of the plots. If you plant early potatoes, early peas, lettuce, radishes, and so on, the crops will mature for clearing off the ground in good time for the planting of the winter greens. Therefore you should select the warm positions for these early crops. Such quarters will be the best ones for the winter greens; planted there the crops will grow sturdily through the late summer months and, being of firm growth the plants will withstand any severe frosts that may come. Contrast such sturdy plants with those grown in a very cold quarter of the garden, perhaps in partial shade, too. The growth will be more luxuriant, but it will not withstand frost as well as the firmer growth. Again, it is well to grow late summer or early autumn maturing crops in those naturally cool or partially shaded plots—if such exist in a garden. The row of runner beans should always be where the sunshine can reach both sides, if possible. Where this arrangement is practicable and the roots of the plants can penetrate into a naturally moist soil to a great depth, then those long, straight pods, so much coveted, will be obtained in abundance. The roots of the runner bean plant will penetrate a rich, well tilled soil to a depth of 30ins., and if such a soil can be used, it should be, even if the runner beans shade, heavily, some other crops. The isolated north to south rows of peas in the potato plot are, nearly always, the most heavily laden of all rows, with well filled pods. The long-rooted beets and carrots should occupy a naturally deep soil; the stump-rooted carrots and the round beets the most shallow soils, for preference. In this way all the garden space will be economically cropped. The celery rows should be formed where there is ample space for soil earthing up. Odd borders can always be occupied profitably with odd crops.—G. GARNER.

How to Grow Fine Parsnips in Heavy Soils.

I HAVE not used the word *big* as it is a comparatively easy matter to grow such and have them rough and coarse. I use the word *fine*, as such are most desirable and the most difficult to grow in a heavy, clayey soil. Big parsnips with cankered, rotted crowns I think are the most objectionable of all vegetables. In the first place, the staple soil must be deeply dug or trenched and well broken up. In the meantime some finely sifted soil should be obtained and stored in a dry place. If the ground has been trenched last autumn, so much the better for the work of sowing and, also, for the resultant crop of roots. When the weather is dry enough rake the surface of the soil lightly early in the morning. By midday it will be dry enough to tread upon without adhering to the boots. Make holes with an iron rod or a pointed stake 30ins. deep and about the size and shape of a good specimen root. Partly fill the holes, which should be 1ft. apart, in rows 18ins. asunder, with the sifted soil in which some bone meal has been mixed. Gently prod the dry soil with the round handle of the rake to firm it in the hole; then fill up with more sifted soil and firm it. Wood ashes may be mixed with the whole of the sifted soil, but bone meal with the lower portion the lower two-thirds—then the roots will go down after it and the seeds will not come into direct contact with it nor the crown portion of the root. Cover the few seeds sown in each hole about 1in. deep, also with the dry sifted soil and press it down firmly with the fingers. Do not water; the dry soil will gradually become moist, the seeds will germinate and not decay, and the resultant roots will be fine ones, not coarse, if the ground is well hoed during the summer and kept free from weeds. In such soil it is better to sow now for exhibition roots than early in January and have stunted plants as a result.—CHRISTCHURCH.

GARDENING UNDER GLASS

Red Spider.

THESE tiny mites are difficult to see, but exceedingly destructive when allowed to become numerous. They may infest any plant and the most obvious signs of their presence are flabby leaves, leaves spotted, blotched and limp, and a woebegone appearance of the host attacked. Hot, dry, forcing conditions cause them to increase at an astounding rate, so that they may become a menace just now under glass, in frames, on trees against warm walls and in similar places. The first step in eradication, the best preventive where they are feared, is to maintain moister conditions, in fact, to keep plants and atmosphere as damp as can consistently be done without doing harm. In addition to that, an efficient wash is required, an insecticide it may be called. The new Red Spider Deaths now finding their place on the market are proving first-class when used as directed either to eradicate or to prevent the spread of the trouble, and can certainly be recommended. An older cure, but a very good one, is 1oz. fine sulphur stirred into soapy, tepid water (1oz. to 2oz. of soap per gallon); indeed, dry sulphur is quite good in itself, if carefully dusted where the pests abound. Nicotine and many proprietary insecticides are moderately good, but in all cases the thoroughness of application, so as to treat all parts of the leaves, the branches and surrounding woodwork or stonework, is the main reason of success. Fumigation in the ordinary way is very doubtful. As in all attacks of pests, washes should be applied at short intervals until immunity is secured.—CLYDESDALE.

Bedding Calceolarias.

WITH many readers, the bedding calceolarias which bear yellow, brown and bicolor flowers are still favourites and growers find it by no means difficult to carry a stock of plants over the winter, from year to year. An ordinary garden frame serves for this quite well; cuttings root in this soon after they are inserted and, with a minimum of care, pass the winter in safety. Now, plants in the frame begin to grow early in the year and tend to become rapidly overcrowded, to their detriment, it must be admitted; moreover, in a crowded state they do not branch out well and they tend to throw but one or two feeble shoots after they are bedded out in summer. As they are fairly hardy, by far the best plan is to board off a corner sheltered from cold winds about this time and to plant them in this, giving them lots of room. Should bad weather come along, simply lay branches or poles across this frame and put mats over them for a few days; otherwise they are quite safe here. Ten days or a fortnight after they are planted out in this rude frame, but only when evidence of growth is noticeable, pinch every shoot out; this will result in bushy plants in a month's time with shoots on all sides, plants which will become a mass of bloom shortly after they are planted out and which will continue to flower in like manner all season. I cannot over emphasise the benefits of this method; plants retained in the frame are much inferior, liable to damp off or to suffer from green fly and they never bloom so well. When transplanting, work some leaf-mould or a little manure into the soil; this encourages the formation of a mass of fibrous roots which enable the calceolaria to resist drought better than any other bedding plant. Amateurs who buy their plants between this and June will find little variety nowadays. Among the best sorts to grow are Cloth of Gold; Canariensis, primrose yellow; Bijou and Yellow Bijou, dwarfs; amplexicaulis, the old lemon yellow; Golden Gem and the deep browns or reds, Crimson Queen, Sultan, Prince of Wales and The Hero. The white, alba, is seldom seen, but it is well worth a place in clean country districts. Gladstone is a fine bicolor, its leaves are soft and more tender than the others, but the blossom spikes are really fine. —H. AITKEN.

Cucumbers Just Now.

SEEDLINGS will now be ready for permanent quarters in the greenhouse and beds may be made up for them in a suitable place; it is most essential that those beds be made up a day or two in advance of planting, in order to let the compost become thoroughly warmed up. Old turfy loam is generally used; to this is added one quarter of well decayed manure or a pint of hop manure per plant. The stuff, well mixed, is placed *in situ* with due consideration to efficient and good drainage; only two gallons or so are mounded up for each plant, more soil being added as the roots permeate what is already there. Plant the seedlings in mounds or, if seed is to be used, sow two in each place. Maintain a temperature which never falls below 60 degrees, syringe regularly and freely, keep a damp atmosphere and all will be well. Let the main shoot grow well up, then stop and train the laterals on either side; from the laterals, sub-laterals carrying fruit will soon spring. Add soil to the plants as the roots grow through that already there and give liquid feeding when the first fruits begin to form. At this time, also, sow seed for frame cucumbers. It is unwise for anyone without experience to begin frame cucumbers too early, but, if seed is sown now, plants will be ready in good time. Later on, the plants will be planted in the frame over hot-bed material, sufficient to give a good and lasting heat, and by that time the weather will be so far advanced that the grower has no great difficulty with the culture of the plants.—H.

CUCUMBERS PLANTED OUT IN A COLD FRAME AFTER RAISING FROM SEED SOWN NOW.

If all three plants grow well, one should be removed later on.

Two Popular Greenhouse Primulas.

EVERYONE is agreed that Primula obconica and P. malacoides are fine greenhouse plants and particularly useful in winter when stocks of flowering subjects are very low. In order to have first-class plants for mid-winter bloom seed may be sown very soon; it can, of course, be sown from now onwards until the end of May, but I find the earlier sowings invariably more successful. The seed is sown in a well drained seed pan filled with a porous, friable compost; a thin covering of sand or sifted soil is placed on top and the pan is then stood in a kindly corner, not too near the pipes. The seedlings may not come up for some three weeks; from the first, however, keep these seedlings near the glass, and not too warm. In due course, transplant into pots or pans, 2in. apart, and when the plants are well established get them into the frame; grow them there all summer, potting on first into 3in. pots and finally into 5in. pots, a little manure being added to the compost in each case. One great point to note is that they are given free ventilation; shade from strong sunshine may also be necessary and water, of course, must be given daily. It is most essential that good seed be obtained; after all, comparatively few plants may serve, so that the very best is distinctly advisable. Particularly in the malacoides species must the "newest" be ordered, like Dwarf Eclipse, Courtland's Seedling (pink), Superba (red) and good "doubles." Named varieties of obconica are also desirable and the newer hybrid Eureka must not be overlooked.—H. H.

Present Treatment of Forced Bulbs and Plants.

WHEN the bulbs and the various kinds of forced plants have done their part in the supply of early flowers, they are sometimes much neglected. Some cultivators regard forced plants as not worth troubling about; but, with a few exceptions, all may be made to serve again. Hyacinths, tulips and narcissi are the principle bulbs to take care of now. Directly they are removed from the forcing house to cooler quarters the soil must be kept drier, but not too dry, until the foliage has begun to turn very yellow and to shrivel. Then withhold water altogether and keep the bulbs, still in their soil, in a dry place until late in June or in July, when they should be replanted in prepared borders somewhere in the vegetable garden or reserve garden. If left there undisturbed for two years, they will again begin to yield a good harvest of flowers. Spiraeas, deutzias and similar plants may be treated in the same way; and lily of the valley may, with advantage, be planted in a cool north border. Azaleas, rhododendrons, deutzias and other plants that are to be repotted should be retained in the warm house and be duly repotted, afterwards being carefully watered and syringed until the new shoots are almost fully grown. Then gradually harden them and finally place them on slates, tiles or ashes in a cool position facing north, leaving them there until the early part of September.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

FEBRUARY in the north belied its reputation as a bad weather month, and even the adage familiar to readers north of the Tweed that "as the day lengthens the cauld strengthens" lost its meaning. The prevailing conditions could hardly be described as seasonable, for there were occasional mild spells during which the minimum day temperature did not fall below 37 degrees. While the genial atmosphere has had a quickening influence on bud and blossom, it did not favour the beginning of spring operations in the garden, as the ground remained heavy and sodden, especially in those inland districts where the soil is of a loamy clay composition. What is needed at the moment is a short period of drying northerly winds that will make the soil workable and thus enable those amateurs who do not practice early winter tillage to proceed with the essential work of digging and manuring.

Meantime the gardener who is in possession of a greenhouse or frame need not remain idle, for there is much that can be done in the way of striking cuttings of dahlias and chrysanthemums, and the sowing of popular bedding subjects such as asters, stocks, antirrhinums and an endless variety of half-hardy annuals, while the amateur who appreciates the value of vegetables in early summer should make a small sowing of parsley, lettuce, onion and peas, as all these favourites of the kitchen garden transplant readily. Any spare room in the frame may be devoted to cauliflower, cabbage and Brussels sprouts.

When visiting the garden of a successful exhibitor of vegetables the other day I was surprised to find a large collection of 2lb. glass jam jars and a goodly number of bottles such as are used in a confectioner's shop stored carefully in an outhouse. These, I was informed, were used as a substitute for the cloche in the raising of parsnips for competition purposes. The method of culture was very simple. Seeds are sown sparsely in pots of sand and allowed to germinate on the surface without any covering of sand or soil. By means of an iron crowbar a series of holes in rows are made in a piece of ground that was manured for a previous crop last year, each hole measuring 6ins. diameter on the surface and tapering down to the thickness of the instrument at the bottom. The holes are filled to within 1½ins. of the top with a specially prepared compost of leaf-soil, sand and well decayed manure in the proportion of three parts of the former to one of the latter, thoroughly mixed and broken up. When germination has taken place in ten to twelve days' time each individual seed is transferred from the pot to the hole, where it is laid on a thin layer of sand and covered with the same material. A glass jar is then placed over each hole and is allowed to remain until growth necessitates their removal. Feeding is never done from the surface of the holes, but at the side of the rows some distance from the plants.

Cut sets *versus* whole tubers is a question that one hears eagerly discussed by potato growers at this season. The point at issue, of course, is the relation of the particular seed to the weight of the crop. While the popular view favours the planting of the complete tuber, it may interest readers to learn that in a series of experiments carried out by a Scotch firm the results showed very little difference in the yield of the respective crops. In the case of the main crop varieties it was a case of six of the one to half a dozen of the other, but most of the growers of early potatoes who raise Epicure on a large scale prefer the whole tubers for sprouting in boxes. The ideal seed should approximate to the size of a hen's egg, but it is a not uncommon practice to halve tubers of larger dimensions.

At the recent meeting of the Royal Caledonian Horticultural Society a member courageously condemned the dahlia because of its lack of fragrance and also on the ground that, as it was liable to be cut down by early frost in a single night, the flowering period was very uncertain. These points of view are admittedly defects, but they have not affected the popularity of the dahlia as a decorative garden plant, for it is cultivated to-day on a scale that is unprecedented. The collarette and the dwarf bedding variety Coltness Gem are held in universal esteem, and trade growers are increasing their stocks by tens of thousands each successive year. The advent of the Star and the Charm forms created additional interest in the culture of the dahlia, and the creation of a new race by Mr. Unwin is suggestive of great possibilities. In the crossing of Coltness Gem with varieties of the Charm type the habit of the former has been combined with the pretty colours and semi-double form of the latter. Seven specimens varying in growth from 15ins. to 20ins. are being distributed this season. And these are certain to prove a popular addition to our modern dahlia strains.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Treatment of Apple Scab.

The most serious fungus disease of the apple and pear is what is commonly called scab, or black spot, caused by Fusicladium dentricticum and F. pyrinum. The method of attack by both pests and the appearance of attacked fruit are very similar, and for all practical purposes they may be regarded as one. These are diseases that can be prevented, but, once they get established, they cannot be cured without destroying the leaves and fruit. I have tried many remedies with varying results, but I have found the following treatment the most satisfactory: 2lb. of copper sulphate dissolved in 40 gallons of water, applied in spring before the buds begin to open, followed by a light spraying of Burgundy mixture; 2lb. to 3lb. of copper sulphate and 4½lb. and 6¾lb. of soda in 20 gallons and 30 gallons of water respectively, applied just before the flowers open or as soon as possible after all the petals have fallen. Carefully applied, you can laugh at black spot. As soda might vary, it would be safer to use testing paper for the Burgundy mixture: if it turns pink it will be safe; if it remains white, add more soda.—R. C.

Stunted Hyacinths.

It frequently happens that hyacinth stems are very short, giving the plants a stunted look. In such cases it is a good plan to make some paper cones (with brown paper preferably); put these over the plants and cut off the tops of the cones, so that medium sized, round holes are formed. The stems will be drawn up to the light entering these holes, and when the blooms have been raised well above the leaves, the cones may be removed.—J. L.

Starting Begonias Without Heat.

For those who wish to have begonias blooming in the garden early in the summer, but have no heat in which to start them, it is well to commence them indoors at once Procure a shallow box, pierce numerous holes in the bottom and cover with plenty of clean drainage. Fill with rich soil well watered. Begonias thrive best in damp, well manured ground. Place the tubers firmly in the soil and cover box with glass, preferably "Vita" glass because of its beneficial effect. Place in a sunny window in a room which is always kept at a good temperature, water regularly and avoid draughts. As the plants shoot up, the glass can be gradually raised by placing small and then larger stones at each corner. By May they ought to be in bud and ready to plant out.—E. M. M.

How to Insure Plants Against Slugs.

To be absolutely sure of keeping slugs away from a valuable plant, say a very expensive new delphinium, take a piece of old thick felt or similar stuff, cut it into strips 1in. broad, surround your plants or beds with these strips and soak the latter with petrol. Repeat the soaking in dry weather every week, in damp weather the petrol will retain its effect even two weeks after soaking. Never a slug will try to pass the petrol rings. I use this method especially on beds of young delphiniums of which slugs are very fond. Thus I saved fully 100 per cent. of my seedling plants in the past three years. The remedy is inexpensive and the petrol easily poured from a tin can having a slender spout, while rain does not diminish the effectiveness of this treatment.—M. W.

Early Flowers for House Decoration.

Cut off branches of lilac, etc., with good fat buds showing just now. Place the branches in jars of water, with a little charcoal, to keep the water sweet. Put the jars in a dark warm cupboard. Forget them for a few weeks. Then gradually harden to light and air, when there will be a nice bunch of blossoms long before they appear on the trees. Lilac, sloe blossom and flowering currant can be treated successfully in this way and other shrubs would probably respond to this treatment.—M. A.

Sowing Onions.

Most people sow their spring onions too thickly, with the result that when thinned the onion fly starts to work. My plan is to sow the main crop so that no thinning is required. This is done by mixing the seed with double the quantity of sifted soil or sand and then sow in the ordinary way, ignoring the fact that you have mixed anything with the seed. I find the onions generally come about right without any thinning and are large enough for general use.—F. W. D.

Ryders

GLADIOLUS PRIMULINUS

THE widespread demand last season for Ryders Gladiolus Primulinus proves beyond question the immense popularity of these beautiful varieties, which originated in South Africa. This season we offer for the first time some wonderful new colours of unsurpassed brilliance and richness. Among them will be found the "Firefly," a vivid glowing crimson; "Snowdrift," the purest white; and "Sunset," giving all the majestic tints and shadings of a September sunset. These are included in collections 9349-9351.

ORDER THESE SPECIAL COLLECTIONS DIRECT BY POST:—

Collection No. 9349—12 kinds for 7/6
Collection No. 9351—3 Bulbs of each of 12 varieties 21/-

SPECIAL COLLECTIONS OF PRIMULINUS HYBRIDS.

In order to obtain the most effective grouping of colours, many gardeners prefer to leave the selection to our experts, whose knowledge enables them to include in even the most modest collection just those colours that will, when in full bloom, produce the most striking results. To meet this wish we offer a splendid mixture, containing every possible shade of colour. 12 for **2/6** 50 for **8/6** 25 for **4/6** 100 for **16/-**

NOTE:—The collections offered here are taken from the 1927 Catalogue and may be ordered direct from this advertisement. Care must be taken to give the correct Catalogue Number, and all orders must be accompanied by remittance.

RYDERS 1927 CATALOGUE.

Every gardener, before planning his 1927 garden, should possess this wonderful book of THE BEST QUALITY flower and vegetable seeds sold at the economical 2d. packets. Simply send a post card with your name and address plainly written and this 104 page catalogue will be sent free by return of post. Address to—

LABELS.—Patent metal, so simple to write by a nail; can't fade or break. Trial offer; 100 assorted with 50 stakes, 50 tie wires, 1 pocket nail, 10/- free. Samples 1½d The R.H.S. use them. Lists.—WEBSTER'S, Witheridge, Devon

BUSHELS OF LABELS bought with names on are wasted. You write Webster's by nail on the spot to hang, push in, or up on stakes, for rockery, pot frame, rose fruit. 20 sizes 4/9 up., free.—WEBSTER'S, Witheridge, Devon.

YORK STONE PAVING, for Garden Paths and lily ponds; rectangular or crazy for rustic work; steps and wall coping; rockery.—GEO. VINT AND BROS., Stone Merchants, Idle, Bradford.

LITTLE MUNDEN NURSERY, DANE END, WARE.—Spring Planting, Hardy Herbaceous Plants. Low prices. Splendid value. Catalogue sent post free.

PENTSTEMON SOUTHGATE GEM, strong healthy plants, 4/- per doz., post free. SAM MALLINSON, Rufford Road, Halifax.

SHRUBS are becoming more and more the fashion in gardening. "Shrubs for Amateurs," Mr. W. J. Bean's new book, is the best on the subject at a reasonable price. 5/- net. Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

A healthy diet

For plants and vegetables, and for fruit trees, there is nothing like XL ALL Fertiliser as a general promoter of lusty health and vigorous growth. A sound, well balanced food. Of all nurserymen, seedsmen and florists.

XL ALL FERTILIZER

G. H. RICHARDS LTD.
234, Borough High Street, London, S.E.1
R. 263. Monomark: BCM/XLALL.

Please mention THE GARDEN *when writing.*

DUTCH STRAWBERRY PLANTS
(JACUNDA), 17/- per 1,000, £7 per 10,000. Sort and q guaranteed; f.o.b. Hook of Holland.—G. HOMMES, 70A, Grove, New Malden, Surrey.

NEW CHRYSANTHEMUMS.—List of Novelties now ready, also Catalogue of 700 varieties. specialities—Dahlias, Pelargoniums (Show), Zonal Pelargon Fuchsias, etc.—J. W. COLE AND SON, Westwood Nur Peterborough

A GARDEN EVER IN BLOOM will be y if you plant now, for summer: Campanulas from 4/-, Cor 3/-, Erigeron 4/-, Gaillardia 3/-, Genm 4/-, Lupinus 3/-, 3/-, Pyrethrum 3/-. For Autumn: Asters 5/6, Helenius Phlox 4/6, Rudbeckia 3/-, Tradescantia 4/6. For W Helleborus niger 6/-, Iris stylosa 4/6 per doz.; 9d. extra for c below 10/-, for carriage. Fully illustrated lists of these hundreds of other guaranteed strong and hardy plants —H. POLLARD NURSERIES, Evesham.

TANNED GARDEN NETTING.—Small m 25yds. x 1yd., 2/-; 25 x 2, 4/-; 40 x 1, 3/3; 40 x 2, 40 x 3, 9/9. Measured mesh closed. Special Pea N supplied. Tennis Nets from 8/-. Carriage paid. Co our netting with others. Sports lists and samples f GALLOP, Net Manufacturer, Hastings.

GARDEN NETS.—Best tanned, small m 25yds. by 1yd., 2/-; 25 by 2, 4/-; 25 by 3, 6/-; 25 by 4 carriage paid. Satisfaction guaranteed. Tennis nets. S nets for tennis boundary. Pea training nets, etc. List samples free.—G. JARRETT, Netmaker, Rye.

MASKELL'S HOP MANURE.—Best sub tute for Stable Manure. 56lb., 4/-; 1cwt., 6/-; 2cwt., 4cwt., 20/-. Times Guano, the all-round Fertiliser, 56lb., 1cwt., 8/6. Special Potato Manure, 56lb., 6/6; 1cwt., Ground Garden Lime, 56lb., 4/-; 1cwt., 6/-; in bags, all ca paid. All Fertilisers, etc., supplied. Booklets free.—MASK LIMITED, Dirleton Road, West Ham, E.15.

A CATALOGUE of gardening books be sent free on application to "COUNTRY LIFE," LIM 20, Tavistock Street, Covent Garden, W.C.2.

CHEAP GOVERNMENT WIRE! ! !—I for training fruit trees, peas, beans, hops, arches, greenho tomatoes, logans, tying, fencing, etc. Strong, flexible, stranded and waterproof covered. Several thicknesses 19/6 per mile (full 1,760yds.). Small lots quoted. Post to-day for free samples and list of 300 bargains.—GR GOVERNMENT STORES, 69, Albert Street, Lytham.

PROTECT YOUR SEEDS AND BUDS FR FROST AND BIRDS. Netting, strong small mesh, spe prepared, will not rot, as supplied by us to the Royal Gard 25 sq. yds. for 2/6, any length or width supplied, price in portion; carriage paid. Cheaper kinds kept. Tennis Boun and Pea-training Nets. Lists and samples free.—G AND SONS, Net Works, Rye. Est. 127 years.

NEW AND RARE ALPINES.—Andros Gibetica, Hypericum fragile citrinum, Convolvulus mauritan Oxalis adenophylla, Saxifraga Francis Cade, S. caterhame S. Burseriana sulphurea and many others. Descriptive logue free.—BOWELL AND SKARRATT, Alpine Growers, Che ham.

TUBS FOR SHRUB
WIRE BOUND PATENT. Over prizes. R.H.S. Medal, 1910. No warpin shrinking. In Oak, Beech, Teak, etc. Ha decorative. — Price List from A. FR 28, Goodge Street, London, W.1.

THE GARDEN

VOL. XCI.—No. 2884. MARCH 12, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Making Plants Flower.

EVERY gardener, naturally, wants to secure the free flowering of his plants. Now whether these are in pots or in the border, there are just a few points which are worth bearing in mind and these are of almost universal application.

In a general sense plants that grow with great luxuriance rarely produce an abundance of blossom. Although the point is often forgotten, it is a fact that the flower production on the part of plants is associated with semi-starvation. Examine a flowering plant and it is evident that the blooms are nearly always at the ends of the shoots farthest away from the centres of nutrition. It is also a well known botanical fact that most plants tend to be more floriferous at an early date in rather poor ground than when the soil is very rich. If a specimen is growing in extremely rich soil, a great development of leaves takes place and the time of flowering is deferred and the number of blossoms produced may be below the average.

Sunshine is one of the greatest stimulants in the matter of flower production. There are a few plants which will grow in shaded places, like the foxgloves, the hellebores, etc., but these are really exceptional, for the vast majority of flowering subjects are sun-lovers. It should not be overlooked that a situation which is extremely sunny, like a south border, will often prove so hot that the beauty of the flowers does not last long. Here plants tend to set seed very freely and it is most important to pick off all dead blooms as fast as they appear. Then the display of bloom in a hot position may be much prolonged by keeping the soil in which the plants are growing thoroughly moist.

With pot plants, apart from those which are being forced, a very rapid development is undesirable. A slow, steady growth is much more likely to result in the production of an abundance of flowers and the plant as a whole will be more shapely and compact. The chief causes which induce too quick a growth in pot plants are a high temperature and a position where the light is not sufficiently strong. The remedies consist in getting the plants into a cooler atmosphere and placing them as near to the glass as possible.

Pinching out is a very wise practice in the case of many plants, whether out of doors or under glass. Always one gets more flowers by removing the tips of the leading shoots in the early days and the plan may be followed with advantage in the case of annuals as well as perennials. If this is done when the plants are quite young there is no reason why the flowers should be late in putting in an appearance. The result of this step is seen in the larger production of flowers. The state of the soil in which plants are growing has a marked effect on the extent to which they bloom. On close, heavy land, which is relatively cold, plants are always slow to come into blossom. On light, warm ground all plants will come to the flowering stage at a very much earlier date. Where specially early flowers are desired it is worth while preparing some beds in which the soil is much lighter than that usually recommended for the particular kinds.

Look out for our Special Gladiolus Number next week.

Order your copy early.

The Temple Gardens Exhibition.

ARRANGEMENTS are well in hand for the second annual Gardens Exhibition which is being organised by the London Gardens Guild in conjunction with the *Daily Express*. The dates fixed are September 3rd, 4th and 5th. This exhibition is one of the most unique in the country. No cash prizes are given, but Championship medals and other awards are offered for the best grown flowers in the Greater London area. Replicas of the first-prize gardens in the All-London Garden Championships will be made by several leading firms. Last year 20,000 people visited this exhibition, and this year it is confidently expected that this number will be greatly increased. A feature of the exhibition is a class for corporate displays of flowers from garden societies. Last year twelve societies competed, each filling a space 6ft. by 4ft. with flowers; and this year, with more time to make arrangements, it is expected that this number will be more than doubled. While the Show is strictly devoted to amateurs, a limited amount of space is available for exhibits from trade firms who specialise in various flowers. The Temple Gardens, as readers will know, was the venue of the old R.H.S. shows. It is the most central and beautiful spot in London. Readers can obtain a copy of the schedule on application to the organisers, the London Gardens Guild, 124, Walworth Road, S.E.17.

This Week's Work

Plant border carnations.
Sow leeks, onions, peas, cabbages, carrots and turnips in the kitchen garden.
Trim ivy on walls and prune your shrubs (see page 168).
Finish planting perennials, roses and shrubs as soon as weather permits.
Sow celery in boxes placed in a warm greenhouse.
Place boxes and pots of seed peas in a frame to harden off.
Lift and divide old plants of border chrysanthemums.
Protect wall fruit trees from frost by covering with netting.
Pot up tuberous-rooted begonias which have started into growth.
Plant first early potatoes.

Primulinus Gladioli.

A Flower which Everyone Should Grow.

THE illustration on the front cover of this week's issue is that of a group of primulinus gladioli, one of the most fashionable and certainly one of the most attractive of our modern flowers. It is only since the war that this race of hybrids has been developed to any great extent with the introduction of the species G. primulinus from South Africa some twenty years ago, but during that time they have come to the very forefront of our garden plants. Every year brings new and better varieties of richer and more brilliant colouring, which provide the most effective display in the garden from late July until September. It is safe to say that no flower lends itself for use for decoration indoors better than the gladiolus, and for that reason alone the housewife should see that a border is grown somewhere in the garden for cut flower purposes. The collections offered will be found to cover a wide range of shades, and the amateur would be well advised to purchase early and plant during the next two or three weeks. Our next week's number is one devoted specially to the gladiolus, and in it will be found hints on planting, together with articles on varieties to plant, how to arrange them for display indoors and their value in the garden. Our next week's cover will show the large-flowering varieties, and amateurs should note the difference in habit and flower character between the two races. Both are worth growing.

HARDY AZALEAS FOR PRESENT PLANTING

FOR garden planting we still speak and write of azaleas as distinct from rhododendrons, though botanists unite them in the one genus, rhododendron. The original differences were that the azaleas were leafless in winter and had only five stamens, while rhododendrons were evergreen with, usually, ten stamens in each flower. The introduction of evergreen species with five stamens, Rhododendron (azalea) indica, for example, and the deciduous Rhododendron quinquefolium with ten stamens rendered the botanists' key valueless, and there remained no alternative but to unite them into the one genus, rhododendron. For garden cultivation and planting the name azalea can still be usefully employed to distinguish the deciduous members of this very large family.

Origin.

The present-day race, or races, of hardy garden azaleas are the result of intercrossing several species, the most important being Rh. molle from Japan, Rh. sinense from China, Rh. luteum (syn. flavum) from the Caucasus, and Rh. calendulaceum, Rh. nudiflorum and more recently Rh. occidentale, all from North America. The intercrossing of these wild azaleas from three continents by plant breeders or hybridists has given us a family of hardy flowering shrubs with a wealth of brilliant colours unequalled among deciduous woody plants. A garden of any size can scarcely be considered complete unless azaleas are represented. Certainly they should find a place in shrubbery borders, unless heavily shaded, if the soil is suitable.

Planting.

Though frequently alluded to as peat-loving plants, azaleas will thrive in loamy soils provided there is no perceptible quantity of lime present. The natural soil at Kew, where azaleas thrive so well, is a lime-free sandy loam. It is desirable to add a little leaf-mould and peat when preparing the ground, but it is by no means a necessity. Should lime be present in one's garden soil, it is not a difficult matter to remove the existing soil and prepare stations for the azaleas, but before doing this find out if there are any rhododendrons growing in neighbouring gardens. So many flower-lovers only associate azaleas with peat soils, and do not attempt their cultivation because the soil of their garden is loam.

For New Gardens.

Readers planning and planting new gardens should include azaleas among the desirable shrubs to cultivate. It is very noticeable how well azaleas and rhododendrons thrive in most virgin turfy soils. We may find they do not thrive in the soil of an old garden, not because it originally contained lime, but through chalk or lime being added for crops over a period of years.

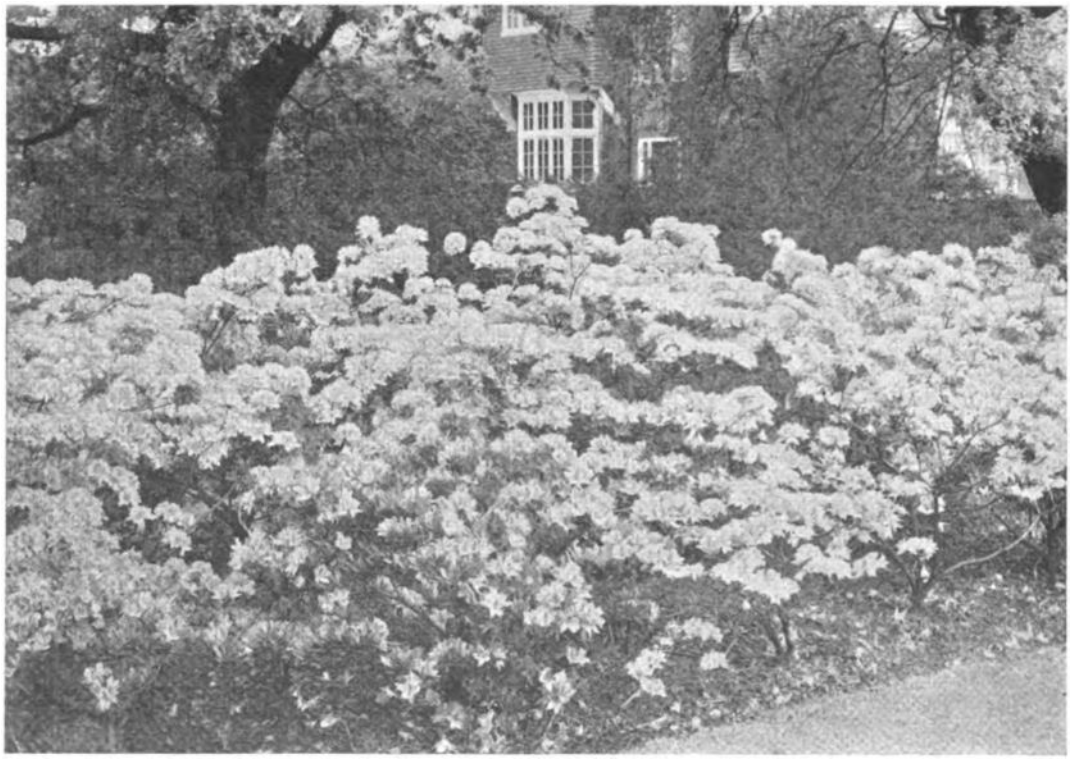
Select light positions for azaleas. A fair amount of sun is helpful to ripen the young growths and develop flower-buds, but I have seen plenty of azaleas thriving under a north wall where they got plenty of light. The two extremes to avoid when planting azaleas are dark shaded positions and very hot, dry, sunny conditions. Azaleas have a liking for a moist soil, not water-logged by any means, but damp ground to keep the roots cool during the hot days from May to September. A mulching of decaying leaf-mould is very beneficial to azaleas applied during May. A bale of peat-moss is quite a good asset in the cultivation of azaleas both to dig in when planting and used in about equal quantities with leaf-mould for mulching. It must be the new peat-moss as imported in bales. Used material from stables will do more harm than good to the azalea roots.

Propagation.

The named varieties of hybrid azaleas are increased by layering, grafting and cuttings. Except for the interest attached to the propagation of one's own plants it is scarcely worth while in small gardens.

Although hybrid azaleas do not come true to the colour of the parent plant when raised from seeds, it is very interesting work. Gather seeds from the best varieties only. While some of the seedlings will vary considerably from the parent plant, others may closely resemble it, and there is always the possibility of raising varieties which are an improvement on the parent.

IN A SMALL FORMAL GARDEN AZALEAS SHOULD BE PLANTED HERE AND THERE ALONG THE PATH FOR COLOUR EFFECT.



AZALEAS ARE ESPECIALLY SUITABLE FOR FURNISHING PATCHES OF COLOUR IN HALF-SHADY BORDERS. *This is an illustration of a bed flourishing in a garden in a London suburb.*

Digitized by Google

Azaleas are among the easiest shrubs to transplant successfully. With masses of fibrous roots at the base they move with firm balls of soil attached. The planting season may extend from November to March whenever the soil and weather conditions are favourable.

It is very desirable to remove the clusters of flower-stalks as soon as the blooms fade and fall. Unless this is done most sorts develop seedpods, which absorb most of the plant growth, whereas it should rightly go in the development of new growth and flower-buds for the following year.

The gorgeous flaming colours of azaleas, though distinct to the eye, are impossible to describe accurately on paper. There are shades of red, orange and yellow, also white or cream, with pinks and rosy purples. All give a wealth of blossom and many are delightfully fragrant.

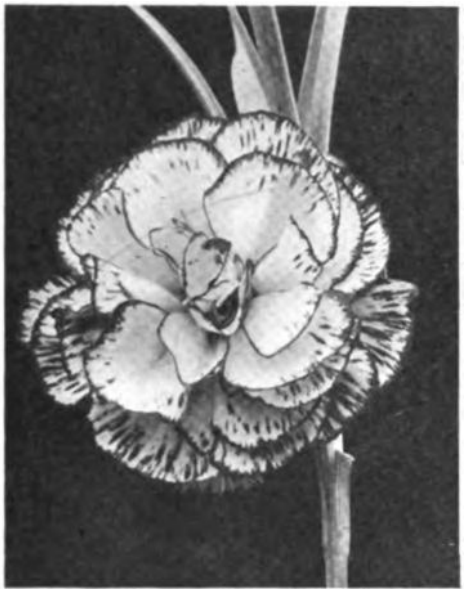
Among a host of varieties from which to select no two growers would agree in the selection of the best dozen. The following twelve, chosen as covering a wide range of colour, are among the most free-flowering sorts and obtainable at reasonable prices: Anthony Koster, golden yellow; coccinea speciosa, orange flame; Daviesii, creamy white; Gloria Mundi, orange vermilion; Grandeur Triomphant, cherry rose; Ignea Nova, carmine flushed orange; J. C. van Thol, red; Nancy Waterer, Indian yellow; Rio des Belges, peach rose; Unique, reddish orange; T. J. Seidel, deep salmon; and Mrs. L. J. Endtz, clear yellow. A. O.

CARNATIONS FOR THE BORDER

There are now many fine varieties of good colour and habit to be had among hardy Carnations, and a few should be included in this year's garden display. Planting can be done this month.

THE first quarter of the twentieth century has seen no less progress in the realm of horticulture than in that of science. The introduction of new and improved varieties of roses, sweet peas, dahlias and chrysanthemums, their general adoption by the gardening community, and the interest evinced at the exhibitions and shows are pleasing symptoms of increased and increasing activity.

The steady stream of exquisite novelties that has emanated from the small but select number of hardy border carnation raisers confutes any suggestion of inertia in this branch of horticulture. But the untiring efforts of the two societies that are exclusively devoted to the fostering of its interests—the Southern Section of the National Carnation and Picotee Society with London as centre and the National Society, Northern Section, with headquarters in Sheffield—and the obvious merits of the border carnation itself have failed to serve as stimuli to the well deserved popular fancy.



PALADIN, A YELLOW GROUND FANCY. GORDON DOUGLAS, A GOOD CRIMSON.
Two fine garden varieties.

While it is true that most gardens contain specimens of the border carnation, it is equally true that it does not command that individual attention, created by the desire to excel, bestowed upon no more worthy subjects. Mankind is disposed to expend its energy in the quest of those things that are difficult to acquire, and it is inclined to depreciate those things that are accessible. Thus the border carnation, thoroughly acclimatised, perfectly hardy and easy to cultivate has come to be regarded as inferior to those garden plants that demand greater skill and more careful nursing.

This is truly deplorable, for the border carnation is unique as a summer-flowering plant, and it is without its peer as a cut bloom for decorative purposes. A true perennial, free flowering in its second season, with blooms of remarkable longevity, embellished with perpetual glaucous foliage, it is worthy of a selected and prominent position in the border of the most exacting gardener.

Plants that have been derived from the layers taken from the previous year's healthy stock are regarded as being the most satisfactory. Though autumn planting is recommended, early spring planting in some localities and under certain conditions may be more conducive to success. Ineffectual drainage aggravated by excessive rainfall is liable to give rise to adverse soil conditions, and where this state prevails spring planting is advocated. Firmly planted out so as to allow 14ins. or 15ins. between each pair of plants in a raised bed that has been duly cultivated, enriched with old manure and freely limed in season, each plant may be expected to give a choice bloom upon the leading growth, with a possibility of side blooms in the later season. Judicious pruning or layering of any side growth that is disposed to straggle in the late summer will assist in the formation of a compact plant capable of bearing a profusion of flowers in the second season.

BOOKHAM SALMON, SALMON PINK.
One of the finest of all hardy border carnations.

Split calyces are a feature of old and neglected carnations, but there are now many varieties that are virtually proof against this weakness. When this tendency asserts itself in such varieties it may be more frequently traced to improper methods of cultivation and gross feeding with fertilisers than to inherited vice.

The numerous varieties afford wide selection in habit and colour. Those that make a short, sturdy growth are preferable to the tall growers, and the self-colours make a more ready appeal than the fancies. An interesting collection may be made from the following varieties:

Self-colours.—Elaine, white; Mary Murray, yellow; Bookham Rose, rose pink; The King, maroon; Gordon Douglas, crimson; and Bookham Salmon, clear salmon pink.

White-ground Fancy.—Fair Ellen, lightly marked grey; and Mrs. Edmund Charrington, regular lilac stripes.

Yellow-ground Fancy.—Highland Mary, rose pink stripes; Linkman, heavily marked scarlet; Sweet Ann Page, lavender stripes; and Paladin, edged and pencilled purple.

Nondescript Fancy.—James Griggs, lavender grey, banded rose.

As the plea of the servant must necessarily be weaker than the direct appeal of the master, there is confidence in the belief that a few plants acquired upon approbation will be destined to be the nucleus of a comprehensive collection of a future devoted carnationist. J. A. H.

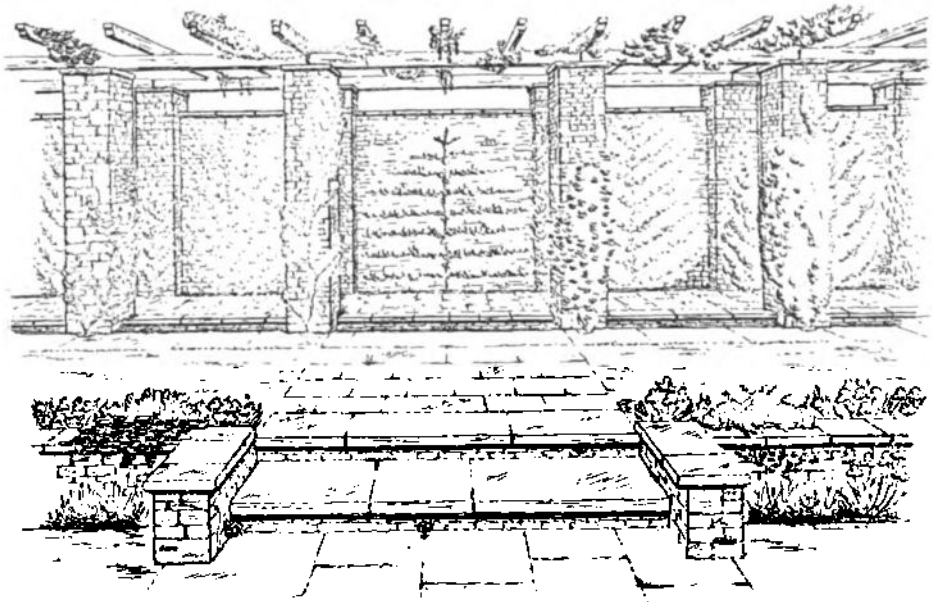
PLANNING THE SMALL GARDEN

Ground contour in the garden is important. Variations in level will be found to make a garden seem larger and will also create a larger area for planting.

WHERE space is little in question, fine garden effects may be achieved "on the flat." The smaller the area we have to treat, the more important it becomes that it should not be left monotonously level. The large garden may rely for form and definition on stately trees and carefully arranged masses of shrub planting, with, very possibly, fine distant scenery. Its smaller counterpart will have no space for striking contour in vegetation, and must very largely rely upon the judicious disposal of the earth at the time when the garden, as such, comes into being.

A garden plot on a level site is necessarily the most difficult to treat, but it must be borne in mind that we do not want sensational differences of level in a little garden; and we can often take advantage of the fact that architects usually place the damp-course some distance above the natural ground level, to form a shallow terrace dominating an otherwise flat garden. And the garden flat itself may be further broken up by the introduction of a sunk garden feature, which need not entail much soil removal.



Indeed, we must, in these cases, be careful to preserve a sense of proportion. In a very small garden, a difference in levels amounting to no more than half a foot may correspond in a large country lay-out to walling several yards high and with elaborate, balustraded two-way steps. Anything in the nature of a well-like effect will reduce the apparent size of a space already small, and give an effect of effort and pretentiousness quite out of keeping with the modest dimensions taken in hand.

We rely on our contouring—and the materials used in the contouring—for much of the form necessary to bring the full beauty out of harmonious colouring; but it also gives us, incidentally, a larger area for planting. And, of course, the plants we utilise for dwarf walling and such-like are of kinds which, in an ordinary flat treatment, we should probably be unable to use. So that we gain in variety of planting form as well as in mere general contour.

Up to a point, then, real variations in level assist us to make a little garden seem larger than it really is, but minor and unnecessary variations always reduce the apparent space available. Two borders with a sunken, roughly walled, metalled path between provide a treatment which appears to occupy less space than would similar borders divided by a simple grass path laid to about mean border level. And the amateur is often astounded at the apparent increase of area brought about by substituting for a gravel path traversing a grass plot a paved one running through it *at turf level*.

The accompanying sketch gives an idea of a treatment very suitable for gardens of strictly limited size, though modifications will, naturally, suggest themselves. We see the outer boundary of a small formal garden in the foreground; a narrow border below the retaining wall, and another immediately above it. A grass path separates this internal treatment from a slightly raised pergola which follows the garden boundary. Such a pergola may be used across the bottom of a suburban garden strip, or, in a garden not too narrow, down one or other side. The pergola as shown cannot be called elaborate, but it is substantial in construction and would only be suitable where the house architecture is likewise of a dignified character. For very small spaces a pergola must necessarily be of rather modest proportions, and uprights partially or wholly carried out in woodwork will be allowable. But any suggestion of "rustic work" should be carefully avoided. A base of stone or brick, if properly proportioned, with squared wooden uprights above, gives a much more architectural character to a pergola than is provided by uprights entirely of wood.

A terraced pergola similar to the one shown is very useful in another way. The combination of a terrace on the garden front of the house with a central sunk garden has already been discussed. But it sometimes happens that the house proper presents but a small frontage to the garden; the remainder of the garden frontage being occupied by a litter of none too sightly outbuildings. In such a case the combination of terrace and pergola is very helpful. Awkward gabled building ends forming part of the back wall of a simple pergola are easily rendered æsthetically innocuous, and may even, in some cases, be made beautiful in themselves. Ugly, bad-coloured brickwork, very possibly badly jointed and (especially in the Midland counties) very likely to be composed of singularly ill-proportioned bricks, should, when plastered and whitened, form quite a pleasing backing to a pergola; but care is, of course necessary in laying out the pillars so that they may at once display what is best worth showing and conceal down-spouts and other obnoxious features. Where down-spouts cannot be hidden, the provision of a good leaden spout-head will revolutionise its appearance. R. V. GIFFARD WOOLLEY.

Single Chrysanthemums for the Border

IT is a far cry to the day when that early flowering Japanese chrysanthemum Mme. Desgrange was first introduced—the early 'seventies—and became the pioneer of outdoor varieties. It is a white sort, still in commerce, and not long afterwards was followed by G. Wermig, a primrose, which for a time held sway as the chief of outdoor varieties. Later, the singles appeared and among the first to be distributed were Mary Anderson, Oscar Wild, Terra Cotta, which did not, however, bloom much before October. They were not received very enthusiastically by those who exhibited, being looked upon as something inferior to the big blooms of Japanese and incurved sorts, which were regarded as only important when size entered into account. Indeed, it was found to be a difficult matter to induce chrysanthemum societies to acknowledge them at all, and in one or two societies with which the writer had to deal, there was much wordy warfare to get the singles included in the schedules. But the public were not long in appreciating singles at their true worth, *viz.*, as flowers suitable for cutting for home decoration, and eventually prejudice was broken down, more especially when those which bloomed early and could be grown in the garden made their *début*. The output in recent years of many single sorts go to show that their popularity is assured, and that they have come to stay, and when one remembers that they can be planted out in May, and can be had in flower from July to October, it is not surprising to learn that they are being grown more every season. Grown outside, one is not concerned so much about the production of large individual blooms, as with quantities of flowers that are peculiarly adapted for cutting for table decoration. They are dainty, and on this account alone are being sought after for planting out in open borders. If it is not always safe to leave clumps in the ground during winter, it is not a difficult matter to lift a few and place under the shelter of a cold frame until spring, and this is all the trouble one need go to. Cuttings can be struck as late as March, and these will make plants that will give abundance of bloom in early autumn. As we know, chrysanthemums are not over-fastidious as to soil when planted in the open: one on the light side, helped with a little manure, suiting them admirably. A sunny position should be given them, and each plant must be well staked.

Among the very many sorts from which one may select to-day in singles, the following are worthy of consideration for planting out of doors:

Golden Gleam, bright yellow, 2½ft.
Papyrus, velvety crimson, 3ft.
Midnight Sun, terra cotta, 3ft.
Delice, bright pink, 3ft.
Nathalie, crushed strawberry, 2ft.
Waterwitch, clear white, 3ft.
Glorious, rich crimson, 2½ft.
Maidenhood, light primrose, 3ft.
September Gem, golden yellow, 3½ft.
Ray of Hope, deep orange, 2½ft.
Doreen Woolman, golden flame, 3½ft.
Stanley Baldwin, wine red, 2ft.
Donald Wells, pure white on long stems, 3ft.
Kitty Riches, rich pink sprays, 3ft.

As will be seen, most of the above are dwarf in habit and are specially suitable for border growing. W. LINDERS LEA.

THE BUSY MAN'S PAGE

Thinning Herbaceous Plants.

WHERE nothing in the way of lifting and dividing has been carried out in the case of Michaelmas daisies, and other occupants of the herbaceous border, a certain amount of thinning out is strongly to be advised. During March most of the clumps will have sent up shoots to the height of a few inches and it is a great mistake to allow all these to develop. It will suffice if from four to six of the strongest are left to each plant. These will finally branch out with great vigour and, in the end, give a far better display of first-rate flowers than would be secured were the whole of the shoots allowed to develop at their own sweet will. Growers who have never tried this plan before will be astonished at the good results which follow.

Fertilisers for Roses.

ALL roses must be well fed in order to keep them at A1 standard and town dwellers who cannot get good natural manure may feel the need of some guidance. Of necessity, they must rely on artificials; these, though not a permanent substitute for organic manures, are very satisfactory, but must never be overdone. Best of all are what might be called semi-natural manures; hop manure is one of these, but a good brand like the well known Wakeley's, should always be insisted on—a good hop manure contains hop refuse and a scientific admixture of the correct artificial fertilisers. Next in order might come bone dust; bone meal may be too coarse to tell fully the first season, but bone flour or bone dust is very good, a quarter pound per border rose. Blood fertiliser, guano and fish guano may be applied at about the same rate, or the chemically-inclined reader may mix up 7lb. good super, 3½lb. sulphate of ammonia, 2lb. steamed bone flour and 2lb. sulphate of potash, applying this at 2oz. to 3oz. per bush. In all cases the plan advocated is that whereby the ground round the bushes is uniformly enriched; scatter the material evenly on the ground and prick it in with fork or hoe. Again, note that when it is the intention to feed the bushes during summer, less may be applied just now; in light soils it is not advisable to put it all into the ground at once, but to give half now and half about the beginning of June.

AN ASPIDISTRA THAT NEEDS REPOTTING.

Hollyhocks.

ALTHOUGH hardy perennials, hollyhocks may be successfully treated as annuals, providing the seeds are sown in gentle warmth in February. Failing this, a sowing should be made in April or May, when germination can be effected in a cold frame; while they will also germinate in the open border—a fact that is proved by the thousands of self-sown seedlings that appear in many gardens. The drawback of hollyhocks is the fungus disease to which they are subject, but this is not so virulent some years as in others, and even if they lose their lower leaves they are very effective at the back of the herbaceous or ordinary flower border. No doubt the best way with hollyhocks is to raise the plants annually; the result is vigorous, healthy seedlings, which are less susceptible to disease than old plants or those propagated by division or cuttings. The double-flowered varieties can be raised from seeds, so there is no need to resort to cuttings, and if seeds of a reliable strain are obtained a large percentage of double flowers may reasonably be expected, while the singles are invariably showy and attractive. From a late spring sowing, sturdy plants will be available by September, when they can be transferred to their flowering stations.

During recent years the single varieties have rapidly increased in favour, and now they can be secured in various shades of pink, red, white, bronze, yellow and rose; while for general purposes a good mixed strain is recommended. Seeds of named varieties are available, such as Golden Beauty, a deep shade of orange; Crimson King; Rose Queen, and others; while the American fringed are quite distinct, being characterised by the beautifully fringed petals. Hollyhocks enjoy a rich, deeply dug soil, and it is always best to arrange them on a border which was manured the previous year.

How to Treat Aspidistras.

THERE comes a time, even with the long-suffering aspidistras, when the plants are very much better for repotting. This should take place in the early spring, loam and sand with some peat and leaf-mould forming a good compost. The soil should be placed in the pot over a good layer of crocks, and worked in among the stout roots as the potting proceeds. The rhizomes, or underground stems, from which the leaves arise, must not be buried deeply, and previous to potting any dead or decaying parts of the stems should be cut away with a sharp knife. When an aspidistra is very large, and the rhizomes are much congested, it is beneficial to divide the plant. The actual work of division should be done, if possible, in a pail of water in order to prevent the undue breaking of many of the roots. If the rhizomes have branched and made two or more leads, they may be cut at the point of division, provided each has roots of its own. These portions of old plants grow with great vigour and often develop a finer type of foliage.

Manuring the Lawn in Spring.

A LAWN must be humoured, or, if it may be put in a different way, different lawns need different treatment. A fertiliser used for any lawn which has fine grasses must, nevertheless, be rich in phosphates and contain a little potash; such a one may be made merely by mixing 6lb. super and 1lb. sulphate of potash, but many simply use a lawn fertiliser, bone dust or fish guano, at some 2oz. to 4oz. per square yard. A lawn on a light soil needs more potash to counteract some of the soil effect of droughts (the quantity should be doubled at least), but, even at this late time, leaf-mould or spent horse manure rubbed through a quarter-inch sieve may be applied and lightly brushed in. A heavy soil, inclined to be sticky and wet on the surface in rain or cracked dry in heat, will derive much benefit from a sandy grit or even fine sifted gritty rubbish; not too much may be applied, however, at this late period. In such a case, carbonate of lime in powder, ground limestone or chalk, may also be applied, lightly, say 4oz. to 6oz. per square yard. A very efficient way to feed a lawn is to spread manure, well broken up, over it; this must be disturbed once a week and after a month the residue is swept up and used for the kitchen garden. Of a tonic nature, so very useful for bringing on grass quickly is sulphate of ammonia; a light dressing, ½oz. per square yard, every six weeks for three dressings, will undoubtedly have a wonderful effect and give a rich, close texture during the whole year. Carbonate of lime and bone meal encourage clover, while sulphate of ammonia eradicates it.

WHEN DEALING WITH A LARGE PLANT IT IS DESIRABLE TO DIVIDE IT INTO TWO OR MORE PIECES.

SHRUBS TO PRUNE NOW

MOST amateurs know that pruning is necessary to attain the best results from ornamental shrubs; but a great deal of doubt is always prevalent as to how and when pruning should be done. The following shrubs are among those which can be pruned from the latter part of February to the middle of March. The method to follow in pruning each one is given.

Ailanthus glandulosa (Tree of Heaven).—When grown for large foliage, cut down to within a few buds of the ground, and only allow one shoot to develop. Given a liberal mulch of farmyard manure, leaves measuring from 3ft. to 4ft. can be produced.

Artemisia Abrotanum (Lad's Love).—Shorten last year's shoots and cut away old wood.

Buddleia variabilis and its varieties.—Cut back last year's shoots to within a few buds of the base. When the new growths appear, select the most vigorous ones and rub off the others, as it is much better to grow a few first-class flower spikes than many inferior ones.

Ceanothus.—The autumn-flowering varieties, such as Gloire de Versailles, should have last year's wood cut hard back. Vigorous growths may be left about 8–12ins., but the weak ones should be removed to within a bud or two of the base.

Cestrum.—Occasionally grown in warmer localities. Cut back last year's wood to within a few buds of the main stem.

Clematis Jackmanii and varieties.—Cut back last year's growth to within a few buds of the base.

C. Viticella and varieties.—Growths made during the summer often die back in winter, and the shoots should be pruned back to healthy buds.

C. lanuginosa.—Does not need such drastic pruning as the above.

Colutea arborescens.—Can be left neat if last year's wood is pruned to within a few buds of the base.

Desmodium.—Semi-shrubs for warmer localities. Cut to ground level or to base of last year's growths.

Eccremocarpus scaber.—Where this has survived the winter, it will need cutting back to a live portion of its stem: this may mean cutting to the ground, but it will probably spring up again from a woody root stock.

Fuchsia.—Where the branches have been killed in winter, cut back to ground level.

Hedera (ivy).—Ivy covering a wall should be clipped back as close as possible with shears.

Hydrangea paniculata and *var. grandiflora.*—If grown for huge flower heads, should be pruned severely. When new growth appears cut this out to a few vigorous shoots. Treat the roots liberally with manure. If very large panicles are not desired, a moderate thinning out of old wood will suffice.

Hypericum calycinum (Rose of Sharon).—Old stems should be clipped almost level with the ground.

H. Moserianum.—Cut out all dead wood and shorten remaining growths to half their length.

Indigofera Gerardiana.—Cut back last year's growth to within a few inches of the ground. If killed back by frost, cut to ground level.

Lespedeza.—Same treatment as indigofera and desmodium.

Lupinus arboreus.—Remove some of the older wood and shorten last year's growths about half-way.

Paulownia imperialis.—If grown for large foliage, treat the same as ailanthus, except that the two best shoots may be grown on for a time instead of one. When growth is established, remove the weaker of the two.

Piptanthus.—Remove old wood and shorten young shoots.

Polygonum baldschuanicum.—If growing in restricted space, some cutting back may be done. Best left alone where room is available.

Rhus typhina.—When grown for large foliage same treatment as ailanthus.

Romneya.—Longer branches will be improved by shortening, and exhausted wood can be cut out. Cut back any growths beyond dead point.

Spiræas.—Such as japonica and its varieties, which produce terminal flower heads on this year's wood, should be cut fairly hard back.

Sambucus (Elder).—When grown for foliage effect—*e.g.*, those with coloured leaves—cut back to within a bud or two of the ground.

Tamarix pentandra.—Cut back last year's shoots to within a few buds of the base.

Tecoma radicans and T. grandiflora.—Cut back last year's shoots to within a few buds of the old wood.

Vitis.—If trained on pergolas, etc., cut back last year's growth to within a bud or two of the main stems. If rambling over a tree it is best left alone.

All pruning operations must be thoroughly done; clean cuts should be made just above a bud, and no ugly snags left to die back. If fairly large branches are cut off, the wounds should be dressed with tar or some similar material. DUNHEVED.

BEGONIAS FOR SUMMER BEDDING

In this article special emphasis is laid on the value of B. multiflora and its many attractive varieties for a bright summer display.

IN my opinion, no type of begonia can compare with the multiflora type for summer bedding, and the same opinion is held by hundreds of visitors who have seen them used in this garden during the past four seasons. The multiflora type is not spoilt by heavy rains, as is often the case with the large-flowered doubles and singles. From the end of May until frost arrives in the autumn there is no break in their flowering period and of colours there is a good selection. I should imagine the variety Le Flamboyant to be the most popular, the colour being a bright iridescent red. Mme. Helene Harms is really a yellow, but if planted in full sun the effect is a more apricot colour, due to the red flower stalk and the pink reverse of the outer row of petals. It is a very excellent variety in all ways. Marguerite Eysser is by far the best of the pink varieties, but, unfortunately, does not make such a good bushy plant as the two previous, but certainly holds its own for wealth of bloom. It is remarkable to see plants of this variety with about half a dozen small leaves flowering so profusely for at least four months. Evelyn Tavenet is a much paler pink, but goes to the other extreme and makes a little too much foliage, but is very free flowering and a dainty and desirable kind.

Ami Jean Bard *the* ideal in habit and floriferousness, and, although described coldly in catalogues as copper yellow, such a description does it injustice. A round bed of this variety, planted in full sunshine, is like a highly coloured peach and cannot fail to charm all who see it. I predict a great future for this variety.

President Savoy is a pale creamy yellow, with the reverse of the outer petals pink, and is splendid from all points of view. A round bed of this variety, banded with a dark blue lobelia, is very charming and novel. Doctor Deluiel is a very uncommon colour in begonias. Individually, the flowers differ but little from Flamboyant, but when grouped together appear to have quite a purple tone, which is rare. The above varieties have all been thoroughly tested by me, and I can strongly recommend them.

So far, I have not seen a good white; the variety Mistress French, which was sent to me for trial, is much too big and heavy. Other varieties I have had on trial are Burgomaster Max, a good grower, but too bricky in colour. Colonel Lausedett, a nice yellow, but with me not equal to Mme Helene Harms. Major Hope, which is strictly not a multiflora, is rather taller than Eysser, with a picotee edge, but is not nearly so free flowering. Fulgurent, a good deep red with erect flower stalk, throwing a big percentage of singles. Guillaume Eysser, another scarlet of the same tone as the well known Geranium Paul Crampell. Mme. G. Bellair is not at all suitable as a bedder, hiding its huge cerise flowers under its ample foliage. Mme. Zelia Roberts and Rouget de L'Isle are two reds of no particular merit. Surpassii Daviesii is after the style of Dr. Deluiel in colour and Fulgurent in habit, and is very charming.

To those readers who are not familiar with this type, I might add that they bear dainty little double and single flowers, some varieties carrying a high percentage of doubles about the size of a Dorothy Perkins rose.

Tubers of most of these varieties may be purchased from various firms, with the exception of Marguerite Eysser, which, so far as I am aware, is unprocurable. Although the initial cost may be higher with this type, as compared with seeds of others, the advantages are many.

Propagation by cuttings is a fruitful source of supply, and, like many other types of begonias, leaves may be used. For cuttings, a start can be made in January, placing a number of tubers in shallow boxes containing leaf-mould and sand, in a forcing house with a night temperature of about 65° Fahr. Do not cover the tubers, but press them into the compost, leaving the tops clear. Spray over several times a day, and keep a moist atmosphere. As soon as growth is big enough to handle, take off as cuttings and insert singly in small pots, plunging same up to the rims in a close case. One good watering in is usually sufficient. So long as the foliage of the cuttings is kept fairly dry, little damping off will occur, and an experienced cultivator should have no difficulty in securing a good strike. As soon as roots show round the edge of the pots, repot into 3in. pots, using a little rotten stable manure in the compost. Cuttings inserted during February and March will require 5in. pots for their finals, and the plants will commence blooming during May.

By the time it is safe to plant them out they will be in full bloom and will continue flowering until cut down by frost. The old tubers will continue to throw up cuttings, which should be taken when ready. If the last batch of cuttings be put in during the first week in May, they will provide plants to furnish the edges of the beds in six weeks time, and, like the bigger plants, will be in bloom. Where sufficient room is available inside, 100 good plants could be obtained from every dozen tubers, and about fifty others which could be grown on in pots or planted out to make bulbs for the following year. F. C. K.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

The Use of the Small Greenhouse.

THERE are probably hundreds of small greenhouses in the back gardens of our towns that are neglected because the owners do not know how to make use of them. March should be the busiest of all seasons for the greenhouse cultivator, for in this month the plants which are to make a good display in the borders all summer must be raised from seed, or started into growth so that the flowering period may commence earlier. If your greenhouse is old and neglected, lose no time in cleaning it up, washing the glass inside and out and spreading fine ashes, or small pebbles on the stages in readiness to receive pot plants. Prepare boxes and pots for seed sowing, scouring the pots inside and out, and then drying them before use. A layer of leaves, or crocks at the bottom of the box will provide drainage, and over this some fine sifted soil, mixed with sand, should be placed, to receive the seeds.

Any of the half hardy annuals can be sown now in a cool greenhouse. Stocks, asters, Phlox Drummondii, verbenas, zinnias, dimorphotheca (Star of the Veldt), kochia (summer cypress) and many others will germinate freely, and if transplanted as soon as they are large enough to handle, either into separate pots or into larger boxes, they will make good sized plants for the summer beds and borders. May is the time to plant them outside in their permanent quarters.

It should not be forgotten that there are many showy annuals which can be grown in pots in the greenhouse during the summer months and which will prevent it from having a bare appearance after the stocks and other half-hardy seedlings are planted out. Torenia, a dwarf plant with numerous pale mauve-flowers, or schizanthus, a fairy like flower in shades of pink, white and amber, could be raised for this purpose. The secret of success is to pot off the seedlings when they are still very small, allowing them plenty of room to develop into strong bushy plants which flower well.

Boxes of seedlings should generally be raised so that they are near to the glass of the greenhouse, otherwise the plants tend to become drawn. Systematic ventilation is half the secret of success in greenhouse management. If you have ventilators opening on both sides, always open the one away from the wind. If only one side is ventilated, as in a lean-to, care must be taken not to allow too much draught when the wind blows strongly against the greenhouse. Stagnant air is bad for seedlings, and some fresh air should be given every day from now onward. Close the ventilators an hour before sundown, to retain the solar heat, and water early in the day.

Moisture must be given at regular intervals. It is best to keep a tank inside the greenhouse filled with water (rainwater drained from the roof, if possible), as this will be always at a suitable temperature for watering the plants. The floor and stages of the greenhouse should be kept moist by syringing or watering, and it is therefore best to make the floor of trellis or laths so that surplus water can drain through and leave the paths dry to walk over.

Delicate seedlings need shading from the bright sunshine. A piece of paper placed over them for a few hours when the sun is brightest is sufficient. Arrange the other plants carefully, giving each as much light as possible, and you are fairly certain to secure a good return for the small trouble you take in utilising your greenhouse.

Repot Fuchsias.

AFTER their winter's rest, fuchsias are showing signs of life. From apparently dead twigs tiny leaves are peeping. Cut back the twigs in the same way as you would prune young roses, leaving three or four buds on each, shake off all old soil, and repot in soil in which leaf-mould and sand have been liberally mixed. Water carefully, and syringe on sunny days.

Begonias in Fibre.

NO other flower is quite so distinctive as the begonia, with its fleshy stems, waxy flowers and curious lop-sided leaves. For continuous blooming it is a close rival to the zonal pelargonium. Not everyone knows that it can be grown quite well as a plant for room decoration. Plant the tubers in bowls, using carbonated fibre. Place the tubers cup-side up in the fibre. Water carefully, and when the little pink shoots appear, press the tubers more deeply into the fibre. On sunny days the plants will benefit by being placed out of doors, but they should always be brought in before the cool of the evening.

Varieties are obtainable in all colours of pink, yellow, white and crimson. The flowers of the double flower type last longer than the single variety. For room culture the lighter shades are preferable.

A succession of flowers can be maintained throughout the summer by the use of a small greenhouse for raising annuals and starting bedding plants.

Grow Your Own Potatoes.

IF the amateur gardeners throughout the country were all told of the enormous number of diseases and parasites which attack the potato, perhaps they would be frightened off the cultivation of this staple crop of the allotment holder. Happily, however, the diseases are neither so bad nor so uncontrollable as they might be. The worst of them all—wart disease—is now under effective control. The amateur would be well advised, however, to plant only those varieties which are recognised as immune to wart disease. Points to remember are to buy reliable seed, and to practise clean cultivation, keeping the land free from weeds, and burning any tops which become affected by blight.

If potatoes used for seed are too large and have to be cut, they should be kept in a dark, cool place for a day after cutting, before being put into the ground. A corky layer then forms over the cut portion, preventing rot. An increased yield is given by potatoes that are set to sprout. For the information of the beginner, the "rose end," which must be put uppermost when the potatoes are sprouting, is the end which shows a collection of "eyes," *i.e.*, the buds of the new shoots. Two shoots to each tuber should be left when the planting is done. It is important to leave a good space between the sets. Three feet between the rows is not too much for main crop potatoes, and the resulting crop will be finer than if the plants are crowded together.

As with most crops, the varieties are legion, and selection depends to some extent on the locality. For general purposes I would recommend the following:

Early.—Witch Hill (immune), a large cropper with shallow eyes. Sharpe's Express, a popular kind of an oval shape.

Second Early.—Great Scot (immune), white and round and a good keeper. Majestic (immune), which produces a good proportion of large tubers.

Late.—The Bishop (immune), a beautiful kidney potato for exhibition, and a good keeper. Golden Wonder (immune), russet skinned and said to be unsurpassed for cooking.

Those who wish for a few coloured potatoes to add variety to the exhibition stands will find useful varieties are "Edzell Blue," and "Mauve Queen."

Sowing Tiny Seeds.

THE size of flower seeds varies considerably, but not according to the size of the mature plant. Snapdragons and begonias have very small seeds, whereas annual lupins have large ones. Small seeds are difficult to sow evenly in pots or boxes. No matter how carefully they are sown the patches of green soon show where the seeds were too thick. Mix the finer seeds with a little dry sand before sowing. Mechanical sowers can now be obtained for sowing seeds evenly. If sowing in boxes or pans always water before sowing, and, after scattering the seed evenly, cover lightly with very fine sifted soil. Each box or pan may be covered with a sheet of glass and piece of brown paper until germination has taken place.

THE FLOWER GARDEN

Herbaceous subjects for late planting. Pyrethrums, Gaillardias and Anchusas for colour in the summer—Red Hot Pokers for brilliance in autumn.

Raising Anchusas from Seed.

Two Good Varieties for Present Sowing in the Open Ground.

THOSE requiring a fine blue perennial for the back of small or the middle of large herbaceous borders should raise a stock of anchusas from seeds. The two which have proved most successful in my hands have been Anchusa italica, a large-flowered Cambridge blue, and A. Dropmore Opal, a pale forget-me-not blue, which has smaller flowers somewhat resembling large forget-me-nots, but paler in colour. Anchusa italica makes a magnificent border plant even in the poorest of soils, growing to a height of 3ft. in such ground and branching out with its flower sprays until it occupies nearly a yard of space. In a well manured border, or if a handful of coarse bone meal has been dug in at the time of planting, the plant will go to a height of 5ft., and require staking with a fairly strong stick, or wind will take advantage of the tree-like formation and rock it out of the straight. The same remarks apply equally to A. Dropmore.

The tendency with those who do not know the plant will be to place them too close to other perennials in the border. They require at least a yard of ground if they are to give of their best. The seedling plants look such puny things, about the size of a healthy primrose plant, which they rather resemble, giving no indication of the giant stems which will rise from their centres the following summer.

They are perfectly easy to raise from seed, requiring no frame or other coddling. The seed is large, and easily handled, which makes it possible to space them in the drills so that each plant will have room to develop without thinning. I have tried sowings in both March and April, and both seem to do equally well in Berkshire. Drills are drawn about an inch deep, and the seeds placed therein at 2in. intervals, lightly covering with the soil which has been removed. A position should be chosen for these drills where it will not matter if those seeds provide a succession of plants over a period of three years, the reason being that it is extremely difficult to get the whole of the plant out of the ground. The anchusa seedling makes a very long tap root which penetrates some distance into the soil, and a portion of this root is almost certain to be left in the ground when the seedling is lifted. This may be 2ft. down, and measure only an inch or so. But, as sure as fate, during the next season that small piece of root will form a splendid plant which will flower prodigiously. I sowed anchusa seed three years ago, and am annually able to replace those which die in the borders from the plants produced by the roots which are inevitably left in the soil.

I am not at all sure why some of my anchusa plants die back each year; the fact remains that they do. Possibly this may be due to my soil being a heavy clay. The more floriferous the plant the more certain is it that it will have flowered itself to death. This is peculiar in face of the fact that the roots of the seedlings in the same soil produce a succession of plants year after year. On digging up these dead plants the root system appears to have rotted away.

The roots of the anchusas are peculiar things, rather like a piece of very dirty black wet thick string, and break very easily. Like the Oriental poppy, any piece of this root seems capable of forming a plant, which makes increase a matter of extreme simplicity. The long tap roots merely require to be cut into inch lengths and inserted in ordinary soil out of doors in the autumn, when a good stock of plants will be available in the following year.

In the herbaceous border it makes a striking note of colour, and is extremely useful when planted near the perennial lupins, as it comes into bloom at a time when the lupins in going out of flower leave rather unsightly blanks in the borders. The plant itself makes very little foliage either close to the ground or on the flowering stems, with the result that the solid mass of bloom is well displayed. Quite a small packet will provide sufficient plants to furnish a large border in the following season, planting out being done in autumn, and further plants will be provided by the broken seedling roots should the original stock die back in the borders.—CLARENCE PONTING.

A SEEDLING OF ANCHUSA ITALICA IN THE FIRST YEAR.

An Accommodating Border Plant.

THE florists' varieties of gaillardias constitute a wonderful series of fine border plants, which are in bloom from July to September, and as they only attain a height of 2ft. to 2½ft., they are well-nigh indispensable for the front part of a herbaceous border. They are among the most gorgeous of hardy perennials, and are well adapted for bold groups, also they are very effective in clumps of three plants. Moreover, they are excellent for cutting purposes, and are most pleasing in vases in the dwelling-house. These delightfully decorative plants require no special treatment in regard to soil, the ordinary root run available in gardens generally will produce blooms of first-rate quality. One that has afforded me great pleasure is The King, a large and showy flower, the long, broad, deep red petals being margined with bright yellow. It possesses a good constitution, and if due attention is paid to cuttings whenever they are available, a healthy stock is soon obtained.

Another fine variety is Lady Rolleston, a soft golden yellow. It is very free-flowering, and a beautiful colour, while the blooms are large and showy. There are other named varieties of equal merit, but to some growers the beautiful unnamed seedlings will appeal. They are sold under the name of G. hybrida. They are most reasonable in price, free flowering, and the colours are usually various shades of crimson and gold. For those who want a good display at small cost the seedlings are strongly recommended. It should be borne in mind, however, that most firms send out flowering examples, and not small specimens as is generally understood when seedlings are referred to.—T. W. B.

Saxifrage Guildford Seedling.

SOME of us who do not like to think ourselves very old can remember when Guildford Seedling was the only truly red-flowered "mossy" saxifrage; to-day their name is legion. The writer must have seen practically every red-flowered "mossy" in commerce, and grown many of the best. Sanguinea superba is fine; so, in a different way, is Pompadour; the older barthoniensis is cheerful, easy and good. Yet, when asked—as I often am nowadays—the name of the best red-flowered "mossy," I always say "Guildford Seedling." This was never a plant of rapid increase, and, doubtless, it is even more "stay-at-home" nowadays than when of recent introduction, but in a rock plant a rampant habit is not in all positions a recommendation. The flower opens a good colour and retains it remarkably well; moreover, the blossoms are always well formed, and the foliage is neat and of a rich dark green, worthy, in fact, to bear comparison with that of the cæspitosa, hypnoides and muscoides varieties.—V. G.

Some Useful Harebells.

THE genus campanula is a large and varied one, but in C. carpatica we have a glorious all-round plant, suitable for a variety of purposes, and one, moreover, that it is easily grown. The type produces erect deep blue flowers more or less funnel-shaped, and the loose panicles attain a height of 9ins., but this will be exceeded where the plants are growing in rich soil. In addition to the type there are a large number of hybrids and varieties, many of which are most exquisite. The form known as alba is pure white, and it is very effective when growing in close proximity to a blue-flowered variety. In White Star we have another white with just a trace of blue in the large saucer-shaped

Digitized by Google

flowers which are about 2ins. across. A very fine form is Riverslea, with large flat clear rich blue flowers, and Isobel is a beautiful dark violet. C. c. pelviformis is a more distinct variety, and not quite so vigorous as those named above, but nevertheless it is very handsome. It bears a profusion of large flowers of a pleasing shade of pale blue.

All the harebells quoted in this note produce a wealth of blossoms from June to September, and they should be grown in full sunshine, although they will also succeed in partial shade. A rich rooting medium is not required, and they will thrive in ordinary garden soil, all being robust and capable of taking care of themselves when planted. They are ideal subjects for the rock garden and walls, while they are quite at home in the front line of the herbaceous border.—CHEPSTOW.

Some Good Pyrethrums.

FROM the end of May to the beginning of July, few plants of the herbaceous border can rival with the so-called pyrethrums as to the richness of flowers. More than seven hundred named horticultural varieties are known to us up to the present day, and each season adds some good ones to this already excessive number. In my judgment one of the best of the pink ones is Eileen May Robinson. For the most part the single or semi-double flowers are of a distinct pinkish colour, scarcely surpassed, so far as I know, by any other among the numerous varieties of pyrethrum roseum. It is as beautiful in the open as in the vase. All the pyrethrums have a great value for cutting purposes.

Among the red ones are two varieties, both decorative and floriferous: Agnes Mary Kelway (at the left of the picture), and Mrs. Bateman Brown. The first is of a vivid rose pink, the second crimson red. The double forms, too, are of great beauty, and their flowers last even longer than those of the single ones. A very good white variety is White Queen Mary, with large snowy white flowers. It seems to be the most commendable of all the white double forms I know. It may be added that from a botanical standpoint these pyrethrums are now referred to the genus chrysanthemum, and are called C. coccinum. This is a species from the Caucasus and Persia, where I met it in meadows like our common ox-eye daisy. C. coccineum is cultivated in France and in California for insect powder. In gardens C. coccineum is also called Pyrethrum hybridum, and there are probably a lot of forms of hybrid origin among the cultivated varieties. —CAMILLO SCHNEIDER.

KNIPHOFIAS WITH THEIR STATELY SPIKES OF ORANGE AND RED FLOWERS.

The Red Hot Pokers.

THIS stately group of lilaceous plants is capable of creating some very fine garden effects, more especially when judicious care is expended upon their effective placing; they will, assuredly, lend an air of distinction to, and, indeed, ennoble, the hardy flower border, and they are never seen to greater advantage than when grouped in isolated positions and with a suitable background. They are particularly beautiful when grouped in front of yews or other coniferous trees, not, of course, immediately in front of these trees, but sufficiently to the fore to display a proper sense of proportion with the general surroundings.

Beds planted with one variety of the larger type are far more telling than are mixed plantings and a grouping of such a one as the old nobilis, 5ft. to 6ft. in height, can be an outstanding ornament of any garden. The smaller kniphofias, such as the gracilis group, are very beautiful for massing on the large rock garden or in the herbaceous border. Of comparatively recent introduction, these small red hot pokers should stimulate an even greater interest than of yore in these noble plants.

Not the least pleasing feature of these plants are the generous tufts of broad grass-like foliage, a splendid foil to the stately spikes of flower; of inestimable value in the late summer and autumn garden, I have known, in a mild season, quite good flowers in evidence during December.

Kniphofias delight in a deep, well drained and rich loam, deeply dug and enriched with some well rotted manure; they may be planted in autumn or in spring, from February to April and when once established, they intensely dislike frequent disturbance. During severe weather or in very cold, exposed situations, it is well, during winter, to afford them some protection in the form of straw, bracken or dry litter. The stock may be increased by careful division of the roots. A good selection of kniphofias should include nobilis, orange scarlet; Uvaria grandiflora, scarlet; Royal Standard, scarlet and yellow; grandis, orange scarlet; C. M. Prichard, rich yellow; aloides maximum, a veritable giant with orange scarlet flowers; corallina, coral red; Tuckii, glaucous foliage and orange scarlet flowers in June; Sulphur Spire; Rufus, yellow and scarlet; and Solfaterre, soft yellow.

The gracilis hybrids grow from 3ft. to 4ft. and flower from July to late autumn; well adapted for the perennial border, they display a wide range of colouring in their small and graceful spikes of flower. Some of the best of this section are Alaska, rich yellow; Victoria, orange yellow; Chrysolora, golden yellow; Daybreak, yellow tipped orange; and Lemon Queen. Macowanii is a lovely species of small growth, producing a profusion of brilliant coral red flowers throughout the summer months.—R. E.

AGNES MARY KELWAY, OF BRIGHT ROSE PINK.

MRS. BATEMAN BROWN, A DEEP CRIMSON VARIETY.

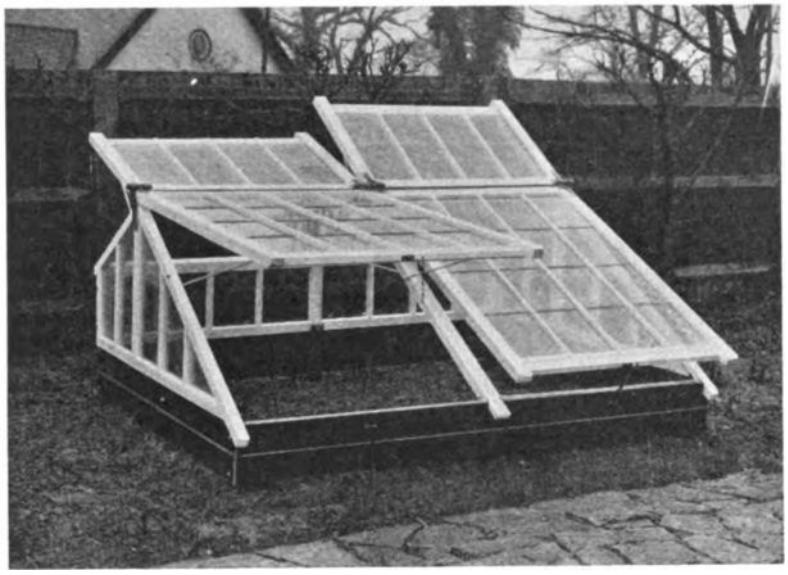
THE COLD FRAME AND ITS USES

No garden is complete without some form of garden frame. There are now types to be obtained suitable for all purposes and for every size of garden. The amateur will find that with the aid of an inexpensive cold frame his gardening duties will become increasingly interesting. In this article these various types are described and their uses discussed, with hints on where to place them and how to manage them throughout the year.

THERE is no doubt that in the upkeep of a garden the cold frame plays a very important part; indeed, it is not an exaggeration to say that this device is almost indispensable. The services which the frame will render are very numerous, although the frame is never heated in any way, and it is always possible to extend its usefulness by the formation of a hot-bed. Even those gardeners whose ambitions do not extend to a glasshouse should certainly establish one or more frames, and never will there be any regrets over the matter. Naturally, the cost of frames to hold a given number of plants compares favourably with the expense of a greenhouse of equal capacity. Then there is no doubt that many kinds of pot plants flourish as well, or even better, in a roomy frame than they do in the larger structure. For the raising of half-hardy plants from seed, the hardening-off of tender subjects prior to planting out, and the growing of cuttings in conjunction with a greenhouse, the frame will prove of great service. Many plants can be kept in the frames up to a certain stage in their growth and then removed to the warmer atmosphere to complete their development. Plants such as primulas, cyclamen and cinerarias might be kept in frames until the late autumn, and this would free the greenhouse for a summer crop of tomatoes or enable it to be used for some other purpose.

A lean-to frame or forcing pit on a brick foundation. When a permanent frame is desired then this type will prove most useful for all general purposes.

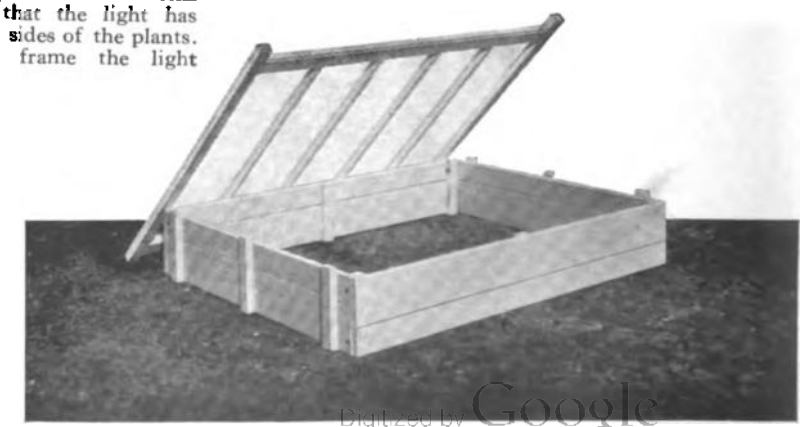


The three-quarter span-roof type of frame can be made with a wood foundation as shown, or built on to a brick base. Easy access can be had on the two sides by means of the hinged lights, which is an advantage. This type is most suited for housing greenhouse plants.

Nowadays frames of almost every conceivable size and pattern are offered to the public. The buyer should bear in mind that, generally speaking, the low-priced articles are rarely satisfactory. Although the frame may be cheap in price, it will certainly be "cheap" in other directions. The wood will be thinly cut and unseasoned, the glass of a light weight, the paint and putty of an inferior nature and so on. Such a frame will soon warp or rot and, while it is in use, the structure will allow serious fluctuations of temperature which will have a very bad effect on the plants grown. Never consider a frame unless it is made of thoroughly well seasoned wood at least 1¼ins. thick—1½ins. is better still. The four sides should be closely fitted together to exclude air and strengthened at the angles inside with upright bars of wood. A flange of wood should be nailed along the outside of the two sides for the same purpose, and the sashes must fit exactly in their places. The lights, which ought not to be less than 2ins. thick, should be glazed with 21 oz. glass.

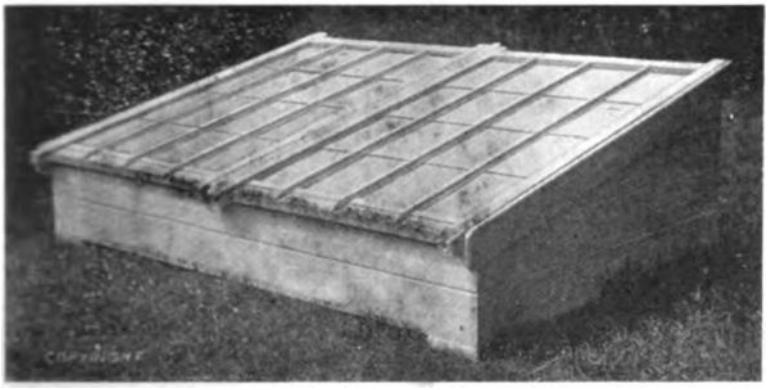
Kinds of Frames.

In a general sense frames fall roughly into two classes—the span-roof and the lean-to. The former type is the more suitable when the frame is for the growing of pot plants, such as cinerarias, begonias, primulas, etc. In the span-roof there will be a greater depth and an additional advantage is that the light has access to both sides of the plants. In a lean-to frame the light enters at one angle and, as plants tend to grow towards the source of light, the symmetry of the specimens is affected. Ventilation is easier in a span-roof frame, for the lights to the windward side may be closed while those to the leeward are opened. The value of the lean-to frame is chiefly in connection with soft young plants which will only be in the structure for a short while. This type, with its comparatively shallow front and back and fairly flat roof, ensures that the plants will be near the glass. In the case of certain plants the maximum of sunshine is very desirable, and a lean-to frame facing full south will ensure this. Again, the coolness of a northern exposure may be desired for the purposes of propagation, and in such cases a lean-to frame, backed against a high wall or fence that keeps away the sun, will provide ideal conditions. Frames which are to remain in one position are much better when set on a brick foundation. On the other hand, there is much to be said in favour of the portable frame, which can be moved about as required to different positions. An excellent type is the two-light lean-to frame. A span-roof frame with two lights on each side is also very handy and useful. A half-way house between the span-roof and the lean-to is the type of frame known as the three-quarter span. One of the illustrations explains the nature of the design. The short span is especially useful for ventilation purposes and, in addition, gives extra height for tall pot plants. There is also the span-roof frame in which the lights turn right over, a most convenient arrangement which the gardener will be quick to appreciate. Of course, where big demands will have to be made on the space in the frames it pays to buy a larger type with, say, six or eight lights. This is arranged so that the lights can be securely fixed open up to 2ft. 6ins. in such



An ideal portable frame for all allotment holders, and one found invaluable in the small garden. It may be used to serve a double purpose—for protecting your plants and raising seedlings. This size is 4ft. 9ins. by 3ft. 9ins.

Digitized by Google



A two-light lean-to frame with sliding lights. This is a useful type, but requires slightly more space for the placing of the lights. The amateur will find this frame serviceable in the raising of all seedlings and cuttings.

a way that work can be easily done underneath.

Position of Frame.

Naturally, it is a good plan to set a frame in an open position, for in nearly all cases the more light the better. Some consideration should be given to the question of shelter from the north and east, and in the placing of the frames advantage may be taken of walls, hedges, fences, etc. Unless a frame is to be used as a hot-bed or for some purposes like the raising of early salads, the floor inside is best covered with beaten cinders. On this the pots, pans and boxes can safely stand, for one can be sure that there will be a free drainage of water. In all cases the distance between the soil and the glass of the frame should never be greater than is just sufficient to accommodate the plants. It is often an excellent plan to raise pots, etc., containing seeds on bricks so that the little plants when they come up may be close to the glass to prevent their being drawn.

Watering and Ventilation Necessary.

Even the smallest frame requires unremitting attention. One of the great things to guard against, no matter what may be grown in the cold frame, is damp, and this is especially so in the early months of the year. Too much watering and too little in the way of ventilation will inevitably lead to that disastrous condition known as "damping-off." This trouble, although due to the attacks of a minute fungus, is usually associated with excessive moisture either in soil or atmosphere. Of course, it goes without saying that the soil in which seeds are sown should be light and that the pots, etc., must have a free drainage. After the sowing of the seed no water need be given for some days providing the soil was in a fairly moist state at the start. In fact, if the frame is kept rather close, as is the best way, until the little plants begin to appear, there should not be the least risk of dryness. Eventually it will be necessary to start watering, and this should always be done in the morning, after which some hours of ventilation are allowed. Avoid wetting the foliage as much as possible, so that the plants will go through the night with dry leaves. In managing a cool frame try to equalise the temperature between the interior of the structure and the open air as much as possible. It is when there is a sharp difference between the two that condensation of moisture takes place on the glass and young plants are soon in great danger. Thus it follows that, apart from very exceptional weather such as we sometimes get in a wintry spring, it is always best to ventilate. When the weather is inclement the lights might only be raised a little and kept open long enough to allow the grass in the frame to clear. In bright weather the frames require a good deal of attention, for if the lights are closed while the sun is shining on them a very unhealthy state of the atmosphere will be created in the frame. At the close of a day it is a mistake to shut up the frame too early, and it is really a good idea to continue some ventilation until nightfall unless the conditions are very bitter.

Wherever there are frames there should also be mats, for if a keen night is anticipated these will be most useful for protective purposes. It is most important that the mats should be dry when they are placed on the lights, as if wet they will convert the frame into a veritable ice house in the event of the frost being severe, as is always possible in an English spring. Of course, sooner or later there will be days when for some hours at least the lights of the frame may be lifted as high as possible or removed altogether. Now and again if owing to cold winds a very free ventilation cannot be allowed, it is not a bad plan to use mats to protect the plants from the strong sunshine which we often experience in March.

How to Guard Against Pests.

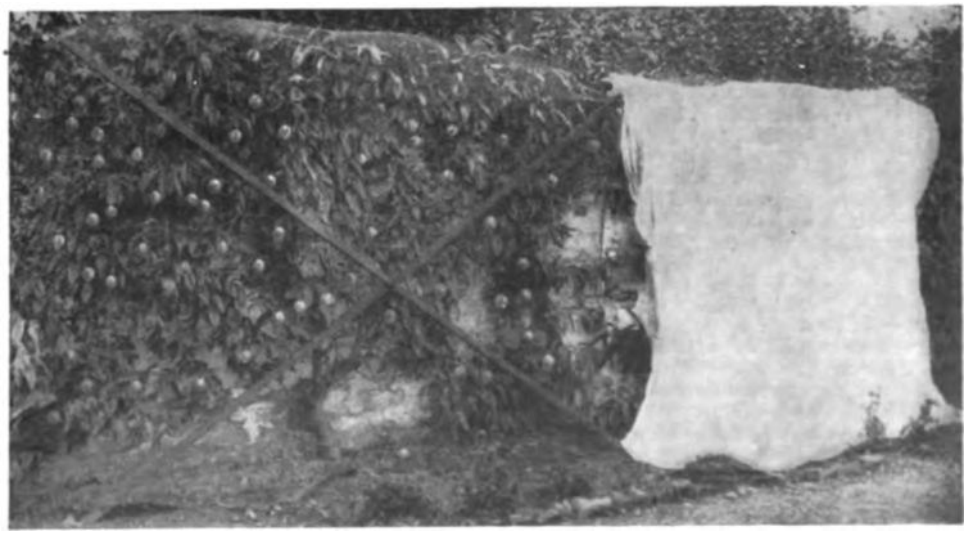
In connection with frames a sharp look-out must always be kept for such pests as slugs, woodlice, etc. No soil should ever be used in a frame unless it has been sterilised by steaming or baking. This will not only destroy the eggs of slugs and kill woodlice, but it will also go a long way towards checking damping-off, for the germs of this fungus, in addition to others, lurk in soil. All pots, pans and boxes employed should be clean. Examine the boxes closely if these are not new, for quite often woodlice creep into the joins, and one or two of these creatures may spoil a promising batch of seedlings in a single night. Even when precautions have been taken a sharp watch should always be kept to make sure that the plants are not in danger of attack. It is an excellent plan to move the pots, etc., about every few days and so expose any possible hiding places of slugs or woodlice.

[We are indebted to Messrs. Boulton and Paul, Messrs. Duncan Tucker and Messrs. Geo. Hayward for the illustrations which accompany this article.—ED.]

PROTECTING FRUIT TREES

THERE are many owners of gardens who have not yet realised that they can now entirely eliminate from all their fruit trees, except the very high ones, the following pests: bullfinches, tits, blackbirds, frosts, cold winds, and wasps, by various appliances which have been recently introduced by Major C. Walker. With these pests eliminated, and insects and disease kept down by the various insecticides and fungicides now available, there is no reason why every average garden should not produce, in even bad seasons, ample fruit of all kinds to keep the house supplied all the year round. The one gap—after the apples are over in March and before the strawberries come in at the end of June—being filled by all the various surplus fruits which should have been bottled.

It will now be necessary to explain how this protection is provided. For wall trees an adjustable framework to fit the size of the tree is covered over with a special frost-proof netting with which a guarantee against 14° of frost is given. This netting absorbs the moisture in the atmosphere and retains the warm air radiating from the wall around the tree. It first protects the buds from the birds and the early blossoms, and when these are set is carried and placed against a late-blooming tree. When danger from cold winds is past, the netting is taken down and used again to protect, first, the early cherries, then the peaches and plums, from birds and wasps, and lastly, the pears from the tits When the fruit commences to ripen, the



AN ADJUSTABLE WALL TREE PROTECTOR PLACED IN POSITION.
A special screen as an additional protection against wasps can also be seen on the right of the picture.

Digitized by Google

wasp screen is pinned over the netting so as to seal the whole tree from these pests.

Until now, we have never had any means by which we could protect a tree growing in the open. This is performed by the bush protector, placed over trees up to 8ft. in fifteen minutes, and with a little adjustment can be used on higher trees. One protector can save several crops in one season by protecting first the buds, then the blossom, and finally fruit; being likewise carried from the early to the late blossom and fruits, so that it should be doing its work from February until October, and therefore will cover its cost in the first year by the fruit it has saved. A wind screen can be tied on to the windward side of the netting; this and the roof are composed of the frost-proof netting and keep off the lighter frosts.

A BUSH FRUIT PROTECTOR PLACED IN POSITION.

This will be found to preserve the crop against injury from attacks by frost and birds.

We finally deal with the small fruits, which are protected by a transferable cage made to any size 6½ft. high, which can first be erected over the strawberries, and when they are over, can be taken down and erected by one man in three hours over either the gooseberries, raspberries and currants, or the culinary peas. Like the protector, it saves at least two crops in one season. The tit feeds her offspring on insects until they leave the nest, and therefore never attacks the earlier crops of peas until the strawberries are over. This cage has innumerable advantages over any other form; it is much cheaper; simple to erect; fruit can be picked in comfort without any removal of nets; is not unsightly like wire and posts, as it is stored when the crop is over, and therefore cannot be wrecked by a snowstorm; it can be reduced in size; entered at any point; and the steel standards which stand as if in cement, can be pulled up with one hand, and will last a lifetime.

A TRANSFERABLE FRUIT CAGE.

Useful for covering bush fruit or protecting strawberries and other low-growing crops.

WHAT OUR READERS SAY

A BLUE ACHIMENES

SIR,—Your correspondent, A. Bulwer, asks the name of the real "blue" achimenes. I believe it to be longiflora, and the white one is longiflora alba. I have grown them both for many years, and consider them about the best varieties I know of. They are described in "The Florist" of 1852. I do not know of any firm offering them.—E. D'OLIER, *Bray, County Wicklow.*

SIR,—Achimenes longiflora major is undoubtedly the plant to which your correspondent, page 143, refers. It is taller than the average achimenes, and has small green leaves and produces large open flowers freely. Under some lights and conditions these have a very blue appearance, not unlike some delphiniums. Years ago, as a journeyman, I had charge of a large collection of these plants, and never missed a chance of seeing others; but the *true* blue achimenes has yet to be raised, *viz.*, anything approaching the real blue of Gentiana verna or phacelia.—J. COMBER.

[We have consulted many catalogues but have failed to find this particular species listed. We suggest, however, that if our correspondent writes to one of our leading nurserymen engaged in the cultivation of greenhouse plants, such as Messrs. Russell of Richmond, the plant may be obtained.—ED.]

CAMPANULA ISOPHYLLA MAYI.

SIR,—With reference to an answer to a correspondent in the issue of THE GARDEN of February 26th, we should like to point out that the campanula referred to is not C. Mayi. There exists much confusion over the name of this plant, and a few notes on its origin may be interesting.

C. Mayi was sent out as a cross between fragilis and isophylla. Soon after its appearance, it was noticed that it was apt to send up variegated shoots and Messrs. Balchin, a South Country firm, soon offered variety Balchiniana, a pretty silver variegated form. We bought it at that time, presumably, from the raiser. Several times since then we have had a variegated form offered us by growers—not knowing of Messrs. Balchin's plant—who had noticed and struck these foliage sports. We still grow the green-leaved form, which is downy leaved, and also the variegated form known as Balchiniana.

It does not seem generally known that all these forms—fragilis, isophylla (blue and white), Mayi, etc.—are quite hardy in a wall or well drained cleft in the rockwork.—J. STORMONTH.

PEAT IN THE GARDEN.

SIR,—While it would be useful to have a definition of what your correspondents, "Dunheved" and "R. H." understand by "peat," their letters raise the larger question of what the term peat, when used by writers on gardening, is intended to cover.

True peat is a substance formed by the action of stagnant water on decayed vegetable matter and is only found in bogs and fens. It is not generally available, and most authorities agree that it is not essential to the well-being of even ericaceous and other "peat-loving" plants.

What in this district, however, is commonly called peat, occurs in two forms—a dark brown, flaky deposit, 2ins. or 3ins. thick, found in woods, especially of beech, oak and birch, which is, I suppose, more properly leaf mould, although distinct in appearance and texture from that obtained by piling leaves in a heap; and a bright brown, soft and fibrous deposit, very light in weight when dry, occurring in old bracken beds, where it may average 8ins. or 9ins. in thickness. Both may be found in dry places, even on sandy uplands, and water—except rain—evidently has nothing to do with their formation. These two substances are extremely valuable in the shrubbery and if they are the peat "Dunheved" has in mind, I quite agree with him that their use is very desirable, to say the least, in the cultivation of rhododendrons and many other shrubs. Like the true peat, they are, of course, acid in character. Perhaps the above correspondents or other readers of your paper can make clear which of these forms is the "peat" we are bidden to use by some writers and to dispense with by others, in the cultivation of peat-loving shrubs and plants.—A. E. F., *Berks.*

EARLY BROAD BEANS.

SIR,—In the issue dated February 19th of THE GARDEN is a short article on the raising of broad beans under glass in order to obtain an early crop. I think I am able to suggest a means by which the labour attending the growing of early crops of broad beans can be reduced and the result be at least equally certain with, probably, even an earlier crop than is possible under the system recommended.

A friend in this village possessing a large garden planted a portion of it with the ordinary farm winter bean, usually fed to pigs and horses. In the following spring he thoughtlessly planted broad beans alongside the field beans, with the result that the bees cross-pollinated the two distinct types.

My attention was called to what should have been broad beans, but which were of varying sizes and shapes, a few being of the form of ordinary broad beans though somewhat smaller. I begged some of these for the purpose of testing their ability to withstand the winter. A few survived over the first winter, which was somewhat severe. The next winter was milder, and fewer were killed off by the frost. The fifth winter was very severe and only two plants came through. I have continued to select the largest beans from the most prolific plants, with the result that in the winter of 1925–26 nearly all the plants withstood the winter, and at the present time I have plots of these winter broad beans in four different portions of my garden, two sheltered and two fully exposed, and there is not a single plant missing from exposure. I usually plant the beans about the second week in October, as I found that those planted much earlier were sometimes cut down by the frost. Last year the beans did not ripen thoroughly, and a few failed to germinate. This was noticed in November,

Digitized by Google

and seed was planted in the vacant spots; the late-sown beans are now showing in the drills, which are about 1½ft. apart; the beans are dibbled in about a foot from each other, so that plenty of room is given for the plants to tiller.

Another sport or cross-bred is a white runner bean which I have grown for a quarter of a century. Its origin was a pod of four white beans found among scarlet runner beans. I planted these four beans away from the other runner beans and continued to do so for some years, as we found the white beans, when steamed, a very nice second vegetable. Some ten years ago a friend in New Zealand wrote that he had been growing some wonderful white runner beans which had been imported from Germany, and he posted a few beans to me. I sent him some of mine in return. The following spring I planted the New Zealand beans among those of my own growing.

As the growth of the beans for winter use was my chief object, I have selected each year for planting the pods containing the largest number of beans from the most vigorous plants. I have gradually increased the number of beans in each pod until, some three years since, I grew one containing eight beans, and my present stock is grown from these eight beans. In 1925 I had several pods containing seven beans, and though last year was not a good year for beans, I had several pods with six beans each.—SANDERS SPENCER, *Huntingdon*.

ASTILBES FOR THE BORDER.

SIR,—I was much interested in the article on "Astilbes" in your issue of March 5th, and I can certainly endorse your correspondent's remarks as to the excellent qualities of many of the varieties mentioned. The hybrids of A. Arendsii all make fine plants, and the illustration of the parent A. Arendsii from which many of these hybrids have been raised, may be of interest to many readers.—T., *Middlesex*.

THE SNOWFLAKES.

SIR,—Everyone has acquaintance with and loves the vernal snowflake (Leucojum vernum) and, when naturalised in thin woodland, or colonised on the rock garden, it is capable of creating a lovely garden picture. These little bulbs are pretty, too, when grouped in grass at the edge of the stream or lake, and as I write I can visualise from memory a beautiful effect so obtained. The congeners of this delightful spring-flowering bulb—not even the old-world summer snowflake, Leucojum æstivum—do not meet with the appreciation which they might well do; L. æstivum is a handsome plant producing spikes of drooping white flowers in May. About 1½ft. high, the leaves are of a fresh green colour, and it is a very fine border plant, or it may be very happily placed in thin woodland. The flowers are of considerable value for cutting. L. autumnale, sometimes referred to as Acis autumnale, is a real gem for the rock garden or for cultivation in pans or pots for the embellishment of the cool greenhouse, alpine house or frame; but a few inches in height, the dainty white and pink flowers are produced in autumn; it is quite hardy, and prefers a sandy, well drained soil and a half-shaded position. This little plant deserves to be far more widely grown than is at present the case.

L. vernum carpathicum or L. Wagneri, as it is sometimes called, is a glorified spring snowflake, and is larger in all its parts than is the well known typical plant. The large flowers are white, with each segment tipped green or yellow, the leaves a fresh bright green, and the whole plant some 8ins. or 9ins. high. This is a very fine bulb for freely naturalising in grass or for colonising on the large rock garden. The flowers are contemporary with those of L. vernum.

L. Hernandezi (syn. L. pulchellum) somewhat resembles L. æstivum, and produces in May scapes of pendent white flowers; 1½ft. high, it may be grown in the hardy flower border, where, like the summer snowflake, it will luxuriate in any ordinary good soil.

L. roseum, sometimes called Acis roseum, is a very beautiful little plant from Corsica, producing in autumn rose-coloured flowers; about 4ins. high, this little bulb is easily grown in a well drained sandy soil in the rock garden, or a few bulbs will furnish a lovely and interesting pan for the cold house. These snowflakes are increased by division, offsets being produced with fair freedom. They enjoy a half-shaded situation, and their cultural requirements do not present any great difficulty.—RALPH E. ARNOLD.

THE ELEGANT AND GRACEFUL ASTILBE ARENDSII, FROM WHICH SO MANY FINE HYBRIDS HAVE BEEN RAISED. *It is a fine plant for a shady moist border.*

OBTAINING QUALITY IN ROOT CROPS

SIR,—In your issue of February 19th, under the heading "Obtaining Quality in Root Crops," the following passage is quoted: "In the first place the ground must no. be of a heavy texture, or such roots as carrots and parsnips will grow forked . . ." Heavy soils, if they get into a lumpy state, may produce badly shaped roots; but if these soils are worked well and methods adopted to render them more friable, good specimens of root crops can be grown.

In my experience, the factor governing the forking of roots such as carrots and parsnips, is the digging in of copious supplies of farmyard manure prior to sowing, *i.e.*, in preparing the breaks for these crops.

I think it is better to give the ground a liberal supply of farmyard manure for the previous crops, the subsequent root crop receiving none other than artificials, *e.g.*, sulphate of potash before sowing and sulphate of ammonia during the growing period.

From the general tone of the article, one gathers that long, straight specimens are signs of good quality in root crops; they catch the judge's eye when such specimens are staged for exhibition. But quality is something entirely different and, I think, has more to do with flavour and nutritive value in this case. The nutritive value of a carrot lies in the outer red portions of the root, and the wider this is in comparison with the central yellow portion the higher the value. Potash appears to develop the outer red portion, hence its application to the ground prior to sowing root crops. Long, straight specimens are ideal and good to admire, but when grown on light soils, granted one gets shape, but the quality is lacking, the central core being often well developed.

Sandy soils as a rule lack in potash, whereas clays, generally speaking, are considered rich in this plant food, having originated in rocks containing it.—J. W. H., *Edinburgh*.

POTASH FOR TOMATOES.

SIR,—"Perthshire's" criticism (in the issue of THE GARDEN, February 12th, page 111) of my article on Potash for Tomatoes (January 22nd, page 56) is just that correct constructive criticism so helpful to the craft in general, and I thank him for it. Perhaps he understands, however, that by limiting my notes to potash, I left them open to such criticism as his; this may answer his main points. I agree that saltpetre is highly nitrogenous, but my point was that it is distinctly beneficial where potash had not been applied in good time; it is, therefore, used exactly as he describes and with an excess of soluble phosphates. The only other matter I may enlarge upon is that concerning wood ashes. I have sixteen houses under my eye; in only one of these are wood ashes used, so scarce is this commodity, and the application is approximately equal to the sulphate used elsewhere, as far as potash is concerned. The result is invariably better than elsewhere. I need not argue whether the potash or the other salts bring that about, but it explains my advice to use wood ashes for growing tomatoes.—LANARKSHIRE.

ANOTHER RAT TRAP.

SIR,—In your January 1st issue of THE GARDEN, page 4, under the heading "A Sure Rat Trap," a trap is described similar to one used on this side of the Atlantic, but I believe ours is better in two ways. We take a 45-gallon coal-oil cask, or similar vessel, place a brick on end in the bottom, and put in water to come nearly to the top of the brick; cover the end of the cask, as in your trap, with stiff springy paper firmly tied on. We then feed the rats for a few days until they have lost all fear of eating off the paper; then we cut the paper, as in your trap. The first rat then plumps into the water and mounts the brick. The next one that gets in starts a fight to get on the brick, and every rat within hearing rushes to the top of the cask and goes in, and a very large number may be caught at one time.—W. SCOTT, *Ontario, Canada*.

THE FRUIT AND KITCHEN GARDEN

An Early Crop of Celery.

A CROP of celery much in advance of the main crop may be secured in this way: During March sow a few seeds in a box of fine soil and place in a warm frame or greenhouse. Put a piece of glass over the box until the seedlings appear. The little plants should be given a light position near the glass and have a temperature from 55° to 60°. As soon as they can be handled transplant them 4ins. apart to shallow boxes filled with fine loamy soil. Keep the plants cooler and give plenty of air, although protection will be needed during cold nights. About the first week in May, or a little later, the plants should be 4ins. high, and they are then ready for putting out of doors. The early crop is best grown in single rows in trenches of rich soil 12ins. deep and 12ins. wide in an open part of the garden. Open these trenches some time before they are required for the celery, and the intervening ridges may be used for catch crops like French beans, lettuce, etc. The bottom of the trench should be well broken with a fork to the depth of a foot. With this early crop close planting is advisable, and the distance between the plants need not be more than 9ins. The soil should be pressed firmly round the roots and the plants watered in. Shade and protect with fir branches or sheets of paper for a few days. Give plenty of water in hot weather, or the celery will be likely to run up to flower. Keep the ground clear of weeds.

Earthing-up may be done in August, the first step being to remove all lateral shoots and leaves from the base of the plants and water well. Bring soil from the ridges, first breaking this well up in between the plants to the depth of 4ins. Add a few inches more soil a fortnight later and go on in this way from time to time, making sure, however, that the soil is never placed higher than the heart or growing centre of the plant.

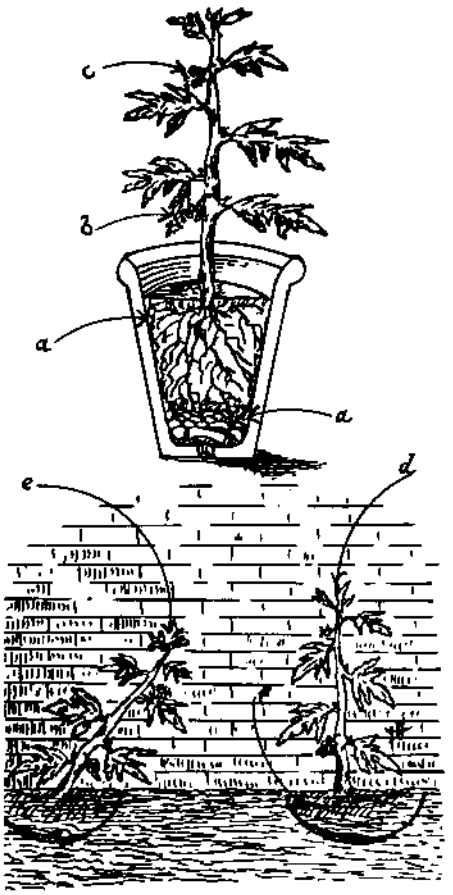
Lettuce: Cabbage and Cos.

How to Grow both Well.

UNDOUBTEDLY this is one of the most profitable of all garden crops, whether grown for market or home consumption. As the plants—under good cultivation—soon come to maturity, that is, to that stage when the hearts are perfect as far as solidity and crispness are concerned, several crops may be grown on the same plot of ground during the year. Even in the depth of winter lettuce plants may occupy the open border, as there are now first-class varieties for the purpose. The best time to begin the work of providing plants the whole year round is now. The cabbage varieties are best for raising under glass, as it is necessary to sow seeds in a greenhouse or a garden frame and to transplant the resultant seedlings. For very early use plants without hearts may be grown of the cos varieties by sowing the seeds in boxes about 5ins. deep and cutting the young plants, like mustard and cress, when they are about 4ins. high. This plan answers well in a frame or a greenhouse, especially the latter. For transplanting, seeds of cabbage varieties should be sown very thinly in boxes of rich, light soil, and the resultant seedlings transplanted in open borders early in the spring. These will follow the batches retained in boxes or in beds in cold frames and utilised from them. The first sowing of the cos varieties should be in an open border about the middle of April. If young plants of these or of the cabbage varieties are transplanted in a deep, rich, warm soil at the foot of a wall or between the trenches prepared for celery or leeks, they soon grow to a large size. It is the extra depth of soil on the ridges between the celery trenches that induces such luxuriant growth generally. Always raise the soil and roots with a garden fork when transplanting; do not forcibly pull up the plants, as so many roots are broken and bleeding occurs. For succession sow a few seeds only every six weeks, the last sowing for the winter and spring supplies being made at the end of August.—CHRISTCHURCH.

Tomatoes for Open-air Fruiting.

NEARLY everyone who possesses a garden or a frame and a small plot of ground likes to grow a few tomatoes for household use, and in many instances for exhibition at the late summer shows. Experienced



cultivators always try to obtain strong plants for planting out directly the danger from frost is past—about June 10th in the southern and a week later in the northern counties. Late-raised plants set their fruits late, of course, and if our summer is a cool one the fruits rarely ripen satisfactorily. Every seed should be sown separately about 1in. apart in a compost of fibrous loam two-thirds, old leaf-soil one-third and a free sprinkling of builders' mortar rubble. Water the soil before sowing the seeds, cover them lightly, but do not water the covering soil. Place a sheet of glass on the seed pan or box, also a sheet of paper, but set the seed vessel on a shelf in the greenhouse or in a frame in a warm position. Transplant the resultant seedlings when the second rough leaf appears, each separately, in small pots as shown in the sketch. Deep, narrow pots are the best if available. At first place the pots close together, but allow the plants more room as they grow. The object should be to secure sturdy, short-jointed plants. Do not allow the young plants to get too pot-bound before they are shifted to larger pots, and throughout May ventilate the frame freely, on fine days remove the glass lights altogether. The soil near walls, fences or even in the open borders should not be too rich. Do not dig it deeply; 9ins. is sufficient. If a hard pan of soil is left below that depth so much the better for the plants. Immediately around the stems firm the soil well while it is rather dry. When the roots in the pots begin to mat together, as shown at *a*, *a*, repot if the time for planting out is not come. Try to retain the lowest truss of fruits, *b*, and fertilise other trusses, *c*, as the flowers open. Where the walls are high enough plant and train upright as shown at *d*, on low walls train as shown at *e*. The portion of soil to prepare specially and make firm is shown at *f*.—GEO. GARNER.

Mid-season and Late Potatoes for Exhibition.

ALL exhibitors wish to be successful, but they will not meet with success if they do not take extra pains with the work connected with the cultivation of the various crops. Potatoes claim first attention by the majority of growers, and at local shows more dishes of them are staged than of any other kind if we include the whole of the country. Few early varieties are exhibited, but chiefly midseason and late sorts. If the soil is dry enough to work without any of it sticking to the tools, it cannot be broken up too finely if of a heavy, retentive character. Something can be done to it during the summer months, but not immediately around the young, growing tubers. The preparation of the soil should be complete practically before any tubers are planted. Fine tubers can be grown in pure leaf-soil alone. I do not advocate this generally, but if any readers possess heaps of old leaf-soil I advise them to level the mould, add some old chrysanthemum or potting soil sifted to remove lumps, and try a few special tubers for exhibition purposes. In such a rooting medium the "sets" should be planted about 7ins. deep and a spadeful of the same kind of mould placed right in the centre of the haulm instead of earthing up in the usual way. Tubers so grown are generally large, of grand shape and exceptionally clean of skin. In every case a careful selection of tubers bearing sturdy sprouts should be the rule. Undersized and prematurely sprouted tubers are not suitable. In the common, open border it is not necessary to have the rows extra wide apart. Follow practically the usual method of planting, but allow the "sets" an extra 3ins. in the rows. It is a common mistake to place the tubers too closely. If there is a heap of burned garden rubbish in the garden, scatter some freely in the drills, on the tubers, before the latter are covered with soil. Do not on any account use fresh organic manures. Mos growers have their favourites, but I think all will like Arran Comrade and The Bishop. The first named is round, the last kindey. King Edward VII is a beautiful potato in most soils, but as earthworms are so partial to it it is advisable to sprinkle dry lime on the sides of the drills, not on the tubers, before covering the latter. On the surface use wood ashes freely, sprinkled on in a dry state when the haulm is growing and covering the soil. Lift the haulm and scatter the ashes underneath.—HANTS.

The Loganberry.

THIS free-fruiting plant may be planted with great success now. It is a strong-growing subject, its branches cover considerable space—even when planted late—in

Digitized by Google

one season. Ample room is required if proper treatment is to follow. Owing to plants being too close together, the branches become entangled, difficult to disentangle and, consequently, they are often left in this condition and become a mass of young and old shoots mixed together. Twelve feet apart is the nearest to plant if the branches are to be trained out to right and to left. These plants are suitable for training on division fences in certain cases. Cleanliness of soil is essential; plants choked with weeds do not thrive. They thrive where leaf-soil is added.—HANTS.

Soils Not Dug Last Autumn: Their Present Treatment.

I HAVE, recently, been busy digging part of my own garden which was not dug last autumn. Late in the summer and almost throughout the autumn, the soil, in many districts, was much too hard to allow of any effective digging or trenching. Of course, conditions were not similar all over the country; there were, fortunately, many exceptions. I daresay many readers of THE GARDEN whose soil is rather heavy loam have been similarly placed to myself. The soil I have been digging was in a fit condition, and unless this is the case, the digging should be deferred until it is. No opportunity to dig deeply should be missed now if the soil is kindly, not sticky and adhering to tools and boots badly. All soils so treated now will be in really good condition for the seeds and young plants from the latter part of March onwards. When engaged in late digging, the inexperienced person should, at this time, break up all lumps finely except the top ones. The ground is to remain undisturbed for a short time, and at the end of it all those surface lumps will fall to pieces like powder when knocked about by the tools, and throughout the summer months it will remain in a kindly condition to work.

Mostly, it is our clayey soils that cause the greatest trouble when seed-sowing time comes. I have in my mind at the moment a gardener who recently told me he could not grow carrots in his garden as the soil was too stiff. I know this particular garden very well. It is typical of scores of others in the same district, and the owner grows fine vegetables, excellent roses and stately herbaceous plants; but the carrots are not forthcoming. They can be grown, however, very satisfactorily in that and similar soils. He prepares the ground for this crop much the same as the bed for cabbages. This will not do, however. A special plot should be deeply dug and all lumps broken as small as possible at the time; then rotted leaf-soil, old potting soil and similar material should be collected and thoroughly mixed. Add a small quantity of wood ashes and heap the whole, keeping it dry—from excessive rain-water; in the meantime, when the border loam is getting dry, towards the end of March, put down the garden line and, with the spade inserted near to its full depth, pull towards your direction as you stand, holding the handle, thus leaving a narrow opening the depth of the spade. Fill up with the prepared compost, which has been passed through a ¼in. mesh sieve, and so on until the whole length of line is similarly treated. Sow the seeds immediately on the filled-in trench and cover them with fine soil. Very fine carrots may be grown in this way, and the little extra trouble will be justified.

Potatoes cannot be grown very satisfactorily in a lumpy soil, and so the correct thing to do now, when digging the ground, is to render the soil as fine as possible rather than attempt to do it when sun-dried. With naturally light and sandy soil there never is any real trouble regarding its preparation.—CHRISTCHURCH.

IN THE GREENHOUSE

A Handsome Conservatory Plant.

THE old greenhouse plant known as African hemp (Sparmannia africana) is a very good subject for clothing the wall of a conservatory. Most people know the plant, with its softly hairy leaves of an intense green and its large clusters of white flowers with their central group of golden tipped stamens. In an ordinary greenhouse the sparmannia often develops on somewhat ungainly lines, and it is at its best when, with some support, it is allowed to spread up a wall. Within the writer's experience the sparmannia will stand quite low temperatures under glass, for, even if some of the foliage is damaged, vigorous growth is soon restarted. If properly treated, the African hemp will remain in flower for a very long time, and usually the blossoms, which begin to appear in the early spring, continue a display until late in the fall. To secure the longest flowering period the sparmannia should be in the sunniest position that can be obtained, and, within limits, the poorer the soil the better. If the plant is luxuriating in a very rich soil it becomes a fine specimen from a foliage point of view, but flower production is inferior. Where convenient the sparmannia may be planted directly into the soil at the base of the wall; but, in many cases, a pot will have to be employed. There is no object in having this very large unless a considerable area of wall has to be covered. If the plant should ever become too extensive, it may be freely cut back, and a somewhat severe pruning will often result in an increased flower production.—A. B.

Early Peaches and Nectarines.

SOMETIMES the amateur cultivator experiences much trouble through the flower-buds dropping off wholesale at the present time. There are several reasons for the buds dropping. The first cause is, probably, lack of water at the roots early last autumn as well as through the wintertime. The second cause may be through erratic ventilation during the winter; sometimes the ventilators are closed for several days while the weather is rather mild and the sap is excited a little. Then the ventilators and doors are left wide open, perhaps in cold weather. Another cause, lack of water at the roots recently, just before the house is closed, and too much fire-heat. Some varieties are more liable than others to drop their buds. The forcing should begin by applying a little artificial heat only. When the first flowers open cease syringing, generally, and admit a little top air, but none at the front. Sharply tap the branches several times a day and also fertilise the flowers by hand, especially those well placed, using a camel-hair brush or a rabbit's tail. Watch for black aphides and fumigate directly the bulk of the fruit is set.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

How to Cultivate Large Shallots for Exhibition.

To grow fine large shallots requires good cultivation and well drained soil. Select a plot of ground not too heavy, as shallots thrive best in light soil. Dig two spits deep, or bastard trench, dig in a good layer of rotten mellow farmyard manure, and give a dressing of soot, then let it lay rough until a few days before planting. Draw a ridge with a hoe 6ins. high, 9ins. wide, working in at the same time a dressing of bone meal, then level ridge down with a rake. Plant the shallots in single rows along the centre of ridge at 10ins. apart. The ridges should be 18ins. apart. When plants are 6ins. high, give a dressing of soot on a rainy day. I have grown shallots on ridges and on the level side by side. Shallots on ridges are far the best. They get more sun, there is more room for the bulbs to grow and they ripen much better. When bulbs begin to swell give a soaking of liquid manure; this will increase their size. Sutton's Giant is the best in cultivation.—B. R.

A Method that will Destroy Roots and Stumps of Large Forest Trees.

To destroy nuge stumps and roots of trees. Get an inch auger bit, bore several holes as deep as you can bore, fill up with weed killer, then plug hole with a cork. Remove cork every month to refill with weed killer; eighteen months with this treatment will kill huge stumps and roots of ash, elm, walnut and all stumps. The weed killer soaks into the heart of the stumps, blacks and rots everything that comes in its way; it decays and simply rots away. This remedy was applied on a large Hertfordshire estate with great success.—B.

Protection Against Slugs.

So many people burn "Perfection" stoves now, that those among them who are gardeners may be glad to know that the perforated zinc collars that surround the wicks may be put to a very practical use in the garden, when the wicks are done for. They should first be put in the fire to burn away every scrap of wick and then the collars are most useful to protect small plants and bulbs from the ravages of slugs. They should be pressed well into the soil round the plant with the sharper rim uppermost. I have always found them most effective in the rock garden.—M. H.

Garden Refuse.

Economy is necessary in all gardens to-day, and one of the items that lends itself to such is the disposal of garden refuse. A garden fire will destroy all tree prunings and yield up with the ashes an appreciable amount of potash. Throughout the year all weeds, lawn mowings, discarded bedding plants and any other rubbish should be heaped together. In the autumn all available leaves should be added, and also one barrow of good loam to five of rubbish. To complete the heap apply sulphate of ammonia at the rate of 14lb. to each cartload of rubbish, and then turn thoroughly, moulding the surface so that the water will run off. In one year's time the heap will be available as a substitute for farmyard manure, and the percentage of nitrogen available will be higher.—W. M. C.

Primula Seed and Germination.

In many instances primula seed fails to germinate and often causes trouble when batches of plants are required. Especially is this so with Primula obconica grandiflora (pink, blue and blue shades, which are very useful for table decoration at this time of the year). P. malacoides, also hardy primulas Beesiana, Bulleyana, denticulata, Lissadell hybrids and sikkimensis. Seed of all the above varieties will germinate more freely if sown when gathered from the seed pods instead of getting hard and dry. Seed may be sown in pans or boxes half drained with small crocks and filled with a mixture containing leaf-mould, old loam, broken crocks or old mortar rubble passed through a ¼in. sieve, and silver sand. Do not cover seed with soil, keep damp and cover with a piece of glass till germination takes place.—W. R. P.

A Hint on Growing Good Carrots.

Choose the lightest piece of land in the garden. As soon as the land is dry enough, cover over with burnt ash and soot. Dig full depth of spade, leave to dry, then fork over, adding a little more soot. When the time comes for sowing, fork over again, rake level, draw the drills 15ins. apart, into each drill sow a good sprinkling of common mustard, then the carrot seed. As soon as the seedlings are 1in. high soot the bed every ten days. No other manure is required.—L. R.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Box Trees in Pots.

I shall be glad if you will kindly give me advice concerning two pyramid box which I purchased three months ago; these were planted in large pots, with gravel and clay soil and at the time of planting they were trimmed to keep their shape. and now I notice the leaves at the base of the trees are going brown. Can you tell me how to prevent this going any further.—E. O'C., Sanderstead.

November or early December is not a good time to move box. September and late April or early in May are the best seasons for transplanting. The leaves turning brown suggests that the roots were damaged in moving, and are unable to supply sufficient nourishment. We suggest that you move the plants to a greenhouse, if possible, which would encourage the immediate production of new roots.

Some Low-Growing Rock Plants.

I have an elevated lawn with rockery round. I want some low, hardy perennial mosses or such like that will creep over the stones. I see some very close green carpet plants about, but do not know their names; shall be glad of your aid.—G. J., Newport, Mon.

We should suggest that for the rockery running round your lawn you plant some of the mossy saxifrages, such as Saxifraga hypnoides, S. Maweana, S. decipiens and S. Wallacei. We should also suggest Raoulia australis or Nertera depressa (if in a warm and sheltered position), or Gentiana sino-ornata. For splashes of colour aubrietias, such as the variety Dr. Mules; Iberis sempervirens; Alyssum saxatile and arabis. These we think you will find suitable for your purpose.

The present is an excellent time to plant Phlox, Delphiniums, Michaelmas Daisies, Pyrethrums and many other plants which do not care to be disturbed in the depth of winter. If any renovation or rearrangement of herbaceous borders is required, it should be put in hand at once.

Our Catalogue of Hardy Border and Rock Plants is a profusely illustrated guide of 52 pages, and may suggest many interesting and new plants for your borders. It will be sent post free.

The whole of our stock of Hardy Plants is transplanted every year and grown with the greatest care under very hardy conditions. They consequently invariably do well and quickly grow into strong flowering clumps.

THE GARDEN

VOL. XCI.—No. 2885. MARCH 19, 1927. PRICE TWOPENCE.

THE FLOWER FOR EVERY GARDEN

IN our desire to stimulate further interest in the cultivation of the gladiolus among all amateur gardeners, we again devote a special issue to these popular garden flowers at the height of their planting season. Last year, we published our first gladioli number and it proved so popular that we have repeated the experiment and hope in future, to make it an annual event. Certainly there is no flower more worthy of having an issue devoted to it than the fashionable gladiolus. It is one of our modern garden flowers which has come to stay. The popularity of all the various kinds is on the increase and, while it is no longer a flower seen only in a comparatively few gardens, yet there are still many gardens where it should take its place along with the rose, sweet pea, tulip and daffodil as an integral part of the garden display.

Gladioli are pre-eminently flowers for the amateur. Their qualities are those which the amateur desires to see in every plant, namely: (1) Ease of culture. (2) Grace and beauty of habit, which renders them suitable for planting in either beds or borders by itself or in association with other subjects. (3) Wide range of alternative colourings; and (4) Excellence as a cut flower for interior decoration, not only on account of their beauty of form, but also for their lasting qualities. Few of our garden flowers combine these four qualities to such a marked degree as the gladiolus and for that very reason we would urge everyone who has a garden to plant a few corms this season as a trial. Next year, we feel sure, the space devoted to its culture will be increased. No matter where the garden is situated, the gladiolus will succeed. It does equally well in the town as in the suburban and country garden. It is not fastidious as regards soil, and unless that be of a very inferior and poor quality, then no precautions need be taken to improve it.

They flourish well in soils of a medium to heavy nature where peat is present and they succeed equally well in light, sandy soils. On the whole they are averse to limy conditions and where there is much lime in the soil, or if this is of a cold, tenacious and clayey nature, then it is advisable to prepare a special bed of sand, grit and good loam, with a little well decayed cow manure. At planting time, give each corm a small amount of sharp sand to rest on, and plant about 3ins. to 4ins. deep and about 5ins. to 6ins. apart. Deep planting to a certain extent does away with the necessity for staking, but it is not always advisable, and when the beds are exposed to strong winds, then insert the stakes at planting time, to prevent the plants, when they have reached flowering size, from being blown over and broken. The actual date of planting gives rise to some controversy. Every year seems to bring it earlier and earlier, but experience shows that the last fortnight in March may be taken as early enough to begin planting. When well started planting can be continued until the end of April at intervals of ten days or so, so as to provide a succession of flower later on in the year. The planting of gladioli, as with other subjects, is largely governed by the state of the weather and also by the condition of the corms when purchased. It is best to purchase corms which are dormant, that is, not showing a green point. Immediately pointing takes place, then planting must be done at once.

When planting, select positions in the garden where the flowers will be seen at their best. The gladiolus, like many another flower, must have a background to show itself to advantage, preferably one of dwarf evergreen shrubs, or against an old wall of sombre colouring. Amateurs, with an observant eye, will see many examples of this type of planting in many of our public parks. One which we recall was the border of gladioli in Greenwich Park last year. The border, with its attractive and varied shades looked well against the background of evergreen shrubs. This is an arrangement which could quite well be followed on a smaller scale by many amateurs and their gardens would gain much in beauty and appearance.

This Week's Work

Strike cuttings of border chrysanthemums now in frames.

Finish planting perennials and shrubs as soon as the soil is in suitable condition.

Repot fuchsias, palms, aralias and aspidistras.

Sow hardy annuals in the open.

Plant shallots, artichokes and potato onions.

Protect wall fruit from birds and frost.

Prepare asparagus beds and sow onions, carrots, parsnips and leeks.

Start dahlia tubers into growth by placing them in boxes in the greenhouse.

Prepare new lawns and sow grass seed when the surface soil is dry.

Plant anemones in prepared borders.

Their inclusion in the herbaceous border is largely a matter of personal taste. In bold, large clumps of perhaps a dozen plants or more they look well if planted with regard to the habit and colourings of the subjects close by. Avoid incongruity at all costs by the planting of two or three corms here and there along the border. Such a method will not add beauty to the border or grace to the gladiolus. They look well in beds on a lawn and a good method to follow is to associate the large-flowered and the primulinus types together, the former as the tall tier and the latter as the groundwork. If the colourings are chosen so that they do not clash, then the effect is most attractive. Apart from their planting in the actual flower garden, a small reserve bed or border should be planted up to supply cut flowers for the house in the same way as the sweet pea.

We have not reached the culminating point in the popularity of this elegant garden flower. Interesting although its history is, its future should be still more so if our leading growers follow out the lines they are already on. There are about a hundred and fifty species of gladioli, the majority of which come from South Africa and in recent years, many of these have been and are being introduced into this country for the purpose of further hybridisation work. What the result will be it is difficult to guess, but it is certain that we can look forward to a gladiolus flower which will be a marked improvement on what we have at present. The introduction of the primulinus in the nineties of last century has contributed greatly towards the increased popularity of the flower by producing our modern varieties, with slender arching stems and hooded flowers and of the most delicate colourings, the results of crossing this species with the large-flowered Lemoinei and Childsii races, which, in turn, originated from the hybrid race referred to as G. gandavensis.

There is still open a wide field for further experiment. Numbers of sweetly scented species, such as G. tristis, the South African Avondblom, are in existence and their introduction and use in hybridisation work in this country seems especially desirable, since up to the present our modern hybrids are lacking in fragrance. Their colourings can be improved, and in this connection much may be done by attempting crosses with some of the delicately blue Babianas. Hi-generic crosses should prove successful and also fertile in such an instance. These are only suggestions flung out in the hope that a few of our growers may follow on these lines, because we feel sure there is a great future for the gladiolus if these few further improvements can be registered. G. C. T.

GLADIOLI FOR INDOOR DECORATION

There is no more useful or beautiful flower for vase decoration than the gladiolus. Here are a few hints on how to arrange the different types to best advantage.

THOUGH gladioli may be very beautiful when used simply and solely as bedding subjects, in my opinion they are only seen at their best when cut and tastefully arranged in the home. Both the large-flowering varieties and the primulinus hybrids possess qualities which render them invaluable as cut flowers.

Now is the time to purchase gladiolus corms and in choosing a collection of varieties to be used for cut flowers, one should not only select suitable colours for the purpose, but take into account their respective times of flowering. Different varieties come into bloom at different periods if planted at the same time, some as early as July, others at the end of October and of course, at all times in between. A little forethought may avoid disappointment. If one wishes to plant all one's gladioli about mid-March, it is wise to select varieties strictly according to their time of blooming. Most catalogues give this necessary information, as a rule, classifying them roughly into three sections, early, mid-season and late. The time of planting does, to a certain extent, determine the time of flowering. It is a simple matter, by a judicious choice of varieties, to obtain a comparatively lengthy flowering season and to regulate to some extent the time of blooming of individual varieties.

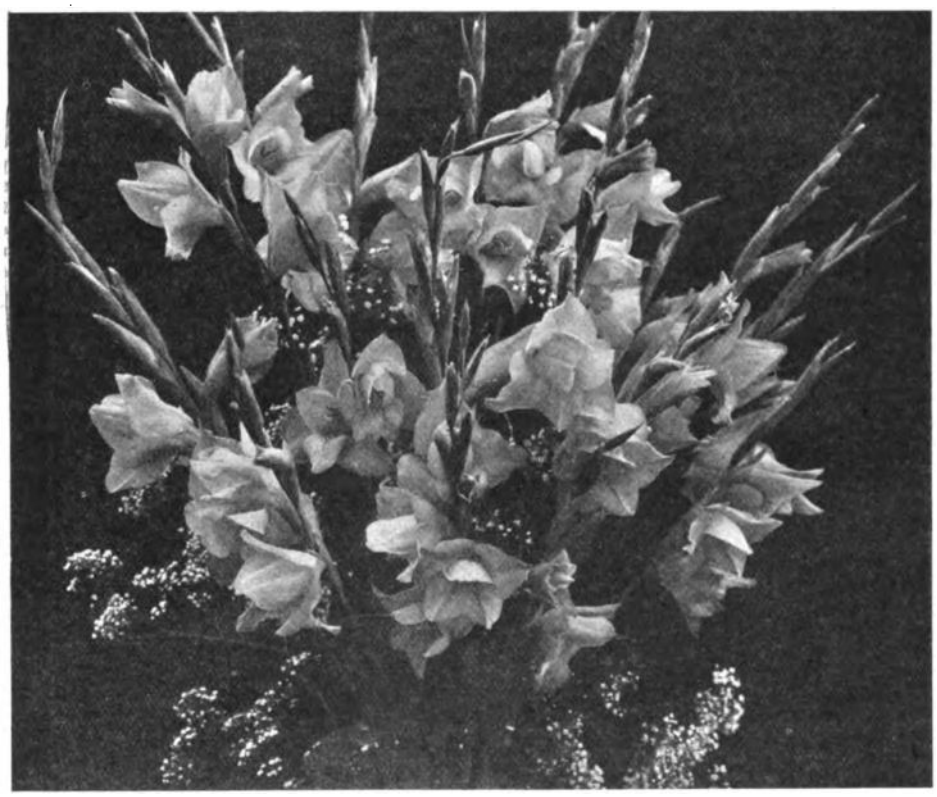
A sunny spot in the kitchen garden is ideal and if there is some protection from the prevailing winds, so much the better. staking each individual flower spike will be unnecessary, if strands of string, fastened to stakes, are passed horizontally on each side of the rows. A word of advice to the grower to *plant sufficient corms*. It should be remembered that gladioli are not quite like sweet peas or roses, a single corm of the large-flowering variety usually produces but one flower spike in the season; primulinus hybrids will give one, often two and sometimes three.

In discussing the effective arrangement of gladioli indoors, the two sections, large-flowering and primulinus hybrids must be dealt with separately, for in many ways they are quite different and need different treatment. There is one point, however, common to both, to which I must direct attention, and that is the actual operation of cutting the spikes. The leaves are the "lungs" of the plant and if these, or most of them, are cut off with the flower spike, the proper formation of the new corm is impossible for the following year. In order to cut the flower spike with a minimum of injury to the leaves, quite a good plan is to insert a sharp penknife in the stem, give the spike a gentle jerk each way, till it snaps, then it can be readily be drawn out of its sheath of base leaves. In both sections the spikes should be cut when the bottom bloom is fully open, then every flower bud will open in water indoors in succession. As the bottom blooms die, they should be broken off day by day and a small piece at the base of each stem cut off. This procedure will give one a fresh bunch of flowers from the same spikes for at least a week, often nearer a fortnight, an advantage which gladioli possess over most other flowers and a point which flower lovers will readily appreciate.

The large-flowering type are, as a type, very stately, majestic and perhaps rather massive in appearance and are undoubtedly more difficult to arrange effectively than the smaller-flowered primulinus hybrids. It is all too easy to obtain a heavy-looking and rather formal appearance, indeed, the spikes themselves are weighty and any attempt to place them in a light vase, bowl or basket will, as a rule, result in the whole toppling over. Receptacles must be heavy without appearing to be heavy or ungainly. Rather tall, thin vases containing several spikes are very attractive on the mantelpiece, while tall and slightly larger vases may be arranged effectively on a sideboard or small occasional table. Fairly large baskets or large, deep bowls admirably fill a fireplace or corner of the hall, or even the centre of a large table. Some means of support for the spikes will render the work of arrangement much easier and more satisfactory. Usually, baskets or large bowls intended for floral use are fitted with wire mesh supports in two "layers," fastened on a wire framework horizontally, the top "layer" almost on a level with the rim of the basket, the bottom one, 2ins. to 4ins. lower, according to the size. These or similar supports allow one to place each spike exactly where one wishes and at any angle, without fear of its twisting round in that tantalising way well known to all who have tried to arrange gladioli. Of course, in smaller vases where only two or three spikes are used, a wad or two of paper or cotton wool will keep them in the desired positions. I find that there is a strong temptation to overcrowd the spikes in baskets or bowls, and to arrange them too formally. Place some of the spikes at an angle, not all of them bolt upright like slats on a fence, and break up formality by using light foliages, such as Asparagus plumosus nanus or A. Sprengeri. In my opinion very few foliages may successfully be arranged with gladioli; those mentioned are my favourites, but I have used sprays of copper beech and the copper-foliaged prunus to enhance the effect of salmon, light orange, yellow, cream, white and other colours, with which they blend. Just a few co ours, usually the dark shades, will allow the inclusion of golden privet. Gypsophila is often effective, but its use should not be overdone.

Unlike many flowers, it is difficult to mix different varieties of various colours and obtain as a result an obvious "clashing" of tones. On the other hand, a little care taken in the choice of shades for a "mixed" vase or bowl will give one the most attractive effects. On the whole I prefer to use one variety to each receptacle, but realise this may be somewhat difficult where comparatively few corms are grown. Space will not allow suggestions for colour blendings and after all this is largely a question of personal taste. Naturally, one chooses light shades to place against a dark background, bright rich colours for a dull position and take into account the prevailing colour (or colours) of permanent furnishings and decorations.

Beautiful though the large-flowering type may be for home decoration, they are easily surpassed by the primulinus hybrids. The latter possess thin, wiry stems, with the individual florets spaced comparatively widely apart. Their smaller blossoms have the top petals hooded in a demure and charming manner, while their colours embrace the most wonderful art shades imaginable, the soft salmons, rich oranges and delicate creamy salmon-pinks being particularly attractive. They lend themselves to easy arrangement as do sweet peas. Dainty and graceful, they may be arranged in quite small vases and bowls. Much that I have already written concerning the arrangement of the large-flowering varieties is equally true when applied to "prims," but I would again emphasise the advice to avoid overcrowding. C. U.



A WELL ARRANGED VASE OF A MODERN PRIMULINUS VARIETY. SPRAYS OF GYPSOPHILA ARE USED TO LIGHTEN THE EFFECT.

NOTES ON THE FLOWER GARDEN

The Californian Poppy.

THOSE gardeners who secure a plant of the Californian poppy (Romneya Coulteri) for the first time always wonder why they have never grown such a splendid subject before. The species is a glorious shrub with flowers 6ins. across, pure white, save for the mass of golden stamens in the centre. It is true that the Romneya is not thoroughly hardy in the colder parts of this country, but it is worthy of a little special treatment. In all localities it is best to give the plant a sunny position sheltered from the north and east as much as possible. Romneya is not herbaceous, and the deeply cut glaucous foliage is retained throughout the winter. The flowers are borne chiefly on the points of the new shoots and on laterals nearest the points, but more sparingly on the lower laterals. The shrub likes a rich light soil, and it is not much of a success on cold clay unless the situation has been well prepared in advance. A great point which recommends romneya is the fact that it is of rapid growth. Year old plants have grown vigorously and flowered abundantly from the end of June to the beginning of October where the position was favourable. It is not at all an uncommon thing for the shrub to send up shoots 7ft. in length during the growing season, and all of these produce large numbers of flowers. Even those who live in rather bleak districts should not despair of growing Romneya. It has been proved that the root-stock of the shrub has a large amount of vitality. During severe weather it is an excellent plan to cover the ground with dry litter, and then, should the top growth be cut down by frost, new shoots will appear in the spring, so that by the summer the bush will be as good as ever. Another good species, rather an improvement on Coulteri, is R. trichocalyx, a novelty offered by Messrs. Barr's this year. Like its relative, it carries large snow white flowers.

THE GLORIOUS BLOSSOMS OF THE CALIFORNIAN POPPY.
An excellent shrub for a sunny position in the small garden.

The Spanish Heath.

THE Spanish heath, Erica australis, is one of the most distinct of the species usually grown outdoors in Great Britain. It must be included among what are commonly known as the "Tree Heaths," though it seldom exceeds 4ft., or occasionally 5ft., in height. It is in flower from March until May, and its large cylindrical blossoms are of a brownish red colouring, quite distinct from that of other species. The growth of the plant is loose and whippy, but by no means unattractive, and a western aspect in thin woodland or with other shelter seems to suit it as well as complete exposure, while safeguarding it to some extent from killing wind-frosts. This species succumbs to a hard winter in many places, but it is hardier than most forms of cistus and other plants we habitually grow outdoors, and its beauty is such that its culture should by no means be neglected. Stock is easily increased from cuttings of half-ripened wood rooted under glass, or it may be raised from seeds.—R. V.

A Dainty Bulb for a Warm Border.

THE quaint and undeniably pretty bulbs of Cypellas may be planted during March, choosing for them a sunny position and a well drained sandy loam; if not lifted annually and they are better so treated, the bulbs must receive some protection during the winter, a frame or handlight proving very serviceable.

The two or three species are very easily grown and are sure to command attention and admiration; the most familiar is C. Herberti from Buenos Ayres. The flowers are chrome yellow, produced on a scape about 1ft. or rather more in height.

C. plumbea, a Mexican species, is a remarkable plant with coral coloured flowers, slightly tinged yellow at the centres; it is synonymous with Ferraria coelestina and Phalocallis plumbea. C. platensis from La Plata has very beautiful sky-blue flowers and is a larger plant than its congeners; while the somewhat rare Peruvian C. peruviana is yellow and brownish red, a desirable plant.

Not unlike tigridias and responding to similar treatment, these cypellas have grass-like leaves and are well adapted for growing in a warm border or rock garden. Not at all fastidious, they are certainly worthy of more extended cultivation.—R. E. A.

Giant Dahlia-Flowered Zinnias.

Chiefly from Scottish Tests.

THE giant dahlia-flowered varieties are a great advance on those formerly grown. Like all the zinnias, these new varieties must have an open, warm border reserved for them; in addition to that, the soil requires to be light and well opened up by deep digging, ameliorated by the addition of leaf-mould, and enriched fairly heavily by the addition of good manure. In the north it is best to sow about the middle of March, but friends farther south can have equally good results from sowings made at the end of this month; the seedlings can, thereafter, receive individual pot treatment or they may be grown in boxes. Treated like the usual run of less half hardy plants, hardened off in May and planted out during the first fortnight in June, they will give no trouble and need no extra care. I might add, here, that zinnias cannot withstand wind and their outside site must not be exposed in that respect. The merit of these new zinnias lies in their size; plants will reach to a height of 3½ft. to 4ft. and the flowers are correspondingly large—last year they were from 4ins. to 5ins. in diameter, in the main. The gorgeous tints are also an outstanding attraction; flowers of the sun, they have all the flaring, striking colours one expects in tropical plants and this should prove a strong point in their favour, something we cannot get easily in other flowers. Our first varieties were obtained direct from U.S.A. and included Meteor, Exquisite, Oriole, Dream, Buttercup and the white Polar Bear. These are now easily obtainable from Messrs. Dobbies of Edinburgh, and there may be added the other fine varieties. Crimson Monarch, Scarlet Flame and Golden Land.—LANARKSHIRE.

Sea Lavender.

STATICE LATIFOLIA is the botanical name of the great sea lavender. It is generally regarded as the finest of the hardy members of this family and no garden should be without a few plants.

The large, shining leaves are more or less evergreen and in August it sends up stout, branching, flowering stems which bear a profusion of tiny lavender coloured flowers. These remain in good condition for a considerable period, but do not persist after they are cut and dried as do the flowers of many sea lavenders. The white calyces remain attached to the flowering stems, however, which, when dried are useful for mixing in with other "everlasting" flowers.

Although in its native state this plant is found growing in sandy soils near the sea, it succeeds quite well in any ordinary garden soil and even makes luxuriant growth on clay soil if well drained. An open, sunny position is essential for success.

S. latifolia makes a strong tap root and does not transplant well; it should therefore be planted where it can be allowed to remain undisturbed. Propagation may be effected by means of seed, but this is rather slow, and if the plant is lifted and divided the loss of the whole plant is risked. The best method is to take off the side shoots with a "heel" of the root attached. Insert these in small pots filled with a sandy compost and place in a shady situation in a close frame or cool house until they become established. They may then be potted on until they are large enough to plant out.—T. H. E.

GLADIOLI FOR NORTHERN GARDENS

Specially written for amateurs in the north, giving varieties suitable for growing in Scotland.

THERE was a time, and that not so long ago, when the gladioli was considered by most Scottish amateurs to be too stiff as a floral subject for the decoration of the garden. That effect was accentuated in some instances by the method of planting, which consisted of planting the corms singly and at varied distances in the mixed flower border. Grouping was the exception rather than the rule, and a bed exclusively devoted to the culture of gladioli was the work of a comparatively small body of enthusiasts who specialised in that particular flower. The whirligig of time has brought about a remarkable change. The gladioli has advanced in favour until it has reached a degree of popularity hitherto unparalleled in its history. No garden is now considered complete without up-to-date examples, massed groupings are now a feature in the border, beds containing choice collections are quite common, and last year the displays of hybrid gladioli and primulinus were outstanding both in the trade and competitive sections of town and country exhibitions.

Of the various influences which have contributed to the progress of the gladioli, three may be mentioned. First of all I would place the hybridist, who is responsible for the creation of new introductions which are incomparable for their grace of form size of blossom and beauty of colour. With that work the name of George Mair, Prestwick, is prominently associated. For over forty years he has been actively engaged in the raising of an improved race, and the high quality of his pedigree seedlings is famed all over the world.

The advent of the primulinus with its ever-increasing and charming group of hybrids has also contributed to the popularity of the gladioli among amateurs, and in the third place the recognition of improved methods of culture has had the effect of raising the quality of the flowers to such a high standard of excellence that new recruits have been attracted to the ranks of admirers whose chief aim is the decoration of the garden.

To grow gladioli successfully a good, deeply dug soil is essential. In late autumn the top soil should be removed and a liberal dressing of decayed manure incorporated with the subsoil. If the ground is stiff, leaf-soil and sand may be added. In early spring—just about this season—give the surface a dressing of wood-ashes and bone flour at the rate of 3 oz. to 4 oz. per square yard and lightly fork it in. Here in the north country it is risky to plant the corms in the open ground before the beginning of April, and even then it is advisable to surround the corm with sand to prevent it decaying. The arrangement of the gladioli is a matter of personal taste. When grown in beds single rows of one variety make a pleasing display, but if grown at intervals in a mixed border they look best when planted in groups of not fewer than three.

Gladioli are easily grown from seed sown in pans or boxes in spring, but the general practice among amateurs is to purchase new varieties and preserve them over winter by lifting the corms in autumn and storing them in shallow boxes filled with dry sand.

I believe in staking gladioli at the time of planting, as there is less chance of injury to the corm. It also indicates its position before growth appears above ground.

Where colour varieties are numerous it is not an easy matter to make a selection. Experienced growers have their own points of view and need no guidance, but beginners may rely on the following inexpensive varieties as the genesis of a representative collection :

Large flowered varieties.

Odin, salmon with deep red blotch ; Red Emperor, glowing orange scarlet ; L'Immaculee, free-flowering white ; Empress of India, deep velvety maroon ; Yellow Hammer, deep yellow self ; Prince of Wales, one of the finest of the salmon pink shades.

Primulinus varieties.

Orange Brilliant, orange, shaded scarlet and yellow ; Maiden's Blush, pink ; Daphne, vermilion ; Salmonea, salmon flushed orange ; Niobe, orange self ; Souvenir, yellow self.

HOW TO GROW FINE GLADIOLI

EVERYONE interested in gardening must have noticed that, during the last quinquennium, the gladiolus has drawn to itself an ever increasing popularity ; but during the last two or three seasons an entirely new and much more vigorous appreciation has developed, till now it basks in the sunlight of widespread acclaim. Never before, not even at the advent of the gandavensis, Childsii, Lemoinei or Kelway hybrids, has the cult of the gladiolus received such stimuli as are now pushing it to the forefront of the so-called " florist's flowers."

Many thousands of gardening folks will be planting gladioli during the next few weeks, and a few practical remarks regarding culture will be timely. Some sluggish and inert pursuers after garden beauty find refuge from exertion in such stock phrases as, " Yes, very nice, but they are too much trouble to grow and look after." Now, of all the Weary Willies in our land, there can hardly be one so perfectly weary as to shirk the amount of work needed to grow this flower. Corms and bulbs are, in a sense, clockwork plants, with all the impetus of growth and flowering wound up in their portable root stocks, and the zero minimum of labour is just to put these into the ground and pull them out when they again become dormant in autumn or early winter. Spikes of bloom would not be denied even this careless treatment, but it would not satisfy the cultivator. Even so, there is no need for much exertion in the production of the best results, and therein lies one of the secrets of popularity.

Soil.

It is a moot point which soil is the best for the gladiolus, but my experience is that it is satisfied equally, or apparently so, so far as concerns corm production, in practically pure sand and in stiff clay. Every sort of soil between these extremes appears to be equally favourable, provided that poor land is suitably enriched and low-lying, heavy ground is properly drained. Autumn is the correct time to prepare the beds if manure has to be incorporated, for the latter must be well decayed before it is acceptable to the roots of the gladiolus. Land which is in reasonably good heart is all the better without animal manures ; if it is simply turned up rough for the winter, forked down into tilth as soon as the weather permits in February or early March, and given a good sprinkling of bone-meal before the final cultivation prior to planting, enough will have been done in the way of preparation. In preference to horse or farmyard manure, if some fertiliser is really required, I would recommend guano, used at the rate of a handful to each square yard of ground, and forked well into the soil a week or so before planting. During growth, old soot sprinkled among the plants in showery weather will discourage slugs and other soil pests, and has a distinct effect on the colour of the flowers, heightening the red shades and purifying the tone of the deep " blues " such as Baron J. Hulot and Master Wietse.

Planting.

Time of planting depends on soil, district and prevailing weather. In the south and west of England and in warm sandy soils, the earliest planting may be made towards the end of February if the weather permits ; the Midlands and eastern counties are, naturally, later, and there the middle of March will be a more suitable season to make a start. In the north and all districts where spring comes fitfully or tardily, the weather will decide the most favourable moment ; but, wherever one is operating, it is advisable not to plant all the corms at once. Better is it to divide the stock into four or five lots, leaving an interval of ten days or so between each plantation, as this gives an extended season of bloom. Another important point to watch when planting is to plant corms which are showing a green point at once. No good results by delaying the planting of precocious corms. Dormant ones can be witheld for later plantings. Another factor tending to the extension of the flowering season is to mix some smaller corms with the large ones, the former taking about a fortnight longer to reach the flowering stage than those which are fully matured.

A DORMANT AND A PRECOCIOUS CORM.
Pointed corms should be planted at once.

Depth to Plant.

One hears many opinions expressed as to the proper depth to plant the corms. It is only common sense to plant more deeply in light soils than in heavy ; but deep planting

Digitized by Google

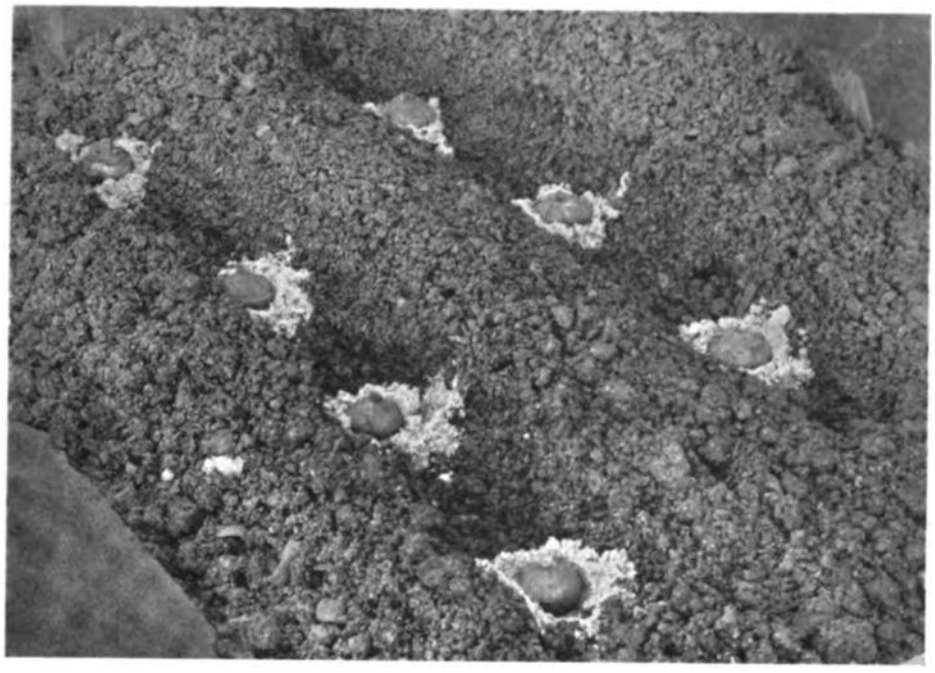
is, I feel sure, not in the best interests of the grower. Experience has frequently proved that spawn production is much heavier in cases where the corms are planted within reach of the sun's warmth during the growing season, and, where spawn is freely produced, almost invariably a plump heavy corm is the parent of that spawn. In very sandy soil, 4½ins. to 5ins. is a suitable depth; in medium loams, 3ins.; and in clay, 2ins. to 2½ins. is enough. Wherever the soil is heavy and retentive, it pays to plant the corms in an envelope of silver sand. Not only does this help to keep vermin from eating the corms, but it makes harvesting an easy, and clean operation, taking probably about a fifth part of the time that it would if messy, sticky clay has to be scraped off before the corms are ready for storing.

Some writers on gladiolus matters suggest digging before the foliage begins to turn yellow in the autumn. There is no great harm in so doing, but it can be taken as certain that so long as the leaves of deciduous plants are green they are still functioning, and I consider it is a mistake to commence digging up the corms till even a slight change of colour in the leaves indicates maturity.

Culture in the Greenhouse.

Growing gladioli in pots for greenhouse or conservatory decoration has so rapidly increased in favour that something might be said here on that phase of culture. I grow at least 1,000 corms each year in pots and have taken fairly exhaustive notes of the results attained, so that my experience may reasonably be of some help to others. Broadly speaking, the large-flowered varieties are slightly dwarfed when grown thus, while the primulinus hybrids are refined and improved.

PLANTING GLADIOLI IN POTS.
Three corms should be planted in a 9-in. pot. Note the drainage and the evenness of the compost. The corms should be about half-an-inch below the soil.



PLANTING THE CORMS.
The depth at which to plant varies with the nature of the soil, about four inches being a good average depth. Note the dressing of silver sand round the corms.

I have not found it useful to grow the large-flowered sorts in this way for exhibition purposes, but only for hybridising, though, if one went in for systematic and high feeding, excellent spikes could certainly be produced. As regards the whole range of primulinus hybrids, whether the true "prims" or medios, their cultivation in this particular manner is so thoroughly enjoyable that unlimited leisure and means for the pursuit of the hobby could not stale its infinite variety. Under pot culture the gladiolus is as easy to grow well as a tulip, and, like many of the cottage and Darwin types of that flower, the blooms opened under glass, and especially when gently forced, are frequently refined and clarified to a high degree of purity, altogether superior to those from the open border.

How to Secure Good Corms.

If the corms are to be thrown away after flowering, little heed need be given to soil, size of pots used, or actual time of potting; but these points are of considerable importance if the varieties are scarce or expensive and an economic eye is given to the increment of stock. To secure good corms and large or numerous cormels, it is essential to pot early, not later than the end of March, and earlier if possible; to use large pots; and to give plenty of nourishment for the roots. I generally put three corms in a 9in. or 9½in. pot, and the compost, prepared some time in advance, is rich and mellow without heavy manuring. If animal manure is mixed with the potting soil, it should be very old and thoroughly rotted; but an excellent compost can be made without it. The following mixture can be used safely and with good results:

12 parts decayed turfy loam of a somewhat heavy texture
4 parts leaf-mould
1 part finely ground oyster-shell
1 part silver sand.
1 part burnt wood ash
½ part bone-meal
½ part old soot.

As this is being mixed together, a handful of Peruvian guano may be added to each barrow-load of compost. All the ingredients should be thoroughly blended and the heap turned over frequently for some days before being used. One large crock is sufficient over the drainage hole of the pot. On this some of the rougher parts of the soil should be placed, and then more compost added till the pot is within 2ins. of being filled. The corms are slightly pressed into the surface, and the soil made moderately firm before filling up. When the operation is complete, the tops of the corms ought to be about half an inch below the soil, or an inch below the rim of the pot, for enough space must be left for watering.

Treatment after Planting.

If a good watering through the rose is given at once, it will suffice for at least a week, and until growth appears above ground the pots must not be over-watered. The pots should not be exposed to much frost, or rooting will be retarded; on the other hand, no forcing must be attempted until root formation is well advanced and top growth started. The best place for the pots in the early stages is a greenhouse from which frost is just excluded; or, failing that, they can be plunged in ashes up to the rims in a cold frame. As leaf growth advances it is advisable to place a 4ft. cane against each plant, taking care not to thrust it into the soil too near to the corm. When the flower stem appears, it should be secured to the cane in good time, preferably with a split ring, as raffia ties are sometimes liable to prevent upright growth by catching on some obstruction or adhering to the stem itself.

Feeding the Plants.

I begin feeding the plants when the third leaf appears, starting with very dilute doses of liquid manure every four or five days, gradually making it a little stronger and with more frequent applications, and occasionally alternating with guano water and soot water. Some growers stop all artificial feeding before the flowers begin to open, but I think this is unnecessary, and if liberal cultivation is continued till the flowers have passed and seed is ripening, the corms are all the better for it. If seed is not wanted, the spike should be cut off, either as soon as the first bloom opens, when it can be used for decoration, or immediately the beauty of the spike is past its best. In this case, feeding is continued for a fortnight or so to plump up the new corms.

J. L. GIBSON.

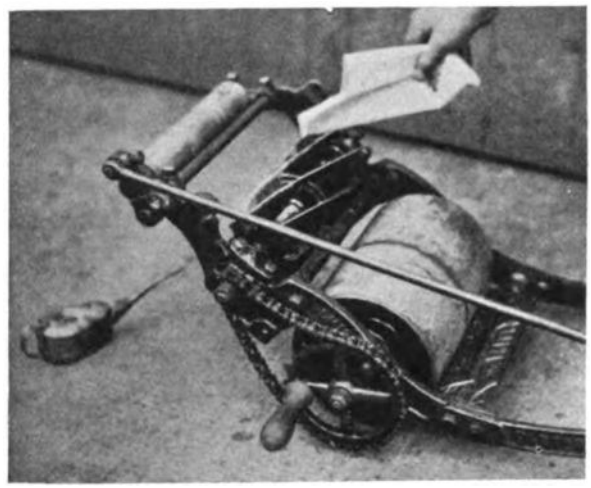
THE BUSY MAN'S PAGE

Sow Stocks for Summer Flowers.

THERE are several types of the stock, but that kind which is most commonly grown in gardens for summer bloom is the summer-flowering or ten-week stock. Plants are easily raised in a cold frame without any but sun's heat; indeed, cold culture like this gives strong robust and hardy plants for planting out in May and June. The soil should be prepared for them, because it is better to have the manurial dressing well mixed with the soil proper and to have the border uniformly enriched before they are planted out. Some old mortar rubbish or carbonate of lime may be added, along with the manure, if the ground was not limed in winter. It is best to keep young seedlings on the dry side, as they are liable to damp off in dull weather and yet the plants must never lack water; this and a check given in any other way, are potent causes of premature flowering. Always keep a reserve of plants in a spare bed to replace "singles" but in the first instance get the best seed and those singles will be very few. Among the best strains may be classed large-flowering pyramidal, Giant Perfection and the dwarf bedding kinds; also to be recommended are the newer beauty stocks which may be considered as a type of ten-week stock. Good seed gives a delightful range of colours, but, of course, growers can have individual colours to choice.



SHARPENING THE LAWN MOWER.
One handle is removed and screwed to the gear wheel, and as the latter is turned, emery powder is shaken over the blades—previously well oiled.

Care of the Lawn Mower.

IT is quite time to examine the lawn mower, as this will soon be in regular use. Overhaul the machine carefully, looking at the different parts to see if any of these are worn. The bearings of the revolving blades are the parts which are most likely to wear. Indications of this are to be found in the "jumping" of the blades when the machine is in use, and by the frame of the blades feeling very loose. In a chain-worked mower the chain may need tightening up, for in course of time this tends to become loose. The local ironmonger would be able to attend to matters of this kind, and it is as well to get the machine to him soon, so that it will be ready for use when the cutting season starts.

All lawn mowers must be sharpened now and again, and this is a job calling for extreme care. The blades should be well oiled and all the rust removed by rubbing over with a paraffin rag. Then some emery powder may be shaken over the blades, which are then revolved. Where the blades are not too blunt, this method will serve to fit them out for a further season. Where, however, the blades are in a bad condition, they should be sent to the makers or another expert for attention. The revolving blades may require some adjustment, for to work properly they should revolve very close to the fixed blade at the bottom. When this is the only trouble quite often the turns of a few screws or the manipulation of a couple of bolts will bring the blades closer to the knife. By adjusting the back roller the height of the cut is altered accordingly. The notches in the slotted brackets enable one to see the adjustment is equal on both sides.

Many gardeners make the first mowing with a scythe, and this is really quite a good idea. If a scythe is not available, the first mowing should be done with the blades of the machine set high. The height at which the machine will cut is varied by shifting the rollers up or down. Place the mower on a hard ground and it is then quite easy to see if the fixed blade is too near or too far from the ground level. When everything in the mower seems in order, oil all the bearings and rub the machine with an oily rag. One of the illustrations shows the method of oiling the bearings which, in this case, are of cast-iron. The screw head seen just behind the oil-can spout adjusts the bearing and should be tightened sufficiently to prevent any play of the cutting cylinder (the blades) without hindering its revolution. It is sometimes wise to remove the cutting cylinder and clear out all grass clippings and other *débris*.

The back roller (and, accordingly, the cut) needs to be nicely adjusted.

How to Sow Dust-Like Seeds.

ANYONE who is inexperienced in the sowing of such seeds will benefit by following the hints given in this short note. Minute seeds are, mostly, those of more valuable kinds of plants, such as calceolarias, tuberous and fibrous-rooted begonias, etc., and should not be buried under any soil. It is always safer to sow such seeds in pots or pans, than in boxes, because the soil in a pot retains its moisture longer than in a box. If once, only, dust-like seeds become dry in the soil after germination has begun, they will perish. There is more moisture round large seeds because they are buried under a thin layer of soil. Avoid sowing such seeds thickly. The seed leaves of the resultant seedlings are large, especially those of gloxinias and tuberous begonias, and if they are overcrowded, there is danger of wholesale damping-off and the weakening of every individual seedling. Wash and thoroughly dry the seed pans or pots, also crocks. Provide sound drainage by neatly placing the crocks in position and then a few half-decayed leaves on them, or some very fibrous turf, quite old and from which the fine soil has been sifted. The bulk of the soil should be passed through a rather fine meshed sieve. It should not be too wet nor too dry at the time. Make the surface level and carefully water through a fine rosed watering can. When the surface is beginning to dry a little sprinkle a small quantity of white silver sand on it. Then sow the seeds very carefully and very thinly. As the soil dries further the dust-like seeds are drawn into its surface and are, as it were, fastened down there. This is all that is required. Do not put on soil of any kind, however light; but cover the pot or pan with a sheet of glass and some brown paper. Try to keep the soil in the pan in a consistant state of moisture by placing it out of the direct rays of the sun. If water is required, immerse the pan gently in tepid water, and, also, while the seedlings are tiny.

The Lawn in the Early Spring.

FROM the beginning of March onwards the lawn requires an increasing amount of attention. The worms are getting active, and their casts should, on dry days be regularly scattered with a birch broom. Then, unless the lawn is in a sodden state, roll thoroughly. Where the worms are very abundant so that their operations really disfigure the lawn, apply clear lime water in the evening and gather the worms on the following morning; or apply one or other of the artificial worm-killers which are all very effective. Apply lawn sand also, in the proportions directed. There are several good brands obtainable.

To ensure easy running the cutter bearings must be oiled regularly.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Gay Flowers for the Town Garden.

ABOUT 120 species of gladioli are known to botanists. Their central home is South Africa, but species are found wild as far afield as Turkey and Greece, and one even occurs wild in this country. This is Gladiolus illyricus, and is only known in three localities. In South Africa it is not uncommon to see fields of gladioli spikes, as plentiful as buttercups and daisies are in this country. What a stirring sight it must be to see a whole field of waving gladioli! I was hardly surprised when a friend from South Africa told me recently that he used, a few years back, to take parties of visitors up the Table Mountain specially to see the wild gladioli, a sight, he declared, never to be forgotten.

It is safe to say that no flower has become more popular in so short a time as the gladiolus. There is, as usual, a very good reason for this popularity. Easy culture and certainty of results are the reasons for its universal cultivation. No matter whether the garden be in the heart of a smoky town or in less smoky suburbs, the result is the same, a glorious display of bloom. But to get the best results a certain amount of care is needed. The important point in all town gardens is thoroughly to prepare the soil. Good drainage is essential. Deep digging, stirring the soil to at least 18ins. promotes drainage and soil aeration in most cases, but if the land is very heavy and waterlogged, some sort of drainage must be made. In the small garden this can be effected by digging a trench across the flower border about 3ft. deep. Into the bottom of this place a 6in. layer of bricks, clinkers, or rough stones. An application of lime is also important. Spread 4oz. of ordinary builder's lime over each square yard before digging is commenced. To a light soil add leaves, organic refuse and other moisture retaining contents; to a heavy soil apply sand, road grit (if free from tarry matter) or mortar rubble. Use a dressing of one of the proprietary fertilisers suitable for flower production when planting and again when the shoots are 6ins. high.

A word about planting. If the corms of gladioli can be started into growth in boxes of light soil in a cold frame, well and good. But this is not essential. They can be planted direct into their flowering quarters. A good plan for ease in planting is to rake the bed or border level, breaking up any lumps in the operation. Do not remove small stones, they aid drainage. Sprinkle a little sand over the surface, and lay the corms out 6ins. apart or a little more, according to the kind. Plant with the flat-ended dibber if the soil is light, but if the soil is heavy clay, use a trowel. Allow a little of the sand or grit to trickle into each hole before inserting the corm. Plant 4ins. or 5ins. deep. Cover by raking the surface over. Gladioli are best planted in masses, and owing to their stiff habit are best associated with other, more bushy plants, such as snapdragons. Endless colour schemes can be devised. Complementary colours go well together. For example, yellow snapdragons with deep purple gladioli.

Varieties are Legion.

There are too many varieties of gladioli. The amateur goes to a show, and probably makes a note of one or two choice sorts and maybe forgets the particular nurseryman who exhibited them. When planting time comes he consults the catalogue of a leading seedsman, only to discover that no mention is made of the variety noted at the show. What is required is standardisation of the best varieties, and to some extent this is happening, but there is considerable room for improvement. The following are some of the best modern varieties: Baron Hulot, deep violet blue with small white stripes; Pink Perfection; Halley, light salmon, throat and portion of three lower segments flushed sulphur, with magenta markings; Brenchleyensis, handsome spikes of vermilion scarlet; Golden West, orange scarlet, creamy yellow blotches; L'Immaculee, white; Yellow Hammer, clear yellow.

Those who prefer mixtures should plant some of each of the following hybrids, gandavensis, the famous Langprim, Lemoinei, primulinus, and Childsii. These will give a variety and succession of blooms. For show purposes it is best to plant named varieties.

LARGE FLOWERING GLADIOLI ASSOCIATE WELL WITH OTHER FLOWERS IN A ROUND BED SUCH AS THIS. UNDER TOWN CONDITIONS THEY SUCCEED PARTICULARLY WELL.

Sparrows and Seedlings.

SEEDLINGS often come to grief in town gardens because of the sparrows which attack them. To cover them with wire netting, or twigs, until they are well grown is one way of avoiding trouble. A few sticks driven into the ground, and black thread stretched across and across the seed bed and fastened to the sticks is most effective in scaring away the intruders.

Where sparrows are known to be exceptionally troublesome it is well to take every precaution. First of all sow the seed rather thickly (in the case of lawn seed, for instance), to allow for a percentage of loss. In addition, place a shallow dish of water for the birds to drink here and there in the garden. In dry weather birds frequently peck at young green shoots for no reason other than that of thirst.

How to Mix Potting Soil.

PROPERLY mixed potting soil is a pleasure to handle. It is silky to the touch and a rich brown in colour. Close inspection reveals flakes of dead leaves, bits of brown earth (loam), and particles of sand. If you need only a little soil for potting, it may be bought from a florist, but it is quite easy to mix at home and, of course, cheaper. Loam is made by taking the surface turf from pasture (or road sides) and building it into a heap to remain until the grass decays. After about six months this is chopped up with a spade and mixed with decayed leaves and sand, the proportion varying according to the kind of plants to be grown in the pots. Bulbs like two parts loam, one part leaves, and one part sand. Chrysanthemums like two parts of loam, one part of decayed leaves, one part of well decayed manure, and a handful each of bone meal, lime and sand to each bushel of the soil. It is always a good guide to the mixing of potting soil to study the nature of the soil in which the plants grow naturally. For example, carnations grow in the wild state on limestone, and in mixing any soil for them, lime must be added in liberal quantities.

Dahlias for the Town Garden.

DAHLIAS which have been stored for the winter should be put into boxes with a little moist earth, and kept away from frosts. They will make shoots, just as potatoes do that are stood on end to sprout, and, if desired, each shoot can be cut with a piece of the rootstock attached, and planted in a pot. By the time the frosts are over, the plant will be well established and will make a welcome addition to the border. A single plant of a good dahlia makes an outstanding feature in a small garden.

The following varieties are suitable for town cultivation: Nora Bell, scarlet and yellow; Our Annie, shrimp pink and yellow; Lemur, bright scarlet with bronzy foliage; Aglaia, orange and salmon; Trevussa, orange and red; Picture, orange tipped with rose; Pink Pearl, rose pink; Crimson Flag; Coltness Gem, bright scarlet; and Dobbie's Bedder, pale sulphur.

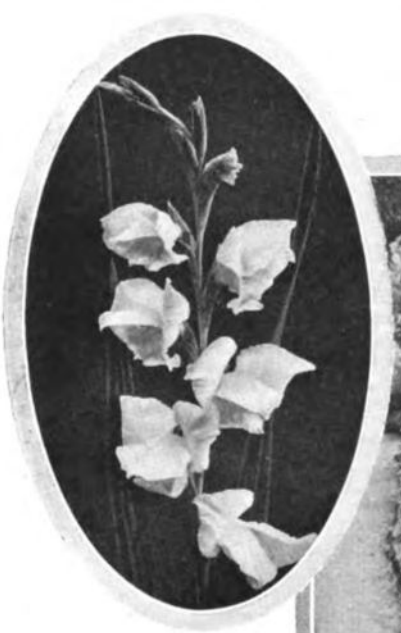
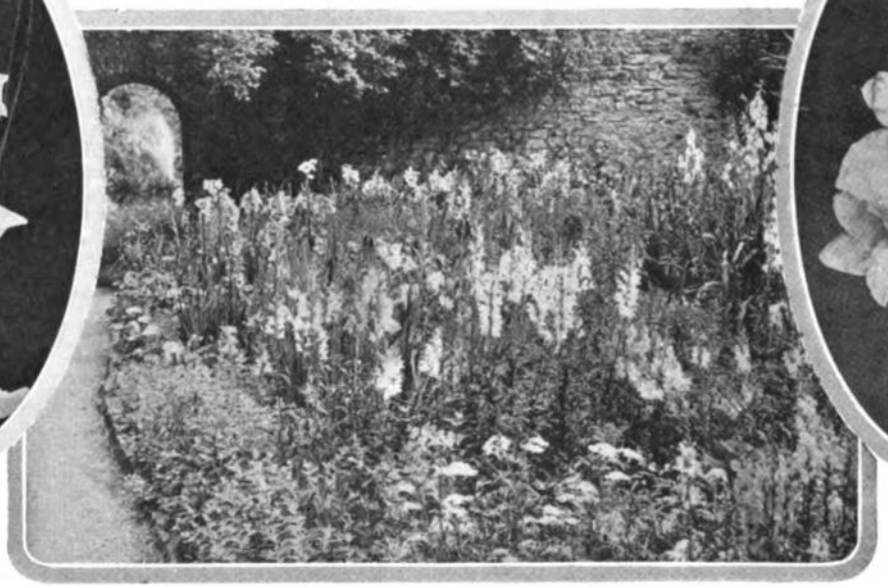
GLADIOLI FOR EVERY GARDEN

This gorgeous flower should be planted within the next two or three weeks for a brilliant display in the summer.



THE DAINTY AND HOODED PRIMULINUS TYPE.



THE STIFF AND ELEGANT LARGE-FLOWERED TYPE.

GLADIOLI GIVE DIGNITY TO THE LATE SUMMER BORDER.

In this article an authority on gladioli gives, at our request, two lists of varieties for present planting. (1) The best dozen primulinus hybrids; (2) The best dozen large-flowered varieties. These varieties have been specially selected for the needs of the amateur. They offer a wide range in colour and habit and are reasonable in price.

Primulinus Varieties.

THE primulinus hybrid class of gladioli is, comparatively speaking, a new one, yet there are, I think, sound reasons why this light, graceful and altogether charming class will become most popular. There are already in commerce many exceedingly beautiful primulinus hybrid varieties (shall we call them prims. for short?) and the distinct promise of still finer ones to come. As a class, prims. are remarkable for their light and "airy" appearance, their superb colours and the ease with which they lend themselves to all forms of indoor floral decoration. A curious point with respect to their colouring is that, although their colours range from white to deep scarlet through many shades of cream, yellow, pink, salmon, orange-salmon, orange and orange-scarlet, one may mix a dozen or more varieties in a decoration and there will be no appreciable sign of any one shade clashing with another. I very much doubt whether such glorious art shades of salmon and orange are to be found in any other species of flower except, perhaps, in begonias, but the latter do not possess the combinations of yellow and salmon found in prims. such as Salmon Beauty.

Here are twelve reliable and excellent varieties which should not cost more than 25s. for twelve corms of each (144 in all): Athalia, Daphne, Hermione, Maiden's Blush, Niobe, Orange Brilliant, Orange Queen, Rosandra, Salmon Beauty, Salmonea, Souvenir and Xanthia. I will briefly describe them.

Athalia.—Undoubtedly the best brilliant orange-scarlet, a very beautiful variety.

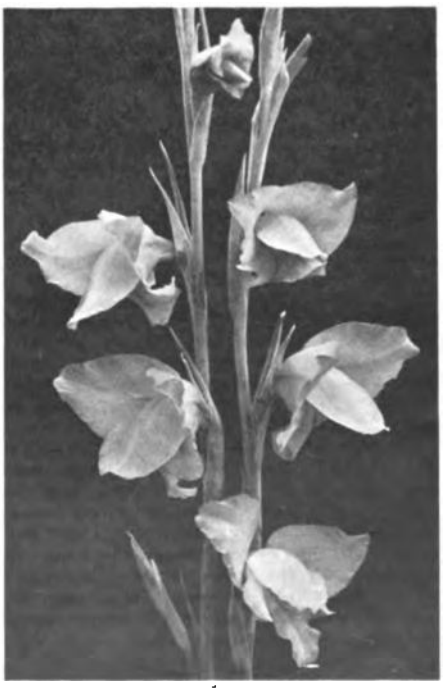
Daphne.—A wonderfully rich scarlet-red or brick red.

Hermione.—One of the earliest of the prims. to be named and introduced, but still one of the best. A pleasing shade of orange-salmon.

Maiden's Blush.—Easily the best inexpensive pink prim., it should be included in every collection.

Niobe.—A very reliable variety. A distinct and beautiful orange self.

Orange Brilliant.—The colour blending is very attractive. Its upper petals are orange shaded scarlet, and the lower yellow shaded orange. A small-flowered and dainty bicolor exceedingly useful for decorations.



DAPHNE, A DAINTY AND ATTRACTIVE PRIM. OF A RICH SCARLET RED SHADE.

Orange Queen.—There is no other gladiolus, either in the large-flowering section or among the prims., quite like Orange Queen in tone of colouring, which is a charming shade of warm, coppery orange. As yet it is not very well known, but is sure to become popular. For a primulinus hybrid its flowers are rather on the large side and perhaps a little too close together on the stem, but its most wonderful colour fully compensates for other slight defects in form.

Rosandra.—A good grower and very reliable. Probably the best soft rosy cerise.

Salmon Beauty.—In my opinion the best primulinus hybrid gladiolus. Its habit of growth and form leave nothing to be desired. The colouring is exquisite, soft warm salmon with a yellow-tinted throat. Whether growing outside or used for indoor decoration, both in daylight and artificial light, this variety invariably attracts attention. It should be grown by all.

Salmonea.—Another excellent decorative prim. and one of the most beautiful of all. Salmon, flushed glowing orange.

Souvenir.—The best and most inexpensive bright yellow. A strong grower and a colour which "sets off" any of the deep orange and salmon shades to perfection.

Xanthia.—The rich vivid golden effect of Xanthia in the bunch is most effective. It is a brilliant, pure orange which I most strongly recommend in preference to the better-known and very popular Sphinx.

A few others of great merit, most of them a little more expensive than the above dozen are: *Altair*, a distinct salmon-saffron, with flowers a trifle on the large side. *Citronella*, a very refined creamy yellow self, pure and clean; invaluable for decorations. *L'Ecaillon*, a very soft biscuit salmon with rose blotch,

Digitized by Google

delicate and distinct. A very beautiful prim. *L'Exuette*, cherry red with large and well defined golden blotch. A little larger bloomed, but a very striking variety, particularly in the bunch. *L'Yser*, something like L'Exuette, but brighter. Orange-scarlet with yellow throat. *Rose Luisante*, a very fine rose-pink, a good grower, rather large flowered. *Scarlet Cardinal*, without doubt this is the best intense and brilliant scarlet primulinus hybrid. Of ideal form and habit. *Shell Pink*.—This new variety is certain to become very popular when its price is a little lower. It is the best pink I have yet grown.

Large-Flowered Gladioli.

The extraordinary number of varieties of large-flowering gladioli presents no small problem to the inexperienced amateur who may wish to grow really good ones but who is unable to pay "fancy" prices for them. New varieties are not necessarily the best, nor are prices always a reliable guide to the merit of a variety. The inexpensive kinds are usually the older ones, but it is quite possible to find among these a fair number of satisfactory all-round varieties which will hold their own for beauty and reliability against later introductions.

I will venture to name a dozen or more which are not likely to be beyond the reach of even a modest purse.

My dozen are Baron Hulot, Byron L. Smith, Early Sunrise, Golden West, Mrs. Frank Pendleton, Odin, Parliament, Pink Perfection, Prince of Wales, Red Emperor, White Giant and Yellow Hammer, all distinct colours and all obtainable from advertisers in THE GARDEN. In the first place, the cost of the above collection, twelve top size corms of each variety (144 in all) should be between 25s. and 30s. at the most.

Now for a few details about them which may be perhaps interesting and useful. Their time of flowering varies slightly, and as a guide to this I am placing "E" after the name of each variety which blooms early, "M" after each mid-season kind and "L" to indicate one that is later still.

Baron Hulot (M).—The well known deep blue and still one of the best in its particular shade. It is fairly vigorous, but, like almost all blues, the flowers are on the small side.

Byron L. Smith (M).—A distinct and beautiful variety. The colour is very similar to a Cattleya orchid, lavender pink with creamy throat blotch. One needs several spikes together to obtain the full beauty of this gladiolus.

Early Sunrise (E).—One of the finest gladioli in existence and most reliable. A vigorous grower, producing long, well shaped spikes with many florets open at the same time. Extra large-flowered and a most pleasing salmony pink colour.

Golden West (M).—Almost as large as Early Sunrise, a beautiful orange-red, overlaid gold. It is a good grower, giving a good well formed spike. Its beautiful and unusual golden markings invariably attract attention.

Mrs. Frank Pendleton (M).—I prefer this variety to Willie Wigman; their colours are, of course, quite different, but in general effect there is a resemblance caused by the dark blotch on both. Mrs. Frank Pendleton is a light pink with a dark blotch, very striking and distinct in the bunch.

Odin (E).—Orange-salmon with darker, well defined blotch, a tall, vigorous grower, giving a handsome spike of a rich colour.

Parliament (L).—A charming shade of salmon-rose with very large flowers.

Pink Perfection (L).—Although quite inexpensive, this is one of the finest soft pinks we have, a most satisfactory gladiolus.

Prince of Wales (E).—Very few gladioli are cheaper than Prince of Wales, yet it is still the best salmon-pink, and a great favourite with all. At the British Gladiolus Society's Exhibition at Burton-on-Trent this year it was in evidence on many of the trade groups.

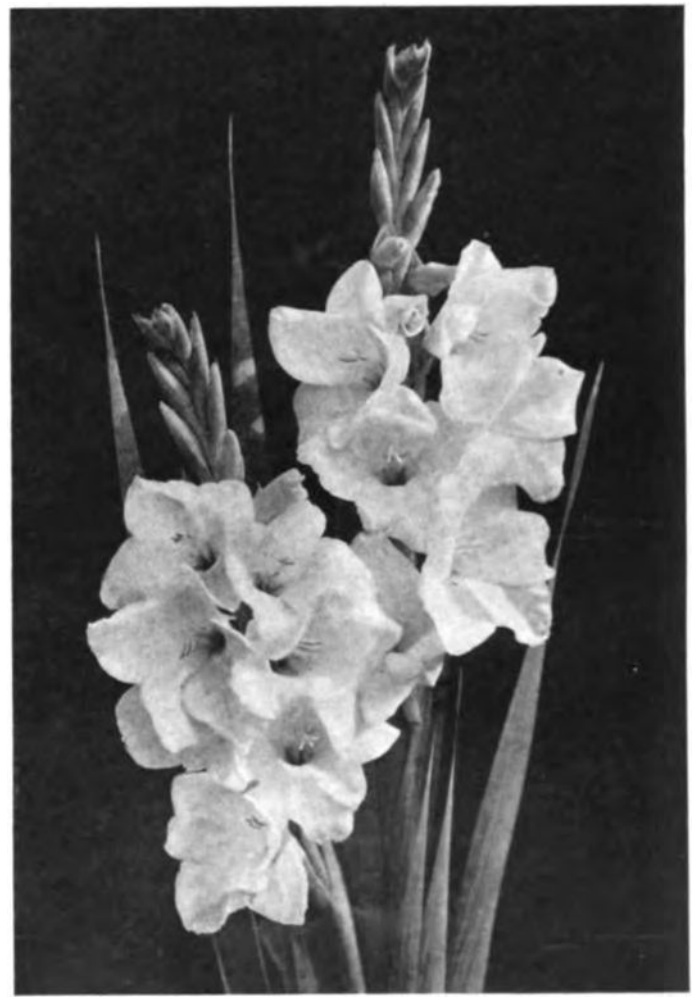
Red Emperor (M).—A basket or large bowl of Red Emperor well arranged is a sight that lives in the memory for a long time. It is very vigorous, extremely large-flowered, and the most popular red in commerce at a reasonable figure. Red Emperor is the favourite gladiolus of many.

White Giant (M).—Large bloomed and well known. It is the most popular white, and the white variety usually grown for market purposes and seen in the florists' windows.

Yellow Hammer (M).—Extra vigorous and undoubtedly the best inexpensive yellow.

C. H. A. S.

GLADIOLUS WHITE GIANT, A MOST POPULAR AND ATTRACTIVE VARIETY.
This is the one usually seen in florists' windows.



THE DISTINCT AND BEAUTIFUL BYRON L. SMITH, OF A BLENDED COLOUR OF LAVENDER PINK AND CREAM.
Two or three spikes look well together.

SOME OF THE BEST ANNUALS

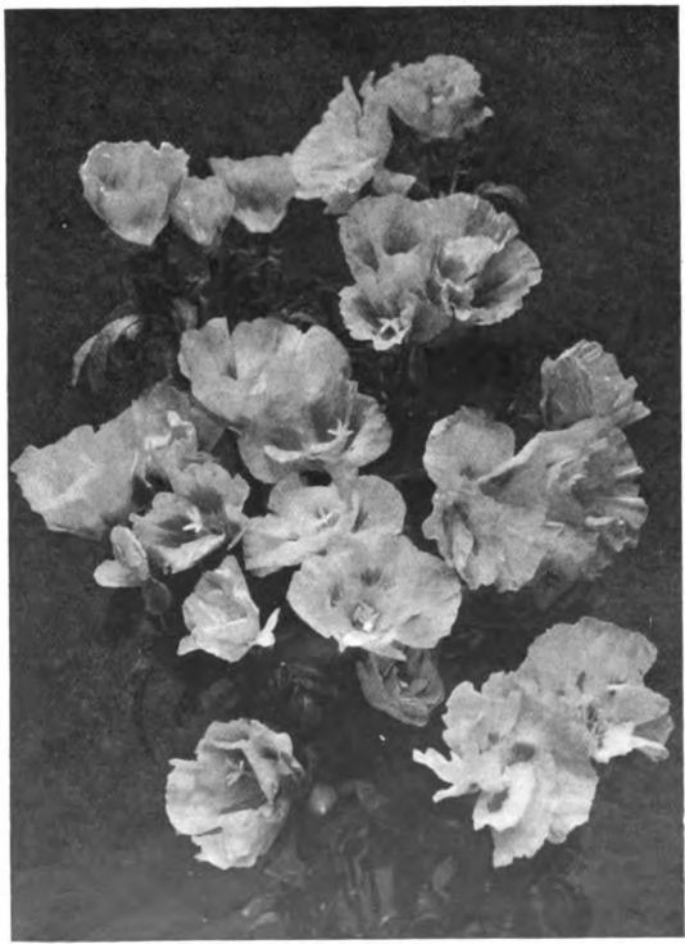
AMONG the lists of our seed catalogues we have a large and varied choice; but within the short space available I am merely going to mention a few of the best for cut blooms and some of those that will give us blooms from early summer until late autumn confining myself to those that are true annuals, that is, necessitating the sowing of fresh seed each spring. We will start with the

Aster, whose splendour is only marred by those heavy summer thunder showers to which our climate is so subject. Here we have choice of many sorts, including the Comet, ostrich plume, peony-flowered, the large bold single varieties and the Victoria. The flowers are very easily grown from seed sown in March or April in prepared beds made up in a cold frame, or in pans or boxes placed on a greenhouse shelf. Soil for sowing should be a mixture of finely sifted loam, leaf-mould and sharp sand. If the boxes are covered with a piece of glass, it will hasten germination. Seed pans should be watered by immersion before sowing seed. When seedlings have made a good start, they may be pricked out into a larger space. If shelter can be given at night for a time, they may be put out into a prepared bed in the nursery garden; by about June they will be ready for final beds.

Schizanthus (Butterfly Flowers).—These are splendid for vase work if well grown. Where there is a greenhouse, seed is sown in August and September in large pots, and the plants grown on through the winter for blooming in the conservatory in spring. For outside work and cut flowers seed may be sown in March–April in the positions where plants are required to flower, as they do not transplant well unless pot grown. They like a well drained moist soil, and the incorporation of well decayed-manure is an added encouragement.

Salpiglossis.—These are both varied in colour and elegant in growth, the one and only fault being the sticky nature of the leaves, etc., in this respect akin to their close relative the petunia; but this trouble does not in any manner spoil the flowers, and they are unsurpassed for cutting for vases. They are sometimes grown in the greenhouse for spring blooms, but on these lines need careful attention to the foliage, etc., being apt to become very blighted under glass; in fact, not worth the trouble. For outside work the seed may be sown in March in pans or boxes placed in frames. Prick out when large enough to handle and, finally, plant in permanent quarters in latter part of May. If, as in many cases, there is no glass available, seed sowing may be postponed until April, and then be sown in its flowering position. An extra good point about these flowers is the wonderful display of bloom right up until the end of October under mild conditions. They stand a considerable amount of drought; in fact, if watered, are inclined to scorch and shrivel.

FEW PLANTS HAVE THE CHARM AND GRACE OF THE NIGELLA WITH ITS OLD-FASHIONED NAME OF LOVE-IN-A-MIST.
They are still considered as one of the best of the blue annuals.



THE CHARMING PINK GODETIA CAN BE GROWN IN CLUMPS IN THE FRONT OF THE HERBACEOUS BORDER.

Godetias.—Here we have a real hardy annual, needing no glass shelter at all. It may be sown straight outside in flowering quarters in May or end of April. There are now obtainable named varieties, as well as double sorts, and all these are splendid for cutting, and look well in clumps or lines in front of the herbaceous border. They like a good deep soil, and under these conditions stand hot, dry weather well. It is true they are rather a heavy type of flower for cutting, but for a gay garden they are excellent and last well.

Stocks.—Under this heading I shall only deal with the variety termed the ten weeks stock as being a true annual. Almost too well known to need description, they may be sown under glass in March and pricked out into larger boxes when large enough. Being of the crucifer type, they are gross feeders, and therefore require well manured ground of a fairly light nature. Again rather a heavy type of bloom, but they look well cut in vases with such as gypsophila. From the florist's point of view only the double varieties are of any use, but this cannot always be arranged, and the best safeguard is to obtain seed from only well known firms, of which there are plenty nowadays.

Nigella (Love-in-a-Mist).—This is certainly one of the best annuals we have, yet so few grow it. Splendid for late flowering, especially on a limestone soil. Miss Jekyll is the best known variety, being intense blue in colour, the foliage in all cases being an added adornment—a dark green ferny-like foliage. May be sown outside in April where it is to bloom. It usually seeds itself abundantly, thus effecting a saving on the seed bill.

Larkspur (*Annual*).—It always surprises me that these are not more widely grown, having all in their favour now due to improved strains, as well as the double variety, and being elegant, easy to grow and flowering until late in the season. They do not require glass shelter, may be sown outside in April, being

Digitized by Google

thinned if required. I suppose some would find a fault in the lack of any scent, but surely the colours make up for this.

Centaurea (Cornflower and Sweet Sultan).—Here we have two members of a family, both equally good. The cornflower is best in the old blue colour, of which there is also a double variety now. This annual, with some good foliage, is excellent for decorating tables. Sweet sultans, are varied in colour, well known for their honey-like smell. They look well as cut flowers mixed with something else, but are too stiff alone. Both these annuals may be sown outside in permanent quarters in April, and will give a display of bloom until late autumn.

Coreopsis.—In this we have a splendid annual to cut from in both summer and autumn. There are both yellow and red varieties. It will do well in a dry position and comparatively poor soil, too. Seed may be sown outside either in rows or groups in April and May. I once saw this annual flowering among a large bed of roses. The seed had evidently been in some burnt rubbish that had been spread over the garden broadcast. The effect was splendid and flowers were cut right up to the time of the first frost. I may add that these old-fashioned flowers are excellent for table decoration at the autumn shows. If once allowed to seed, it will usually come each year afterwards.

Cosmos.—These were once of a rather ugly colour of a mauve shade, but now improved strains have given us a variety, and a mass of these flowers look splendid in a large round bed, the dark green ferny-like foliage adding greatly to the general effect. Seed is often sown straight outside in April–May, but stronger plants are obtained by sowing, if possible, under glass and pricking off as required. They are suited to a dry and even poor soil, and flower until late season.

Shirley Poppies.—These I feel I must mention, though too well known to need description. They are quite hardy, no glass being required at all. Sow early April and May, or even in March if a warm spring. They are certainly the most delicate and graceful of our annuals. One gets a wonderful range of colours from a packet of mixed seeds from a good firm, with often many double flowers as well. They are quite unsurpassed for table decoration at shows, and a well arranged table of these seldom fails to catch the judges' eye. The great secret is to pick them before quite out in flower and during the cooler hours of the day. They self-sow largely each year.

Clarkia.—This annual is perfectly hardy. It is valuable for filling in gaps in the front of a herbaceous border, and also for growing in the reserve garden for cutting purposes. It is also largely used for conservatory decoration, when it is sown in pots in the autumn for blooming in the spring. The long graceful sprays of double or semi-double flowers are most decorative, and are produced in great abundance. It should be sown thinly in April, where it is to flower, thinned rigorously and given slight support by means of short, bushy twigs.

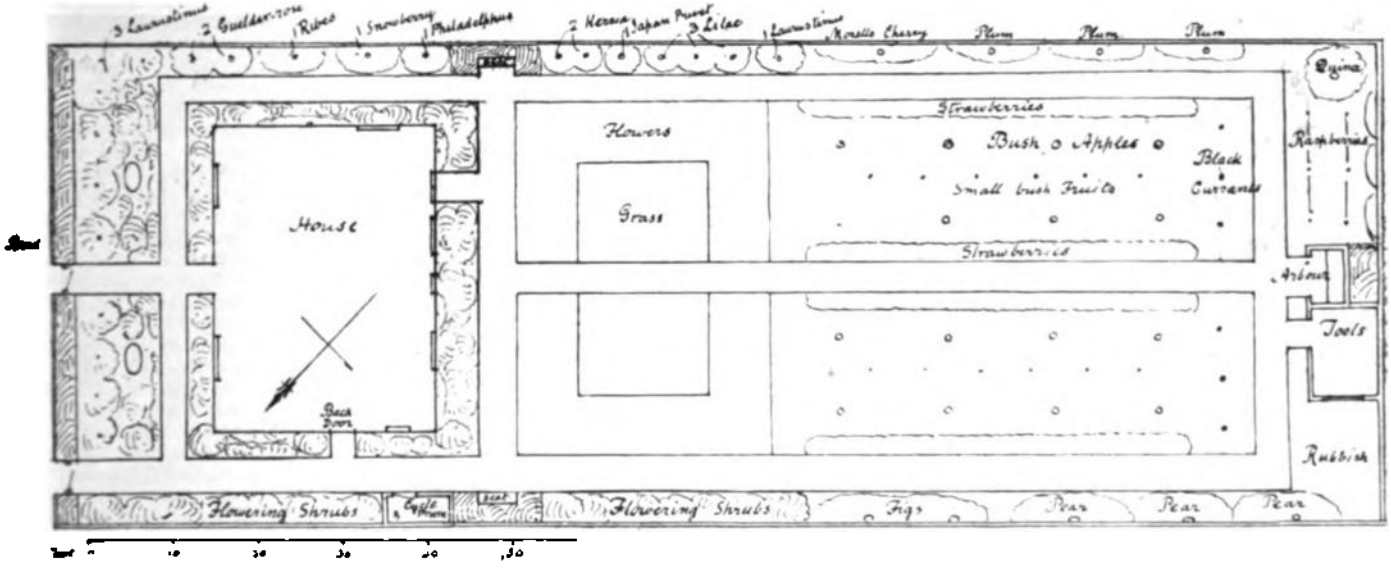
Scabious (Pincushion Flower).—As a last mention I appeal to lovers of a gay garden to grow scabious. Usually sown under glass and when large enough pricked out into their flowering quarters, but good results are also obtained by sowing outside, as they are quite hardy. Allow a little more room than for most annuals, as they grow large and bushy.

There are many others I would like to mention, but think I have named some of the best, and space allows of no more. Therefore it is to be hoped that those wanting a gay garden will try each one of those dealt with. W. W.

THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

THIS is a small plot, 150ft. deep with a 55ft. frontage. The house stands rather near the road, so that instead of the more usual grass plat, the space is given to shrubs and flowers. There is the usual hedge next to the road, and as the extreme front has a north-eastern exposure, there are some good sized bushes of the cheerful looking Scotch Gold Holly. These will be only slightly trimmed, just enough to keep them in good shape, but they will be allowed to go up to a height of 12ft. in order to make a complete screen to the road. The ground is a good rich loam, such as will favour the beautiful white lily (L. candidum). Groups of six each are in the two patches shown by ovals and will give important points of interest to this small piece of garden. The remainder of the space has plants and shrubs, mostly of permanent foliage; dwarf veronicas and skimmia towards the back, with Cotoneaster microphylla near the front and broad leaved saxifrage (Megasea cordifolia) and London Pride next to the path. This will still leave room for some more flowers; the white Campanula macrantha and C. persicifolia, with a few Michaelmas daisies next to the hollies. The planting of the narrow border against the house is of the same character, of shrubby things for the most part.



The right and left boundaries are a wooden fence 6ft. high. On the south-west side a set of rectangular flower borders look well, and there is a well chosen planting of flowering shrubs on each side against the outer fence. They are named on one side to show the class of planting, which is repeated, with some additions or omissions, on the opposite side.

The owner's chief pleasure in the garden is fruit growing, and all the main lower part of the ground is given to it. In each of the two larger spaces there are eight bush apples, with a row of small fruit bushes, gooseberries and currants, in the middle, and borders of strawberries along the edges. Black currants, which take more space than the other small bush fruits are across the ends. This place is the more suitable for them as the ground at this end has a slight slope downwards and therefore lies cooler and a little damper. It would be tempting to have the apples alone, in a setting of grass, in which daffodils and fritillaries could be grown, but though this would be prettier gardening, it is better for the apples to be without the grass for at least five or six years.

The southern angle suits the quince, which is not only a beautiful small tree, but gives fruit for the making of a delicious jelly. Its shade will be a comfort to the two rows of raspberries for in this wild state they are woodland plants. This space is also utilised for three bushes of red currants trained against the fence; easy to mat up and keep for some weeks for late use.

Digitized by Google

RASPBERRIES FOR THE SMALL GARDEN

THERE are not many gardens or allotments that do not contain a few rows of raspberries. They are easily grown and thrive in most soils and situations and with proper care and attention will give a plentiful supply of luscious fruit over a long period. Although autumn is undoubtedly the best time to make a new plantation, spring planting will prove quite successful.

A good position to grow raspberries is on a north border, where they will be partly shaded, and if well manured will continue to fruit until the autumn.

When replanting, select canes from a young plantation, they will give more vigorous

RASPBERRY LLOYD GEORGE, A STRONG HEALTHY GROWER AND A GOOD FRUITER.
It should be planted in every garden.

growth and remain in a fruiting condition over a greater number of years than if suckers are taken from an old stock. The rows should be 4ft. to 5ft. apart, according to available space and 12ins. to 15ins. between the stools. A liberal dressing of well decayed farmyard manure must be given, especially if the soil is poor, and applied below and above the roots, but not actually touching them. It must be remembered that the raspberry is essentially a surface rooting plant, the fibrous roots must therefore be protected from drought and drying winds during the early part of the summer, when the plants are throwing up their young canes. Suckers that are transplanted in spring should be cut down to within 12ins. from the ground one month after planting, so that the stools produce strong young canes for fruiting the following season.

It is also advisable to give a dressing of nitrate of lime early in April at the rate of 1lb. to 100ft. of a row. This nitrogenous manure stimulates the young canes, and assists the laterals in old plantations to make growth before coming into flower.

Varieties.

Many and varied are the varieties of raspberries. We have summer and autumn fruiters, also red and yellow fruiting varieties. If we take Perthshire and Forfarshire as the raspberry growing area of Great Britain, we will find a trio of favourites, Mitchell's Seedling, Red Antwerp and Lloyd George.

Although those varieties are extensively grown in the open field, they will also succeed in gardens and allotments.

Mitchell's Seedling is a strong grower, producing vigorous canes with large leaves. The fruit is a beautiful scarlet, large, but slightly acid in flavour, perhaps, for dessert, but a splendid variety for culinary purposes.

Red Antwerp is an old variety, weak grower but the plants throw many suckers, with the result that the stools are inclined to spread and rise out of the ground. The fruit is very dark red, large and very sweet. One of the finest for dessert purposes.

Lloyd George is a comparatively new variety, strong, healthy grower. The fruit is large crimson, delicious flavour. Splendid dessert raspberry. This variety is being extensively planted in the fruit growing areas and is very popular. It is suitable either as a summer or autumn fruiter.

Hornet is an old variety which is again coming into commerce. Tall grower and one which succeeds on light soils. Fruit large, oval in shape and fine flavour.

The Devon is a strong grower; fruit large and slightly conical in shape. Beautiful scarlet coloured berry and fine flavour.

Pine's Royal is a vigorous grower, inclined to branch and for that reason should be planted fairly wide apart. Fruit large and of lovely dark red colour.

If, however, two varieties are to be grown in gardens, I would vote for Lloyd George as a dessert raspberry and Mitchell's Seedling for culinary use. G. S.

WHAT OUR READERS SAY

GENTIANA ACAULIS IN THE MERSEY VALLEY.

SIR,—Our first flower of the winter was the ever-beautiful Gentiana acaulis. This gem of the Alpine flora came into bloom December 26th. Each year these plants never fail to flower about Christmas time. I do not think Gentiana acaulis is grown as frequently in our northern gardens as one would desire.

If the proper conditions are considered there is no great difficulty in flowering. And what handsome bells, or are they trumpets? Here they grow in a border at the foot of a high wall, in sandy gritty soil and rough leaf-mould, with rough sandstones mixed with the soil, tightly wedged with larger red sandstones.

I am persuaded that if these conditions are carried out there will be flowers in abundance and rapid increase, and in a few years' time from planting it will be necessary to take up the original specimens, divide and replant. By this easy method we shall have a border of alpine flowers very little inferior to those grown in the Alps.

The bells measured exactly 2ins. long and 1½ins. across from point to point; the colour rich dark azure blue. Some of the flowers were taken into the house, placed in a shallow bowl, where they remained in good condition for over fourteen days.

Need I say more to induce a wider cultivation of this exquisitely beautiful flower of the Alps!—MERSEY VALE.

THE BRITISH CARNATION SHOW.

SIR,—With reference to your interesting note in connection with the £100 Gold Cup offered at our next show, it may be of interest to record the fact that amateur members of the Society are competing for a £5 prize offered for one bloom.

Carnation growers who are amateurs and would like to compete in this class, which carries a record premium for one bloom, have still time to enter by becoming members of the Society and by sending their names to me.—LAURENCE J. COOK, *Drapers Road, Enfield.*

MAKING A NEW GARDEN.

SIR,—Made bold by the letters you continue to receive asking for advice upon rockwork and plants, often for shady positions, I feel a small record of my struggles may be useful.

I have in my garden a slope from one lawn to another, about 6ft. high, facing east and north, not a promising aspect. When I knew it first it was clothed with privet, ivy and coarse grass. Although only quite a beginner at gardening, I knew something might be done to use the slope to better advantage, so I had it cleared. Then I dotted it with such odd pieces of stone as I could find, and after this planted it with the rampant covering plants one's neighbours readily give, such as arabis, cerastium and woodruff.

With more experience and much reading of THE GARDEN, I was soon dissatisfied with this, so to pieces it came again, and I faced all my disadvantages and wondered how I could overcome them. No proper stone, bad aspect, very heavy clay soil and the line of the slope very ugly. Not a promising prospect, but I started to rebuild in the following way:

I made a brick wall 3ft. high at the base of the slope, planting as I worked with primulas, saxifrages, aquilegia, ramondia, tiarella, ferns, Omphalodes verna and cappadocica, epimedium, forget-me-nots, etc. I had to dig the soil deeply and put in much broken brick for drainage, and add leaf-soil, sand and small stones to lighten it. At the 3ft. level the soil runs back like a table for 2ft., then the slope continues to the top as a rock bank. Requiring fewer pieces of stone, I was able to select the most shapely, and by burying them well and keeping to regular strata form, the effect is unpretentious and good. The table piece is at such a convenient level, it is just the place for small plants, and they can be coddled with buried pieces of stone at their roots. I have here Kabschia saxifrages, cyclamen with tiny ferns, the shade-loving gentians, campanulas, trilliums, Oxalis adenophylla, pulmonarias, soldanellas, sisyrinchium, Silene alpestris, pyrola, maianthemum, and more primulas, small bulbs and anemones.

The sloping bank is planted with stronger saxifrages, campanulas, hellebores, polygonum, vaccinifolium, iberis, astilbe, Cardamine trifolia, Daphnes Cneorum and Blagayana, small cotoneasters and berberis. At the top there is a narrow border where the sun-lovers are planted, Cytisus kewensis and Andreana compacta, lavender, yucca, santolina, perovskia and other berberis, making a graceful crown to the bank. The bricks used to build the wall were

Digitized by Google

old ones I was able to buy locally, so, without much expense and a poor start, I now have a home for plants which are a joy to care for, besides which the altered line has improved the garden. In the middle I made shallow steps of cement, with bricks as risers and the treads marked to look like stone slabs, and on these tiny plants—Erinus alpinus, wee campanulas, thymes and mosses—have made their homes. The steps, and the wall particularly, seem to be the Mecca for the seeds which grow rampageously if allowed. So I have learned not to despair if good stone is unattainable—bricks and odd pieces *can* be used to good purpose.—(Mrs.) A. B. WALTERS, *Sudbury, Suffolk.*

[We congratulate our correspondent in having made what is, according to the description, a very successful garden and one which promises to become more attractive and decorative every year once the plants are established. This account may serve to stimulate and encourage many other readers who find themselves dissatisfied with their present gardens.—ED.]

CHRYSANTHEMUM SOURCE D'OR—A SUPERB OLD VARIETY.

SIR,—In looking through some old copies of THE GARDEN of January, 1926, I came across some interesting references to this splendid decorative chrysanthemum, and I shou d like to add a word of praise to this old variety along with your other correspondents. It is a well known fact that very many beautiful sorts of chrysanthemums have been lost to us, for the reason that they have been superseded by those having larger blooms—but not always better. One in point is Source d'Or, a decorative variety of the Japanese class. I sometimes wonder if there are many among those who grow chrysanthemums, who made its acquaintance, or any who, like myself, within the second year of it being introduced procured plants. I showed blooms from these plants in the following November and they were much admired because of their—at that time, novel colour! It is best described as a bright orange, shaded gold, fading to pure gold. It is a good doer, growing about 4ft. in height, and retains its foliage well to the bottom. At its best in the early part of November, I have on several occasions had flowers for cutting quite late in the month. It created a mild sensation when it was first exh bited.

Someone endeavoured to prove that the more recent introduction, Jean Pattison, was "just as good," but although it is similar in regard to habit, the colour is more a coppery bronze, and in my judgment, does not bear comparison with Source d'Or. I do not think there is any other chrysanthemum quite like it to-day, notwithstanding the immense number of sorts. To those who have not grown it, I would counsel them to do so, as for cutting, especially seen under artificial light, it is really very charming, grown either on the crown or terminal. I lost it for a time, but at last succeeded in procuring plants. Not every dealer in chrysanthemums stocks it, some, indeed, looking upon it as quite out of date, but I venture to say if it had to make its *debut* in these days, it would be received with open arms. Those who make a specialty in good things, like Source d'Or, and recognise the value of a flower whether ancient or modern, continue to include it in their collections. One such firm, doubtless appreciating its unique colour, and the fact that when once it has been grown it is not lightly set aside, list Source d'Or. It is that of Messrs. Keith Luxford and Co., of Sawbridgeworth. I mention this because I am often appealed to, particularly by those who grew the variety years ago and lost it, as well as by those seeing it in flower for the first time, as to where it can be obtained. I would like to add that I have had blooms of Source d'Or in good condition for four or five weeks.—W. F.

THE "ROGUING" OF SEED POTATOES

THE grower who wishes to keep his potatoes as pure as possible and at the same time is anxious to have an early crop, should lose no time in examining the tubers, which are now in the shallow boxes or trays placed in the light for early sprouting.

When the potatoes are sprouting, particular attention should be paid to the colour of the sprouts and the colour and shape of the tubers, so that they can be "rogued" before planting. This "roguing" in the seed boxes is a most important operation and more especially when immune varieties have to be planted in scheduled gardens and allotments. The grower should also take reasonable care to see that each variety purchased is pure and certified stock, this will save much valuable time and trouble afterwards, for, if the potatoes are not pure, what guarantee has he that his crop will be free from wart disease.

The advantage in boxing seed is now an established fact and it must be admitted that "roguing" seed can be best carried out when the tubers are placed in single layers with the rose end uppermost and examined from time to time.

The colour of potato sprouts varies from faint pink to dark reddish pink and from faint blue to dark purple and it is interesting to note that a variety with pink on the skin of the tuber, even although only around the eyes, can be seen on the sprout stem and sometimes in the flower. A blue coloured sprout will show blue or purple on the stem and the colour will sometimes appear in the flower.

To "rogue" seed potatoes successfully, first find out the colour of the sprout of the particular variety, so that those which are slightly different in colour and shape may be removed.

It is frequently found that Great Scot is mixed with Arran Chief. The tuber alone does not help to separate them, as they are both round, but if sprouted, Great Scot develops a faint pink sprout, while Arran Chief has a blue purple sprout.

Although every precaution is taken to keep seed pure, "roguing" during the season of growth must also be carried out.

Meantime what every grower should aim at is the growing of pure and healthy stocks. If, for example, the above mentioned varieties were planted in wart disease infested soil, how is he to obtain a good, clean crop, when Arran Chief is so susceptible to the disease.

Below is given a tabulated list of immune and susceptible varieties of potatoes, together with colour and shape of tuber and colour of sprout as a guide to those who wish to "rogue" their stock in the seed boxes with a view to keeping them pure and healthy.

FIRST EARLY VARIETIES.

Variety.	*Immunity.*	*Colour and Shape.*	*Colour of Sprout.*
Arran Rose	Immune	Rose pink, round	Rose pink.
Di Vernon	do.	Purple, kidney	Blue purple.
Duke of York	Non-immune	White, kidney	Faint pink.
Early Pink Champion	Immune	Pink, round	Pink.
Epicure	Non-immune	White, round	do.
Harbinger	do.	do.	do.
May Queen	do.	White, kidney	Blue purple.
Ninetyfold	do.	White, round	Pink.
Puritan	do.	do.	Faint pink.
Sharpe's Express	do.	White, kidney	Pink.
Sharpe's Victor	do.	White, oval	Blue.

SECOND EARLY VARIETIES.

Arran Comrade	Immune	White, round	Blue.
Ashleaf Kidney	do.	White, kidney	do.
British Queen	Non-immune	White, oval	Pink.
Catriona	Immune	Purple, kidney	Blue Purple.
Clovullin	do.	White, oval	Pink.
Crusader	do.	White, kidney	do.
Dargill Early	do.	do.	do.
Edzell Blue	do.	Blue, round	Blue.
Great Scot	do.	White, round	Pink.
K. of K.	do.	Pink, kidney	do.
King George V.	do.	White, oval	do.
Nithsdale	do.	White, kidney	Blue.
Snowdrop	do.	do.	Pink.

MAINCROP VARIETIES.

Abundance	Immune	White, oval	Purple.
Arran Consul	do.	do.	Pink.
Arran Victory	do.	Blue, round	Blue purple.
Ben Cruachan	do.	White oval	Blue.
Ben Lomond	do.	do.	do.
Bishop	do.	White, kidney	Pink.
Celt	do.	White, oval	do.
Claymore	do.	White, round	do.
Golden Wonder	do.	Russet, kidney	Blue purple.
Incomer	do.	White, oval	Pink.
Irish Queen	do.	Pink, round	do.
Kerr's Pink	do.	do.	do.
King Edward VII.	Non-immune	Pink, kidney	do.
Lochar	Immune	White, round	do.
Majestic	do.	White, kidney	Faint pink.
Norna	do.	do.	do.
Northern Star	Non-immune	White, round	Pink.
Rector	Immune	Pink, round	Dark pink.
Roderick Dhu	do.	White, round	Pink.
South Esk	do.	do.	Blue purple.
Stirling Castle	Non-immune	do.	Pink.
Tinwald Perfection	Immune	White, oval	do.
Up-to-Date	Non-immune	do.	Red purple.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE mild open weather now with us ushers in the busy season of the amateur gardener, and, provided there is a spell of March breezes which are characteristic of the beginning of spring-time, advantage should be taken of week-end and other opportunities to advance the initial operations associated with the preparation of the soil. In favoured districts a start may be made with the planting and sowing of certain vegetables; but not until the advent of April can that work be described as general in Scottish gardens. At the time of writing, heavy loam and clay land are still wet and cold, and only on the light or sandy soils in the vicinity of the coast towns are the conditions suitable and the risks less hazardous.

On the Ayrshire seaboard a large area has already been planted with an early crop of Epicure potatoes, and it is a common practice in private gardens to plant a potato patch in a sheltered border with a southern aspect. Late frosts sometimes cause damage when growth has advanced above the surface, and as a precautionary measure it is not a bad plan to form the drills at the time of planting and thus provide a deeper covering. As an alternative expedient, straw is used to protect the young foliage. In a normal season the crop is ready for digging by the middle of June.

Another vegetable that lends itself to early planting in the open ground is the shallot. The soil should, first of all, be got into a good tilth by raking, and the bulbs may be planted 4ins. apart in rows in a bed, or as an edging to flank a path in the kitchen garden. Plant the bulbs firmly to a depth that enables the neck or pointed portion to remain on the surface. An occasional dressing of soot is useful in promoting growth and keeping away insect pests.

If an early sowing of peas has not been made in a box under glass, two or three rows of an early dwarf variety may now be sown in the border when the soil is workable. William Hurst, English Wonder, Austin's Record and Marvellous are reliable croppers which solve the problem of staking to the small grower, as they only reach a height of 18ins. The old system of drawing a narrow V-shaped drill with a hoe has now been discarded in favour of a shallow trench 6ins. wide and about 3ins. deep, which gives the seeds plenty of room. If taller growing varieties—such as The Pilot and Gradus, 3ft.—are preferred, the space between the rows may be occupied by lettuce.

Towards the end of March, French Horn Carrot and onions for early summer use may be sown outside; while those growers who experience difficulty in raising parsley in the open ground should make a small sowing in a box and germinate the seed in a frame. The resultant seedlings will transplant readily in May, when the soil is moist.

In the flower garden the planting of hardy perennials and roses should be completed by the end of the month at the latest, as these subjects resent disturbance later in the season. In a previous reference to roses I mentioned that common baking soda had been effective as a cure for mildew in America. As readers may desire to give it a trial, both as a preventive and a cure, during the coming season, they should make a note of the formula, which is as follows: Dissolve 1 oz. to 1½ oz. of bi-carbonate of soda in 1 gallon of boiling water, which, of course, is afterwards cooled before use. Soft soap, added to this in the proportion of 2 oz. to the gallon of mixture, is valuable as a "sticker," as it causes the spray to adhere to the foliage.

Stocks, asters, antirrhinums, and a wide range of bedding subjects, including numerous popular representatives of the half-hardy group of annuals, are well suited for early culture in a frame; while autumn-sown sweet peas, pansies, violas and carnations raised from cuttings may now be fully exposed to air and sunshine, only closing the lights when the weather is wet or frosty.

March is generally recognised in Scotland as the best period for taking cuttings of early-flowering chrysanthemums, and the amateur whose glass accommodation is restricted to a single frame will doubtless find it difficult to provide space for his varied requirements. Cuttings in boxes or pots will root at a kitchen or other room window, and another alternative is to transplant violas and carnations when conditions are favourable and use the vacant space for the chrysanthemum cuttings.

While the circuit of spring flower shows in Scotland is numerically small, it is increasing annually. Paisley Florists', instituted in 1782, has the best record, for the members continue to hold a bulb exhibition every year; while older institutions, like the Royal Caledonian and the Glasgow and West of Scotland, were compelled to discontinue their spring shows for want of support. For a number of years the Glenfield Society, Kilmarnock, has taken the lead in encouraging bulb culture among amateurs, and the annual show has no equal in Scotland in respect of the number of the entries and quality of the blooms. Last year Messrs. Austin and McAslan, with characteristic enterprise, instituted a show in Glasgow which combined the exhibition and competitive sections in a most successful manner; and a further example of the increasing interest that is now being taken in bulbs was reflected in the support extended to the experimental show held at Kilmalcolm recently.

ST. MUNGO.

GREENHOUSE NOTES

Repotting Greenhouse Azaleas.

GREENHOUSE azaleas are extremely useful as well as beautiful, useful, because the plants can be retained in good health for many years, and, if well managed, flowered freely every year. During the summer months they cause no more trouble than that entailed by watering and daily syringing during hot spells of weather. Of course, correct treatment is essential and amateurs, who now possess plants and have not had any previous experience, should duly note the following points. Directly the flowers are faded, carefully remove them without breaking off any young shoots. If a vinery or peach house is available, place the azaleas in it and syringe the foliage with tepid water early every forenoon. The object of the syringing is to induce a free and healthy growth of young shoots and to prevent red spider and thrips spreading on the undersides of the leaves. The new shoots grow and mature from late spring until the middle or end of September. The time for repotting plants that require more rooting space is when the new shoots begin to grow. The ideal compost is one made of very fibrous turf (which has been cut and stacked at least four months), and peat, with the fine portion sifted out, in equal proportions. If peat cannot be obtained, use half-decayed tree leaves. Sufficient coarse sand should be added to make the whole porous and the potting should be carefully done. Pots and crocks must be clean and dry and the new compost well firmed with the aid of a potting stick. When all is ready for the work of repotting to be done, turn out the old balls of soil and carefully remove the crocks. The bottom of the ball of soil is shown at *a*; and after the crocks are removed it looks like the sketch *b*. The crocks are shown at *c*. The drainage and rougher material in the new pot are shown at *d*, the new compost at *e*. The top of the old ball of soil *f*, must not be covered with new soil except where the old is badly worn away. Take great care of the young shoots *g* and *h*. When full maturity of young growth comes—as it should by September—the new flower buds will be formed, too, as shown at *i*, then there will be a good prospect for the next years bloom.—GEO. GARNER.

Present Treatment of Old Greenhouse Pelargoniums.

OLD pelargoniums generally pass through a winter season better than young ones because they are well rooted and the wood is firmer. Having cut away some of the longer shoots of the old plants, be careful not to over-water for a time. When the new shoots begin to grow, a thorough watering will be beneficial, and it is at this stage that the old plant can be taken from the pot, its soil around the roots reduced in bulk and the plant repotted in a smaller pot. As the time passes, the plants should be shifted to larger pots, thus causing vigorous growth without having the plants in larger pots than they were when pruned back. The very best compost for zonal pelargoniums is one made up of fibrous loam two-thirds, sweet leaf-soil one-third, and a 5in. potful of bone-meal to each bushel of the combined parts.—HANTS.

THE FRUIT AND KITCHEN GARDEN

What to Do During the Month.

THE month of March is a very busy month for gardeners. We in the north, who have a few early potatoes sprouted, usually try to get in a few short rows during this month. Provided the weather is good and the ground in good working condition, no harm will result; but, bear in mind, they will need a lot of attention later on. Many ways are tried in the planting of potatoes, but the best way is to open a trench out at one end of the piece of ground and put the sets in the trench. Dig the ground, and every 20ins. make your rows of potatoes. In this way the whole of the piece is made light and in good order for potatoes. Level the bottom of the trench, put a layer of manure in the bottom, plant the sets 15ins. apart, and cover the sets with strawy manure, bracken or anything of a light nature. A row of dwarf early peas sown after every six rows of potatoes may go in now. Do not bury the seed too deeply, and steep the seeds in paraffin or dress with Horticol if mice are numerous. Red lead may be used, but should be used with care. As soon as the seedlings appear, draw a little soil up to them and put short stakes for support and to shelter the potatoes when they come through. Do not be in too big a hurry to earth up the potatoes in care of frost, for we do not get frost every night even in the north. Rather, try to cover them with straw, bracken, or even pea sticks at first, or you will find that in May you have no soil left between the rows to earth up with, and if you cover the tops with soil from the first the tops will be drawn, whereas covering with straw, etc., at night, when there is danger of frost, and uncovering through the day, the tops will remain sturdy.

Shallots will require planting now. All that is necessary is to press the bulbs into the soil in rows a foot apart.

Broad beans can be put in now, dibbling the seed 9ins. apart and about 4ins. deep. Onions can be sown towards the end of the month. A good plan is to mix a little carrot and lettuce seed with your onion seed before sowing. The lettuce can be transplanted along the edge of the path, and saves making a special sowing, and the carrots can remain. Lots of people believe the carrots help to keep off the onion fly, and certainly where I have seen it tried there is less damage by fly to the onions.

Parsnips require a fairly long growing season, and should be sown during the third week in March on land which has not been recently manured. Allow a space of 15ins. between the rows, and thin out early to 4ins. or 5ins. and, later, every other plant. Every one should grow a few leeks, and seed should be sown towards the end of the month, or plants should be secured about the middle of June.

Cabbages, cauliflowers and sprouts will require sowing now, also a pinch of parsley seed. Very little seed of each need be sown, and I am in favour of sowing into boxes of soil instead of making a seed bed in the garden. The boxes can stand on the edge of the path or in a corner, and can be covered over the top with wire netting to keep off the birds. Always make a practice of transplanting all seedling greens, as much better plants are obtained. Keep off your garden as much as possible, as it only makes the ground sad, and worse for the plants, and takes more working during the year to keep it light.—J. P.

Late Pruning of Gooseberries.

IN certain districts, near woods, where birds are numerous, it is an advantage to leave the pruning of gooseberries as late as possible. Some cultivators thin out branches and do not prune at all in the ordinary way, because the birds eat out all buds except those near the tips of the shoots. But, besides the trouble caused by the birds, late pruning does result in late growth and fruiting, thus enabling the tender berries to escape injury by late frosts. Cut off leading shoots to a bud, in each case, that points upwards, so that the next leader will improve the form of the bush or maintain its good shape. The weight of the berries always bears down the branches. Very lightly fork up the soil round and under the bushes and then scatter bone-meal on the soil at the rate of 6 oz. per bush. Lightly rake in the bone-meal afterwards, then all the roots will be benefited.—CHRISTCHURCH.

Current Work with Plants in the Garden Frame.

I LIKE to see, at this time, a garden frame nicely placed on a firmly made hot-bed in an open position, but one sheltered from the north and east winds. The amateur who possesses such a frame is fortunate, because he can bring on so many young plants quite sheltered from the weather. Young onions and leeks raised, perhaps, on the shelf in a warm greenhouse, should be transferred to the frame on the bed now. Hundreds of sturdy lettuce plants can be raised in a small box. The main-crop celery seeds may be sown, too. The atmosphere will be quite suitable for a steady, sturdy growth. Frame cucumbers and the early vegetable marrows should now be raised; plants of the last-named will be about 8ins. high and possess three large, rough leaves in addition to the three or four smaller ones at the top, by planting-out time—early in June. The frame cucumber plants will be ready for planting in the frame itself permanently in due course. In cold districts and where clayey, retentive soils obtain, it is a good plan to sow seeds of runner beans in a box 6ins. to 7ins. deep, filled with loam and leaf-soil in equal proportions. The seeds should be sown 4ins. apart and 2ins. deep. I always raise my early runner bean plants in this way and, being carefully hardened to outdoor weather, they are sturdy specimens 9ins. high by the first week in June, when they are planted in the trenches prepared for them. If staked forthwith and a few branches are also placed to both sides of the row, a check does not occur and the first flowers are soon expanded.

In the case of all seedlings raised in a garden frame, duly ventilated, there is not any weakening of them, as so often occurs when they are raised on greenhouse shelves. Besides being of great use in the case of vegetable seedlings, the garden frame is equally useful at the same time for bringing forward pans, pots and boxes of half-hardy open-air and greenhouse annuals. The general compost to endeavour to procure or make up is one, for vegetables, of sweet loam two-thirds, leaf-soil one-third, and a 6in. potful of old mortar rubble to each bushel. Where it is advisable to shade certain seedlings, shade several squares of glass immediately over them and not the whole of the glass light, or other kinds would be weakened —GEO. GARNER.

Sprays and Their Uses: Lead Arsenate.

ARSENATE OF LEAD depends for its insecticidal properties on the fact that it is a stomach poison and is used against biting insects, such as caterpillars, beetles and sawfly larvæ. It does not affect sucking insects.

The substance is a heavy white powder nearly insoluble in water. It is fairly stable and can be stored with safety.

Owing to its insolubility in water and its weight, when mixed with water it tends to settle rapidly and it is therefore necessary for spraying purposes to obtain it in a form which will give a fine suspension in water in order to insure an even distribution over the article sprayed.

Until recently the best form to use was that sold as arsenate paste or cream, which, when shaken up with water, gave a fairly fine suspension, but on evaporation of the water the suspended particles tended to coagulate, forming lumps on the leaves with consequent irregular distribution.

Latterly, manufacturers have placed on the market a very fine arsenate powder, which gives a very fine suspension in water and does not leave lumps on the evaporation of the water. This form is far superior to the paste or cream and is much easier to handle, and also leaves a fine covering of arsenate particles over the surface sprayed.

The quantity of lead arsenate required depends on the material used and it is advisable to consult the manufacturers directions. Usually two or three pounds of lead arsenate in the form of powder, or four to six pounds in the form of paste to one hundred gallons of water is sufficient.

Mix the required quantity of arsenate required in a pail with a small quantity of water to form a cream, making sure that there are no lumps left. Add this to the container, holding the required quantity of water for the amount of powder used, and stir thoroughly. Stir before spraying.

The spray should be applied from a fine nozzle, with sufficient force to form a fine mist. Precaution should be taken not to overwet the trees, otherwise dripping will ensue and a good deal of the spray material be lost.

Arsenate of lead is very poisonous both to human beings and animals, so every precaution must be taken. Trees, under which vegetables or small fruits are growing should not be sprayed and poultry and stock should not be allowed to feed under trees that have been sprayed.

The following table gives a list of pests which may be wholly or partially controlled by spraying with lead arsenate. It is advisable to spray as soon as the pest is noticed and to follow up with another spraying a week or ten days later. For codlin moth the trees should be sprayed just after the blossoms have fallen, *i.e.*, the calyx stage.

Pest.	*Stage.*	*Time of Application.*
Brown Tail Moth.	Caterpillar	Middle to end of April.
Codlin Moth	,,	Directly the petals have fallen.

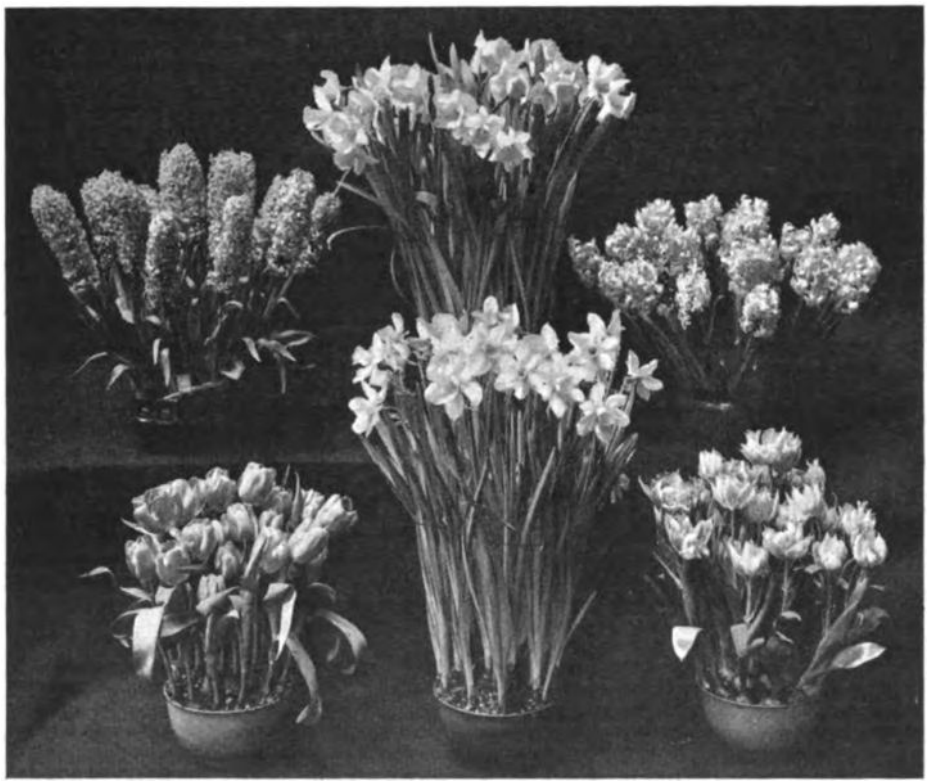
A SPRING SHOW AT GLASGOW

THE amateur element was strongly represented at the flower show held recently in the McLellan Galleries, Glasgow. The event, which was instituted a year ago by Messrs. Austin and McAslan, created widespread interest throughout horticultural circles in Scotland and the support given by competitors, exhibitors and the general public has justified the enterprising venture and ensured its success.

In the sixty-one competitive classes, the outstanding feature was the prize-winning record of Mr. Hector Fraser, Paisley, who excelled in no fewer than thirteen classes and in addition secured the special prize for the best amateur exhibit in the show with six bowls which revealed a very high standard of culture. The bowl of miniature hyacinths contained twenty-five flower spikes of the variety Marconi, while another bowl had seventeen large trusses of the single crimson sort, La Victoire, all uniform in size and at the same stage of development. Mr. John Russell, Newtoun-Mearns, was next in the prize list with seventeen honours, of which seven were firsts, to his credit, while Mr. Claud Jenkins occupied third place with eight first prizes. Competition was keenest in the classes for pot hyacinths and in the class for one pot Narcissus King Alfred. Taken all over the blooms reached a high average of quality and showed a marked advance on that of 1926.

The best exhibit in the gardeners' section consisted of three fine pots of cyclamen staged by Mr. William McCarrell, Deanston House, Doune, who also exhibited an attractive group of cyclamen seedlings.

The decorative side of the show surpassed anything previously seen in Glasgow and was contributed by Mr. Robert Paterson, Stamperland (orchids), Sir A. B. Cayzer, Gartmore (carnations), Mr. H. Erskine Gordon, Aitkenhead, Cathcart (cyclamen), Lady Muir, Deanston (primulas, begonias and cyclamen), Mrs. Stewart Paton, Holmglen, Caronunnock (daffodils) and Lieutenant-Colonel Norman Kennedy, Downholm, Ayr (primulas); while the firm excelled all previous efforts in their examples of terraced and rock gardens, bedding schemes and groupings of pot plants.



THE FIRST PRIZE EXHIBIT OF BULBS IN BOWLS SHOWN BY AN AMATEUR.
The bulbs are particularly well grown, and the varieties are: Top row—Hyacinth La Victoire, Narcissus Van Waveren's Giant, Hyacinth Marconi. Bottom row—Single Tulip Proserpine, Narcissus Sir Watkin and Double Tulip Azalea.

THE GARDENS AT OLYMPIA

THERE is certainly diversity as well as interest in the gardens which are laid out at Olympia in connection with the Ideal Home Exhibition. The exhibitors, despite the many drawbacks, have all attempted to show what may be accomplished in gardening in a small space, and although the tendency seems to be to keep to the stereotyped designs demonstrated in previous years, the gardens in themselves stand as one of the prominent educational features of the exhibition and should prove of great assistance to those to whom garden design and planting prove problems of some little difficulty. It is, perhaps, unfortunate that no nurseryman strikes a novel note in his exhibit—one, for example, where the design and planting would be in keeping with a back garden space such as is so typical of many of our suburban houses. Such a design would be certain to interest thousands of visitors to the exhibition if details of planting and approximate cost were given for the visitors' information. The Gardening Section, like the other sections in the exhibition, must demonstrate progress from year to year, and the method of progress is to cater for the present demand for a pleasant and attractive type of suburban garden.

This year, the general style of the exhibits is on freer and more flowing lines and, from a general appearance point of view, the Annexe provides many beautiful garden pictures. A few of the gardens are particularly good, both in design and planting, and show a finish which is commendable, since such is often wanting in garden exhibits. In these few cases, the central feature or *motif* of the garden is self-evident, but in others it is entirely wanting, due to bad design and planting. Such gardens are unworthy of the exhibition, and it is to be hoped that improvement will be registered in this direction on future occasions. On the whole, more care has been shown—care in planting and in avoiding a note of incongruity, both of which have been lacking in the past. There is still room for improvement in a few cases, and, as it is a point of some importance, it should receive immediate attention from all exhibitors. If a garden is to be exhibited, then let it be done well.

The most attractive garden from an appearance viewpoint is that laid out by Messrs. Carter and Co. in the Italian style. In a way it is a trifle too ornate for the exhibition; but for the person who has means, it indicates how a small and limited area can be transformed into a corner of beauty. The central feature is a quietly designed marble fountain standing on a raised mound and surrounded by tall cypresses, while in the centre are fountains and in the foreground neat beds of pink and blue cinerarias, with beds of Dielytra spectabilis. Daffodils and early-flowering shrubs supply a touch of spring colour, certainly, but are a little out of keeping with the style of the garden. Still, the effect is a very fine display of colour and bloom which undoubtedly makes the exhibit most attractive.

Close by is a garden devoted to perpetual-flowering carnations, planted and designed by Messrs. Allwood Brothers, in which is to be seen a wide selection of the best varieties both of the perpetual-flowering kinds and the hardy Dianthus Allwoodii. Another specialised garden is that arranged by Messrs. Reamsbottom, with their St. Brigid and Caen anemones, with bold patches of the brilliant A. fulgens. The beds and borders make a bright splash of colour, and the exhibit should go a long way in popularising these flowers, which, from the amateur's point of view, are excellent in the small garden for providing an effective floral display. Still another special garden is the small and neat terrace garden planted with violets and Primula Wanda, by Mr. Baldwin Pinney.

In Messrs. Cheal's formal garden full use has been made of forced shrubs in great variety. Japanese cherries, standards of wistaria, brooms, laburnums, magnolias—all are there and make a bright and colourful display along with many other subjects. Mr. George Whitelegg, in his circular formal garden, has laid out a particularly fine collection of varieties of azaleas of the mollis and sinensis strains, showing many of the modern varieties, such as Anthony Koster and J. C. Van Thol, illustrating their use and beauty in the small garden. In addition there are a number of fine specimen shrubs of Magnolias Soulangeana and conspicua, of Daphne Mezereum and Viburnum Carlesii which indicate to the amateur that, with a judicious selection he may have a fine show of bloom during the early spring months in his garden.

The Country Service Association have constructed a rock and water garden which is simple and natural. Mr. Herbert Brook has reproduced a piece of Westmorland fellside. Here, too, weatherworn stone is used, and in the crevices between the stones and in sheltered corners, can be seen a number of choice rock plants.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2886 Saturday, March 26th, 1927 Price TWOPENCE

DELPHINIUM KELWAY'S DUSKY MONARCH.

THE TOUCH OF SPRING is upon the Garden, NOW IS THE TIME TO PLANT

KELWAY'S DELPHINIUMS

The Ideal Hardy Plant :: for Every Garden ::

THE magnificent Delphinium or Perennial Larkspur is one of the several hardy perennials which *Kelways* have brought to a high degree of beauty. It was the firm of *Kelway* which first improved the varieties and gave the plant its leading position in the flower garden. The many-flowered spikes make a striking display wherever they are grown. No garden plan and no colour scheme can be looked upon as complete without Kelway's *lovely blue Delphiniums.*

They are at prices to suit every purse, for example:

"Collection B," good varieties to name, **21**- per dozen, **150**- per 100.

"Collection D," a wonderful selection, **40**/- per dozen, **300**/- per 100.

"Collection F," the cream of the varieties, **70**- per dozen.

or a descriptive priced catalogue will be send on demand.

"Here were new types, new habits of thought, new ideas, new reactions, new morals, new ways of living."—*H. G. Wells on the present age.*

THE GARDEN

VOL. XCI.—No. 2886. MARCH 26, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Some Bulbs and Tubers for Spring Planting.

SPRINGTIME is flower time for the bulb world, but it should not be forgotten that there are several species which will keep our gardens gay when the flush of summer flowers is past and gone, and carry on until the perennial asters and chrysanthemums bring their wealth of autumn colour.

Among this group the chief honours must, of course, be accorded to lilies and gladioli, but there are, in addition, several other species which should find a place in every sunny garden.

Ixias and their first cousins, sparaxis, may be obtained in a wide range of colours and thrive in any ordinary soil, but should always be accorded the sunniest possible situation. They are usually supplied as "mixed," but where colour schemes are called for, some of the best varieties are H. crateroides major, scarlet; Mozart, bright yellow; Wonder, a good double rose; and viridiflora, a most interesting variety with bright green flowers; Sparaxis Angelique, lemon with orange centre; and S. Fire King, scarlet with yellow centre. They should now be planted in groups about 3ins. deep and as far apart. They make excellent subjects for pots. Five or six bulbs should be set in a 5in. pot and plunged in a cold frame, giving all air possible during mild weather.

Anemones, too, should not be forgotten. The wide-petalled, richly-hued single de Caen type prove very effective in beds and borders, as does the brilliantly-coloured Anemone fulgens, especially against a background of dark evergreens. A pleasing variant of the Caen is the cushion-centred type, with a full centre of narrow florets and a single row of wide guard petals, of which Sutton's Blue Gown is an excellent example. Many people prefer the St. Brigid type, which is a double or semi-double flower, composed entirely of narrow florets and embraces every possible hue. The secret of successful anemone culture is (1) that the ground should be rich and reasonably well drained, and (2) (most important of all), that the roots should be planted not more than 2ins. deep *and the soil made so firm around them that it will not carry any impress if it is trodden upon.* As a fact, it should be trodden or rolled until it is consolidated to the hardness of a garden path. If anemone roots are examined the little hairy crowns are not difficult to discover; these, of course, represent the top and should face the light. Placed in this position the flattish tuberous fingers spread out more or less horizontally. It does not dig deeply into the soil like a dahlia tuber and if it is planted deeply or in loose soil, where the roots are continually moist and cool, they will quickly decay.

The Royal Horticultural Society's Amateur Flower Show.

THE Amateur Show held under the auspices of the Royal Horticultural Society, is to be held at the Society's Hall, Vincent Square, Westminster, S.W.1, on Tuesday, June 28th next, and it is to be hoped that all amateur gardeners will make a note of the date and will endeavour to support the show by staging exhibits, so as to make it the success it ought to be. There seems little doubt that the show will become a permanent feature in the list of the Society's activities, if the continued and unfailing support of the thousands of amateur gardeners is forthcoming. As yet it is only in its infancy—this is the third year—but judging by the improvement which was registered last year in comparison with the inaugural exhibition, the show should prove more successful every year, as more experience is gained by the arrangements committee and more confidence by the various exhibitors. Many amateurs hesitate to exhibit at Vincent Square because of the high standing of the ordinary fortnightly shows at the Hall, but that should not be so. Experience in exhibiting only comes by continued effort and a beginning must be made at one time or another. As with everything else, one learns by mistakes and there is, therefore, no reason why, in time, an amateur's exhibition should not be as attractive and as skilfully arranged as that set up by our trade firms.

It is to be hoped that this year some effort will be made by those in charge of the show to arrange the exhibits better than on the last occasion. There is no reason why some corners of the hall should be crowded, while others are bare. If material is lacking, then let the exhibits which are present have sufficient space in which to be shown off to advantage. If this show is to become a regular feature of the Society's work, then it seems desirable that something in the way of educational propaganda should be done to instruct and help the amateur in the wiles of show exhibiting. We feel sure that such instruction would be appreciated by a great body of amateurs, and, at the same time, it would indicate that the Society is out to assist the amateur gardener, a criticism which is often levelled at the Society as a whole. There is no lack of material, either in plants, gardeners, or enthusiasm, and it should be the aim of the Society to build up the greatest and finest amateur flower show in the world and so live up to our traditions as the premier gardening nation.

The schedule of arrangements for the show, which has just reached us, is divided into three main divisions. (A) Devoted to all amateurs; (B) Only open to those amateurs who do not regularly employ more paid assistants than one gardener and one boy; and (C) Only open to those amateurs who employ no gardener. It will be seen, therefore, that the schedule embraces all classes and gives each exhibitor a fair chance in competition with his neighbour who is similarly situated. The classes remain much the same as last year, except that the classes for roses have been increased from seven to sixteen—an excellent improvement, as there is no more popular flower among amateurs than the rose. In the open division also, classes have been added, among others, for vases of sprays of hardy shrubs, and pots or pans of alpine plants, a bowl of water lilies, a species of rhododendron, one hanging basket, a new plant species introduced to cultivation since 1920, and a new plant of garden origin raised since 1920.

As in the past, substantial prizes are offered, and also a cup for award to the most successful exhibitor in each division. The Society is definitely out to make the show a success and we urge every amateur, whether he be a Fellow of the Society or not, to support the show and make it one of the most important in the gardener's year.

This Week's Work

Prepare beds for planting gladioli.

Prune hybrid perpetual and hybrid tea roses.

Spray fruit trees with lead arsenate. Spray just before the flower buds break.

Finish planting shrubs and herbaceous perennials.

Fork over the herbaceous border and give it a light dressing of short manure.

Hoe all beds containing bulbs, wallflowers, etc.

Sow hardy annuals outside in beds of prepared soil, and sow vegetables of all kinds in the kitchen garden.

Top-dress lawns with artificial fertilisers and sifted compost.

Thin out seedling annuals now in boxes.

Digitized by Google

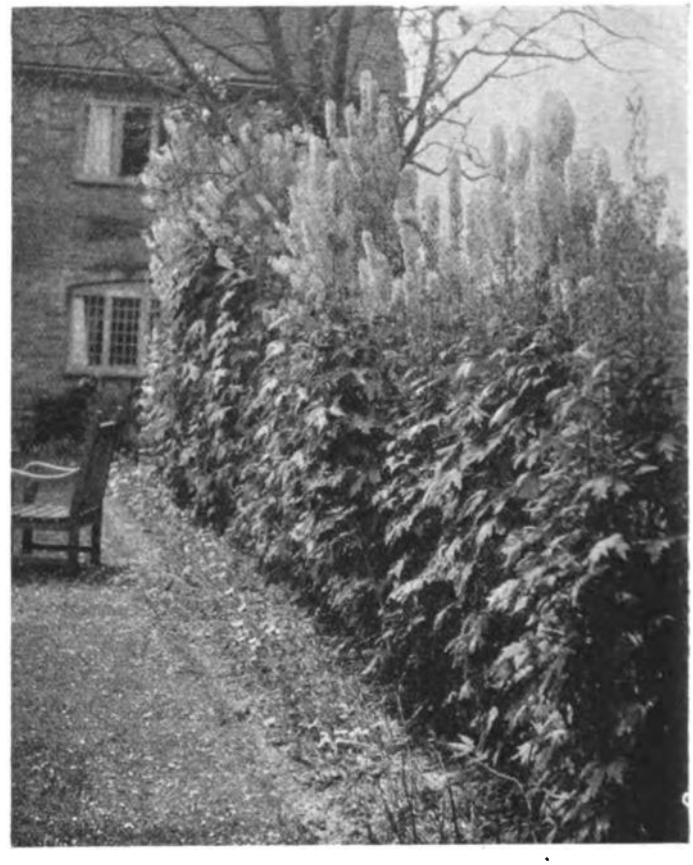
DELPHINIUMS FOR SPRING PLANTING

EXPERIENCE has shown that the best time to divide old delphiniums or to plant new ones is in the spring, preferably in March; but the work can be carried out quite well as late as mid-April or even the end of that month, provided care is taken not to injure the young shoots which by that time will have attained a height of several inches, and that ample supplies of water are given if the weather is at all on the dry side. Delphiniums are anything but exacting as to soil so long as it is not heavy wet clay, but what pleases them best is a rich but light loam, thoroughly well worked and moderately manured; and they like as much sunshine as possible. A light mulch of strawy stable manure in June will be of advantage to them. Slugs, which gnaw off the shoots directly they show above ground, are the worst enemies delphiniums have to contend with, and a vigorous and relentless campaign must be carried on against them. The plan adopted by a leading firm of growers is to remove some of the soil round the collar of each plant and to fill up the hollow so formed with sharp cinders—fine ashes are useless—which, however, are not allowed to touch the stem. A correspondent writing recently to THE GARDEN states that he has had good results from encircling the plants with inch-wide strips of felt soaked in petrol; a ring of Sanitas powder round each is certainly a deterrent; but the easiest, least expensive and probably the most efficacious plan is to water the surrounding ground with a solution of alum—1 oz. to the gallon of water.

In selecting delphiniums there are certain points to be taken into consideration besides that of the depth of one's purse. If wanted for the back of a wide border, those that reach a height of 5ft. or 6ft. should be chosen; if to be massed, they should be graduated as far as possible; while if intended for a narrow border in a small garden, delphiniums of the belladonna class, such as Lamartine, Fanny Stormonth, Muses sacrum and Persimmon, which do not grow more than 3½ft. to 4ft. high, are most suitable. Plants in a variety of shades of colour should be obtained and special care should be taken to lighten the dark purple blues, which are rather heavy in effect if massed by themselves, by a judicious admixture of clear sky blues, of what may be described as opalescent lavenders, such as Statuaire Rude and Kelway's Ladye Faire, and of soft blue mauves of which Horace Vernet may be taken as a good example.

In these notes it is proposed to give a short list of some of the best delphiniums for present planting, including both new and old varieties. Of the former the Wrexham hybrids introduced by Messrs. Hewitt of Solihull are certainly among the most attractive by reason of their immensely long spikes having the graceful taper of the older (and in most ways greatly inferior) type of delphiniums, instead of the blunt, rather clumsy looking heads of the majority of modern varieties. The Wrexham hybrids are beautiful in line, and their florets are not over closely massed as is so often the case, but are set sufficiently far apart to allow their fine shape and colouring to be fully appreciated. The most striking of these hybrids, Advancement, will not be put on the market until the autumn; but among those now offered are Integrity, blue purple flushed cobalt; Rose Marie, pansy purple with a dark eye; Ruffled Beauty, violet shaded mauve; Monarch of Wales, bright blue with reddish mauve inner petals (this has an extra long and very finely tapered spike, and was illustrated in colour on the cover of THE GARDEN in September, 1926); and The Bishop, which resembles the popular Rev. E. Lascelles, but is richer in colour and has a larger white eye. All the foregoing reach a height of 5ft. to 6ft.; but the pretty, rosy mauve Joy-bells, although of the same strain, is only 4ft. to 4½ft. high. The Sylph, another of the Wrexham hybrids, is a welcome addition to the very limited number of white delphiniums; it grows about 4ft. tall and is double.

An attractive new variety of dwarf habit from the Langport nurseries is York Gala, which is a beautiful shade of sky blue slightly flushed with mauve. Other novelties introduced by Messrs. Kelway and Son are: Ultra-violet Rays—its name indicates its colour; Locarno, brilliant blue shaded violet, with very long florets on unusually long stalks (this variety would group well with Jewel of the West, milky lavender, and Kelway's Pageant, sky blue flecked with pink); Wedding Bells, a harmony of sky blue and pinkish mauve; and Josephine Kelway, a single version of an older favourite, the clear blue semi-double Mrs. James Kelway. As has been said above, there are but few pure white delphiniums in existence, but Messrs. Kelway and Son have a particularly good creamy white in Beauty of Langport and a deeper cream in Mrs. Christie Miller. The last-named is of dwarf habit and, combined with the Persimmon variety, Kelway's Blue would fill a large bed charmingly, especially if the latter were edged with a broad band of a blue annual such as Phacelia campanularia, Nemophila insignis or Nemesia Blue Gem.



DELPHINIUMS LOOK WELL BY THEMSELVES IN A BORDER NEAR THE HOUSE.

OR THEY APPEAR EQUALLY BEAUTIFUL WHEN PLANTED IN CLUMPS IN THE MIXED HERBACEOUS BORDER.

Digitized by Google

Although not among the latest, The Shah is certainly one of the most desirable of Messrs. Blackmore and Langdon's introductions, by reason of its uncommon and attractive colour, a warm shade of rose lavender; it has a dark eye and is semi-double. Newer varieties from the same source are Countess Cowley, light blue and mauve; R. A. Pilkington, deep violet edged dark blue with a brown eye; Queen Mauve; J. Pitts, sky blue flushed rose; Millicent Blackmore, blue and mauve; and Blue Boy. The last is a very beautiful delphinium with a long, finely tapering spike; its colour is a deep clear blue and it is a giant in stature.

Of older kinds, the following are a few among the many that have proved their worth: The Alake, purplish blue; Edward Bromet, royal blue with a white eye, somewhat similar to the Rev. E. Lascelles; King Bladud, cobalt blue, double; King of Delphiniums, gentian blue shaded plum (this should be obtained from a grower of repute, as there are some poor strains in the market); Lavanda, rosy lavender; Sir Douglas Haig, purple blue; Smoke of War, a curious reddish purple tinged deep violet (should be grown with delphiniums of lighter and brighter shades); Silver Buckle, pretty clear sky blue; Monarch of All, violet purple, brown eye; Queen of Bath, azure blue, dwarf; Blue Bird, deep blue (this has a very graceful spike); Porthos, blue and rosy mauve, semi-double; and Duke of Connaught, cobalt blue flushed violet. R. E. HEAD.

GLADIOLI AND THEIR USE IN THE GARDEN

Suggested Arrangements which will Make Your Garden Bright in the Late Summer and Autumn

THE present-day race of gladioli which have been so popular during recent years, are invaluable in many ways for garden as well as for indoor decoration. With so many varieties to choose from, with their varying time of flowering, it is possible, by planting at different times, to have quite a long display. Where it is desired to have an early display the corms may be placed in pots and started in cold frames, from which they are hardened off and planted out in due course in the sites prepared for them. Where they are required in quantity for indoor decoration they should be grown in a small reserve border in the kitchen garden. There are numerous ways in which gladioli can be used in the garden. With so many beautiful varieties to choose from it is easy to use them in definite colour schemes either alone or, better still, in combination with other plants suitable for the purpose. The large-flowered varieties are most useful for the larger and more imposing arrangements, while the lighter and more graceful primulinus varieties are best suited for more dainty grouping.

Gladioli are very useful for grouping in the mixed border, either in places reserved for them or planted in between early-flowering plants. Peonies, for example, are rather difficult subjects to interplant with late-flowering plants, as their broad leaves give very few plants a chance to develop, and gladioli, with their slender, upright growth, soon push their way up through the foliage without suffering in any way. Of course, one would not grow them in that way for exhibition purposes, but here we are considering their general utility for decorative work in the garden. The large-flowered varieties may also be used effectively for filling vacant spaces in the front of shrubberies, and thus doing much to brighten them when they are out of flower. Not the least of their merits is the fact that they can be planted with almost any class of plants without overgrowing or injuring them in any way.

Their formal habit renders them specially suitable for filling borders or formal sets of beds if they are fairly large in size. Generally speaking, the effect is enhanced if they are under-planted with some suitable subject, which may vary, from a low-growing plant a few inches in height to one attaining a height of 12ins. to 15ins. When dealing with the taller-growing plants for this purpose it is important that they fit. By this I mean that their general outline and shape should harmonise with the gladiolus. This is a detail that is too often overlooked in all sorts of floral arrangements. Antirrhinums in many ways are ideal for this purpose, the intermediate varieties being the right height, while there is a wide range of colours to choose from if one wishes to make definite colour combinations, or, if desired, they may all be safely mixed. The softer pink, rose, buff and terra-cotta shades are very charming used with the more refined primulinus varieties. Where a dwarfer-growing plant is required or preferred for planting with them Phlox Drummondii is very suitable, as there is a wide range of colours, and of all our half-hardy annuals this one has the longest flowering season of any. There are, of course, many annual plants that can be used for this purpose, according to individual taste.

As already indicated, gladioli may be usefully employed for interplanting with the early-flowering herbaceous plants. I have found them specially useful for planting in beds and borders of peonies. They can also be used very effectively along with red hot pokers (kniphofias), but in this case—as some of them at least are likely to be in flower at the same time—the colours must be selected with care. A very effective bed is that fine late-flowering variety War closely under-planted with Rudbeckia speciosa. A very pleasing set of formal beds noted last season was planted with Spanish irises carpeted with blue, white and yellow violas. During the spring the beds were interplanted with mixed varieties of Gladiolus primulinus, the violas afterwards being removed and replaced with mixed varieties of intermediate antirrhinums. Thus, with very simple material and little trouble, a beautiful and prolonged display was secured. One of the most charming periods of the display was when the iris and violas were in full flower and the gladioli just about half-grown, their foliage forming the right setting for the irises, enhancing their effect and giving that elusive air of distinction to the whole scheme which one so often fails to achieve.

ALL LARGE-FLOWERED VARIETIES ARE EMINENTLY SUITABLE FOR BEDDING PURPOSES.

The examples given will serve to indicate the many ways in which this charming class of plants may be grown. Few gardens are so small that room cannot be found for them, for, as indicated, they can readily be interplanted among so many other plants. If no other space is available, I should not hesitate to plant them among roses, as they do not interfere with one another in any way. Much of this may not be in accord with the exhibitor or large grower; but in this short note I do not have them in mind so much as the individual with a small garden who in the past may have been afraid to attempt the cultivation of gladioli. Their cultural requirements are few and not exacting. That, however, at this time is outside my province, as that phase was fully dealt with in these pages last week.

Digitized by Google

Although it is not the proper season, I wish to refer to a class of gladioli the cultivation of which is, I am afraid, very much neglected by garden owners generally. Here I refer to the so-called nanus and ramosus groups, which are so useful for pot culture, and includes such beautiful varieties as Blushing Bride, Daliticatissima, Ackermanni, Fire King, Peach Blossom and many other fine varieties. G. Colvillei and its well known white form are also used in the same way for pot work and forcing. Although the nanus and ramosus varieties are grown by marketmen for the cut-flower trade, they in gardens generally are too much neglected, which is surprising considering they can be grown in cold frames and later on, when they require more head-room, in a cold greenhouse; while, if so desired, many of the varieties will stand moderate forcing.

They grow freely in any good potting compost, and should be potted up during October, as they are free-rooting subjects and enjoy plenty of water during their growing season. They should be given fairly large pots, allowing six to eight corms, according to size, to a 6in. or 7in. pot. If required in large quantities, they may be grown in boxes or planted out in frames. In the south and west at least they succeed outdoors in warm, sheltered borders. In such situations they may be planted during the autumn, or planting may be deferred until early in the new year. Garden owners with a small unheated greenhouse should certainly consider growing this section of gladiolus, as they would be a useful addition to the plants commonly grown in such structures.

The gladiolus cult has, during recent years attained immense popularity, not only at home, but on the Continent and America. In spite of the many fine present-day varieties, there is no reason to suppose that any finality has been reached in the production of new varieties, or even of new hybrids, for there are still many beautiful South African species, some of which may have great possibilities for hybridising, especially is this so when one considers the many beautiful varieties that have resulted from the use of G. primulinus and it is not impossible that in the future we may have other sections of gladiolus to grace our gardens. J. C.

HYBRID RHODODENDRONS WORTH GROWING

Hybrid rhododendrons are among the most popular of shrubs by reason of their easy culture in any soil which is lime free and their gorgeous flowering display in April and May. One or two of these splendid hybrids should be planted next month to add brilliance and colour to the garden next spring. A selection can be made from the following list where good all-round garden varieties are mentioned and described.

THERE are few shrubs that have been hybridised more than the rhododendron. The reason for the enormous number of hybrids that now exist is fairly obvious; the hybrid is more amenable to ordinary garden treatment than is the species. Year after year the number of gardeners who are becoming interested in the cultivation of species increases, but, with the exception of the dwarfs, which are suitable for the rock garden, few species will succeed so well as hybrids in the average garden. Considering that most rhododendrons in their wild state prefer to grow either in more or less shade or in countries where the summers are moist and misty, it is surprising that so many hybrids will flourish in the open, but, unfortunately, it is just that supposition of hardiness and lack of objection to strong sunshine that makes gardeners careless over the cultivation of even the hardiest hybrid. In fact, it is safe to assume that 80 per cent. of all rhododendrons in average gardens are not as good plants as they might be.

In many cases gardeners are advised to grow their rhododendrons in peat and to give them other specialised treatment; this is not necessary. They will grow and flourish in any soil that is lime-free, so long as the drainage is efficient. It is natural that as they are plants that prefer a certain amount of shade, they will succeed best in thin woodland, but that is a condition that many gardeners are unable to give them. With a few exceptions most hybrids now in commerce will do admirably in almost full sun, so long as a few simple precautions are taken and assistance is given. As was stated above, good drainage is essential; heavy soils must be thoroughly broken up and lightened with the addition of humus, either in the form of leaf-mould or of peat moss litter, and with sharp sand or even gravel. Light soils may also want additional humus, for it must be remembered that rhododendrons naturally live in woodland, where much of the soil is made up of decaying vegetable matter.

Planting too deeply is a fault that is frequently practised with all shrubs, but it is a grave error in the case of rhododendrons, which are surface rooters with masses of fibrous roots. A rhododendron that is planted too deeply will never make a fine plant. The soil should never be higher than the collar that divides the stem and the root system. I cannot impress too strongly upon beginners the necessity for shallow planting; it is no exaggeration to say that most of the weak and sickly looking plants so often seen are the result of planting too deep in the soil.

Another point that beginners should note is the

A USEFUL LIST OF HYBRID RHODODENDRONS.

Name.	*Flowering.*	*Colour.*	*Notes.*
ALICE	May	Rose-pink	Somewhat similar to Pink Pearl. An admirable plant in full sun. Large trusses.
ASCOT BRILLIANT	April	Red-crimson	An excellent red for the ordinary garden.
BAGSHOT RUBY	May	Ruby-red	Quite good as a standard, and a very floriferous hybrid.
B. DE BRUIN	May-June	Bright red	Rather later than the two previous reds and paler in colour.
CAUCASICUM ALBUM (*b*)	April	White	It is doubtful if this is a hybrid, but it is absolutely hardy and a fine plant. Does not grow very tall.
CHRISTMAS CHEER	February	Pale rose	The earliest hybrid to flower; small trusses, but will stand a good deal of frost without cutting; should not be planted as specimens.
CORONA	May	Deep pink, getting paler.	A very useful hybrid with large trusses.
CUNNINGHAM'S SULPHUR.	May	Pale yellow	A very old hybrid that is again becoming popular; very floriferous and at a young stage, but a slow grower. Should not be planted as specimens.
CYNTHIA (*b*)	Early May	Deep pink	Good truss and large foliage.
DONCASTER	May-June	Bright scarlet	A very fine colour, does not grow to a large plant.
DUCHESS OF PORTLAND.	April	White	One of the best whites.
ESSEX SCARLET (*a*)	June-July	Bright red	One of the latest of the reds to flower. A vigorous grower.
GEORGE HARDY	May	White	Large trusses and dark foliage, a very good hybrid.
GOMER WATERER	Late May	White with mauve tinge.	A good hybrid in all positions.
IVORY'S SCARLET (*b*) (*a*)	May	Scarlet	The best scarlet. Grows to be a large plant.
HANDSWORTH EARLY WHITE.	April	White	A good useful rhododendron
LADY CLEMENTINA MITFORD (*a*).	May	Peach with darker edge.	An uncommon colour.
LODER'S WHITE (*a*) (*b*)	May	White	The most aristocratic hybrid for the ordinary garden, with magnificent trusses that are not so tight as in many hybrids; absolutely hardy.
MRS. E. C. STIRLING	May	White	Exceedingly floriferous.
MOTHER OF PEARL	May	Soft pearly-white	A sport from Pink Pearl with a delicate colour.
PINK PEARL	May	Pink	Probably the best known hybrid; an admirable plant, very floriferous, with large trusses.
ROYAL PURPLE	May	Vinous-purple	An uncommon dark colour.

Digitized by Google

importance of planting rhododendrons in a depression, rather than in a raised bed. Although drainage must be efficient, they are plants that abhor drought. Water will run off a raised bed, whereas it will collect in a depression and keep the soil cool and moist. A depression is also useful for the annual spring mulch of leaf-mould, old leaves, or peat-moss-litter, which assists them enormously in their growth and also helps to conserve moisture. If you are in any doubt as to the efficacy of this suggestion, test it with two rhododendrons by planting one in soil that is raised a little above the level of the surrounding ground, and the other in a little depression with a generous mulch added. You will find that the plant in the depression will have leaves of larger size and will make double the growth of the plant in the raised bed. The mulch and the depression will mean that less watering is necessary unless in extreme drought, but when water has to be applied, let it be thorough. A copious watering once a week will do the plant infinitely more good than a little added each day. Watering should always be done in the evening when the sun is off the plant.

Most hybrid rhododendrons can either be grouped in beds, when in course of time they will grow into one another, or be planted as specimen plants. Many of the older varieties can now be purchased as standards by gardeners who like a rather formalised plant on a long stem, but on the whole, ordinary bushes are more suitable, except in special positions. Care should be taken in planting in groups those rhododendrons whose colour is composed of some form of red, whether the shade be rose, pink, salmon, scarlet or crimson. There are few flowers in which such a profusion of red tones exist and, unfortunately, many of these reds have an admixture of blue. It is well known that blue-reds are the most difficult colours to place in the garden, for they clash in almost every combination. Unfortunately, the human eye is unable to take in the exact differences between various shades of red unless they are close enough actually to compare one with another, so plants for mixed groups or beds of

BAGSHOT RUBY BLOOMS WELL AND MAKES AN EXCELLENT STANDARD PLANT FOR A BED ON A LAWN.

LODER'S WHITE, THE FINEST WHITE HYBRID FOR EVERY GARDEN.

pinks, roses and other reds should be arranged, with great care. It is usually a good plan to confine one red shade only in a bed and if a mixture of colours is thought necessary, alternate the red tones with white. If varieties of red shades are required, these can be tested out and colours that clash can be transplanted to other situations, but if possible, rhododendrons should be seen in flower and actual comparison made before red shades are selected for grouping together. It may be imagined that this question of red shades is over emphasised, but the beginner will find that clashing tones are a real danger in planting rhododendrons and a little extra care is well worth the trouble. Reds with an admixture of blue are always difficult to place.

Thus we can formulate certain rules for hybrid rhododendrons:

1.—They prefer a certain amount of shade, but in most cases this is not a necessity.

2.—They like a soil that is not too heavy and has always a certain amount of humus incorporated with it. The soil must be lime-free.

3.—They should be planted at two seasons of the year; October-November and March-April. They have no violent objection to being moved at any time, for they are easy plants to transplant, but these two seasons are the best.

4.—They must not be planted too deeply, and it is better if they are planted in a slight depression.

5.—An annual mulch is of the greatest assistance.

Hybrid rhododendrons can only be increased by means of cuttings, grafts or layers, for seed of hybrids never comes true to type. Layering is probably the easiest method for amateurs, but, unfortunately, some of the hybrids are too stiff in growth to allow the necessary bend on the branches. Grafting should only be resorted to if standards are required, for ponticum stock is so vigorous that suckers are constantly forming. Most hybrids will strike from cuttings if half-ripened wood is taken with a heel attached and inserted in a frame with moderate heat.

So many hybrids are now listed that it is impossible to give even a tithe of the numbers now in commerce, but the selected list given on the opposite page, of varieties of known merit, may be of assistance to those who wish to start a collection. Those which are marked (*a*) are better grown as specimen plants, and those marked (*b*) prefer some shade, at least during the middle of the day.

THE BUSY MAN'S PAGE

Sow China Asters Now.

IT is now time to sow seed of China or bedding asters and we would say a few words in favour of these fine summer flowers. They are so easy to grow and the ultimate result so satisfactory that everyone should try to find a corner for a few at least. The ostrich plume, the Comet and the Californian Giant kinds, with chrysanthemum-like flowers, are probably finest; the Victoria class bears large blooms of compact habit, very fine in the border; the quilled, the peony-flowered and the ray varieties all have their admirers, and the singles, at first despised, are now considered indispensable. We would give particular mention to the Californian Giant, the Late Beauty or Mammoth, Southcote Beauty singles and the Avalanche kinds. At this time sow the seed in a frame—these asters like cool quarters—and transplant the seedlings when they become sizeable; they may even be transplanted outside in a sheltered seed bed and in mild districts they can be sown outside.

MASSED ANNUAL ASTERS PROVIDE BOLD PATCHES OF COLOUR IN THE HERBACEOUS BORDER.

At the same time prepare ground for the plants by digging it over deeply and well; and then add a good dressing of manure or leaf-mould enriched with artificials, or hop manure of good quality. Fork this over late in May, lift the plants from the frame with soil around their roots and plant firmly in dull weather.

Dahlias from Cuttings.

MOST dahlia growers of experience consider that by far the best results are secured by raising these plants from cuttings. This is really a very easy and entirely satisfactory way of securing additional specimens of favourite plants and preliminary steps should now be taken to make sure of sturdy cuttings. Stools or roots that have been in storage through the winter will be showing signs of activity once more. Obtain boxes deep enough to accommodate the roots in an upright position. In the bottom place a thin layer of old leaves, old manure or similar litter. Set out the roots and these may be packed rather closely providing they do not crush one another. Then fill in with loam, leaf-mould, or any fine soil, taking care to leave the crowns or bases of the old stems with not more than half an inch of soil above them. Be sure to preserve the labels of the different varieties.

Give a little water, but not a great deal, and then remove the boxes to a light position in a greenhouse, shed or mild hot-bed. Of course, steps must be taken to see that frost does not reach the young shoots, which will soon arise.

The shoots will grow rapidly and care must be taken to see that these are not unduly drawn; keeping the plants close to the light and as free a ventilation as possible will help to secure sturdy stems. When the growths are 3ins. or 4ins. long they may be cut horizontally below a joint, preferably with a piece of the skin of the old tuber attached. Root the cuttings in soil, which is formed of equal parts of sand and loam or leaf-mould. The cuttings might be inserted singly in very small pots or three or four might be placed round the outer edge of a pot of larger size. Moisten the soil a little and then keep the cuttings in rather a confined atmosphere, such as in a box which is covered with glass. Exposure to direct sunshine is harmful until the cuttings have rooted and some means of shading the glass will be required. Quite soon the cuttings will start into growth and then the more sun they have the better. As required, give more pot room to the young plants and harden off gradually up to the time when dahlias can be set in the open border. Those who have not tried this method will be surprised at the fine plants that result and the abundance of flowers which are produced. Dahlias grown from cuttings in this way come absolutely true to type.

For Planting Under Shrubs.

THE positions under shrubs and trees are so heavily shaded that few plants are able to grow there. One notable exception is the so-called Rose of Sharon (Hypericum calycinum), a species which seems able to keep going with a very small amount of light. One can afford to plant rather thickly, for the Rose of Sharon is inexpensive. Quite often a sufficient number of rooted stems can be secured from a friend, or one can obtain a handful of cuttings. These, if the wood is well ripened, will quickly root in ordinary soil, so that, long before the end of the summer, they are growing freely. A few weeks after setting out the plants it is a good plan to pinch out the tops of the shoots, and this will induce a free branching. The flowers of the Rose of Sharon are large and of a golden yellow colour, and it is astonishing how freely the plant will flower even in very shady spots; and, in any case, the evergreen foliage will soon carpet the ground.

How Far Apart for Thinning.

FOR the proper development of the plants it is necessary that vegetable crops should not be unduly crowded. Experience has shown that the best results are secured if the final distance, after thinning has been carried out, is approximately that given in the table below. The first figure indicates the distance between the plants in the rows and the second figure the space which should be allowed between the rows themselves.

Beans, broad ..	6 by 24ins.
Beans, French ..	6 by 24ins.
Beans, runner ..	12 by 60ins.
Beetroot.. ..	9 by 12ins.
Broccoli	24 by 24ins.
Brussels sprouts .	24 by 30ins.
Cabbages ..	12 by 15, or 12 by 18ins.
Carrots	9 by 15ins.
Cauliflowers ..	24 by 30ins.
Celery	9 by 48ins.
Endive	9 by 12ins.
Kale or borecole .	24 by 30ins.
Leeks	12 by 24ins.
Lettuces.. ..	6 by 12ins.
Onions	6 by 9 or 9 by 12ins.
Parsnips	12 by 15ins.
Peas	Varies with height. Dwarf kinds should be 2 by 24ins.; medium, 4 by 48ins.; tall, 6 by 72ins.
Potatoes, early ..	9 by 24ins.
Potatoes, late ..	12 by 36ins.
Savoys	12 by 15 or 12 by 18ins.
Shallots	6 by 12ins.
Turnips	6 or 7 by 12ins.
Vegetable marrows	Each plant should be allowed a space of 3 sq. yds.

A Wistaria Hint.

ONE of the great faults of the wistaria is its extreme slowness of growth, especially during the first few years. This is especially so in soil which contains a fair amount of clay, and in such positions the plant will hardly develop at all for a considerable time. A great deal may be done to hasten the growth of a young wistaria by preparing the position well at the time of planting. Of course a sunny spot should be selected and a hole of considerable size opened up in the ground. This might very well be three or four times bigger than is really needed for the accommodation of the roots. Fill the hole to about half its depth with loam to which has been added an almost equal amount of sand. Then set the plant and complete the filling with the mixture. In the light warm soil the roots of the young wistaria will be able to grow freely, and the result will be a much more rapid development of the plant above ground than is usually the case.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

How to Prune Your Roses.

LITTLE red and green shoots are already showing on rose bushes, but the wise amateur will have delayed pruning until the end of March. If we examine a rose shoot we notice that it is the buds nearest the tip which have started to grow. If these were allowed to grow on they would most likely be killed by the late frosts, and the flowers, even if they should escape, would be small. To prune, use a sharp knife, or secateurs, and cut back strong shoots to about half their length. Cut away the very thin shoots entirely. Roses newly planted should be pruned a little more severely, say to within three or four "eyes" from the base. Some attention should be given to the symmetrical form of the plant. All old and dead wood must, of course, be cut away. It is important, when cutting back a shoot, to cut off the stem at a bud which points from the centre of the plant.

It will be noticed that some roses make stronger growth than others. This is not the fault of the cultivator, but is due to differences in varieties. Roses which are weak growers require to be cut more severely at the time of pruning. It may be necessary when the shoots have begun to form to remove a few about the middle of May when the flower buds can be seen. The effect of this is to throw the sap into the remaining roses, and finer blooms will result.

These pruning hints apply to roses grown as standards, of the hybrid perpetual and hybrid tea varieties, as well as to bush roses. Climbers require different treatment.

Climbing Roses.

Climbers, such as Excelsa and American Pillar (see illustration), make very long shoots from the base each year. These are retained their full length, and the old flowering wood is cut away. Newly planted roses of this type are best cut back now to one foot from the ground. This will cause young strong roots to grow from the base. Where these varieties are grown as standards young shoots are retained their full length and tied round on umbrella-shaped wire framework in a weeping fashion. Last season's shoots, and also any suckers that spring from the base, are cut away.

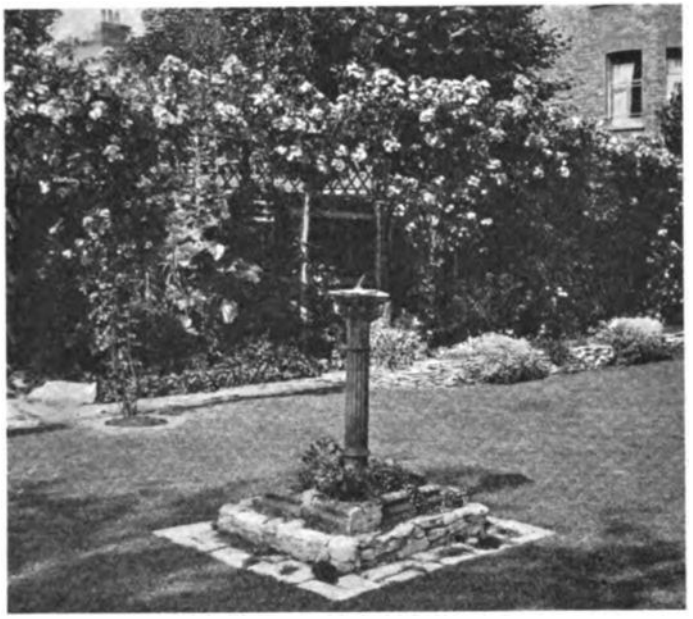
I have had several enquiries regarding the pruning of sweet briars. These should be left about 4ft. high. All old naked roots are cut away, as well as any weak wood. Penzance briars are much more vigorous, and may be allowed to grow 6ft. to 10ft. They throw up long, massive shoots, which may be shortened to the desired height. Where these are used for hedges some of the long shoots should be laid down horizontally to thicken the bottom of the hedge.

The New Sunflowers.

GIANT sunflowers, that turn their yellow "dinner-plate" heads towards the sunshine, are seldom seen in gardens now. Their huge size, and heavy, almost clumsy, heads, make them less pleasing in small gardens than the newer dwarf sunflowers, which have a variety of colourings, and which are just as easily raised from seed. Vivid splashes of colour are appreciated more in the town garden than anywhere else, and those who have not yet made their seed purchases for the year would do well to consider the sunflowers for brilliant effects.

The seed may be sown after the frosts are over, in the position where the plants are to grow; but better results are often obtained by sowing earlier in a cold frame, or in pots protected by a piece of glass. Few amateurs realise how easily seedlings can be raised just by sinking pots into the soil of the border, nearly filling them with soil, and, when the seeds are sown, covering them with small pieces of glass. When the seeds have germinated, remove the glass on fine days replacing it at night until the seedlings are above the level of the rim. Protection at night can be given afterwards by a light covering of straw or newspapers, whenever there is a danger of sharp frost. Great care should be taken when transplanting, to avoid giving a check to the plants.

Varieties.—Carter's Miniature Flowered, Orion and Excelsior are miniature-flowered varieties which are extremely attractive. Mars and Venus are two useful hybrids of Helianthus cucumerifolius and are very suitable for cut flowers. Primrose and Henry Wilde are larger flowered and a little taller in growth.



AMERICAN PILLAR, A BRIGHT PINK CLIMBING ROSE, MAKES AN ATTRACTIVE SCREEN IN A SMALL TOWN GARDEN.

Plants for Shady Places.

I SUPPOSE that the biggest of all problems to the town gardener is the problem of the shady garden. Even where houses do not shut out the sun for the greater part of the day, there are usually neighbours' houses and gardens so near that, in order to get a little privacy in the garden, trees and tall shrubs have been planted wherever possible. These trees, grown to a good size, tend to cast shadows over most of the garden, and as a result it is generally only the very large garden which can boast many hours' sunshine in the day.

The shady garden tends to produce excess of foliage and few flowers. It is, therefore, necessary to exercise caution in manuring, bearing in mind that stable manure, leaves, spent hops and other organic manures are leaf producers. This class of plant food should be reduced to the minimum in the shady garden, but we may use the maximum amount of phosphatic food, which produces flowers. Bone meal and superphosphate of lime are suitable.

Among a very large selection of plants which would grow successfully in the shade, even in the congested parts of a town, we may mention doronicums, the beautiful Campanula persicifolia (Telham Beauty), gladioli in variety, Hyacinthus candicans, tradescantia, phlox, Solomon's Seal, Primula auricula and Meconopsis Wallichii. Even under the drip of trees one or two plants can be grown. Arenaria balearica will carpet stones in such a position. Hardy cyclamens will also succeed under trees.

Bulbs of all kinds will, of course, succeed in the shady garden, such as hyacinths, daffodils, scillas and so on. A few shrubs will also flourish, the St. John's wort, daisy bush (Olearia Haastii) and Sarcococca ruscifolia being specially recommended.

Constant stirring of the surface soil is as important in the shade as in the full sunshine, for it allows more air to penetrate to the roots of the plants. If left alone, the soil in shady gardens tends to become sour, and the plants begin to die off. Another point to remember is to keep the plants clean by constant syringing. The water used should not be too cold, and should be sprayed liberally on to the plants in the evening, particularly after a dry, hot day.

Why Not Plant More Shrubs?

IN spite of the hosts of new and beautiful shrubs that have been brought by plant collectors from the ends of the earth, one very rarely sees them in the average garden. Yet many of these shrubs will grow luxuriantly in town and suburban gardens. Take, for instance, the lovely Chinese shrub, Forsythia intermedia, the golden bell tree. It has been cultivated for many years in this country, and no shrub is more easy to grow, or more charming when in bloom. March is a good planting month for deciduous shrubs, such as the flowering currants, lilacs, etc. The middle of April is better for the planting of evergreens. Planting must be done with every care. Many amateurs buy good shrubs, plant them carelessly and then blame the nurseryman because free growth does not take place. Shrubs require just as much care in planting as fruit trees. Assuming that the ground is already well dug to a good depth, a hole should be made rather larger than sufficient to accommodate the roots. Use the previous soil mark as a guide to the depth at which to plant—not forgetting that the soil will sink slightly after planting. After spreading the roots out evenly, fill in loose soil, and make it firm by treading. Put in a small stake about the same height as the shrub, and tie it securely. This is desirable, even with shrubs which will stand alone when established.

It is quite possible by a judicious selection, to have shrubs in flower every month in the year, even in a small garden. A few which would flower in sequence in a mixed shrubbery would be yellow forsythia, purple Daphne Mezereum, Cydonia japonica, broom (cytisus), lilac, mock orange (philadelphus), Spiræa arguta, ceanothus, Olearia Haastii, Hydrangea paniculata, wych hazel and laurustinus.

WORK IN THE FLOWER GARDEN

Perennial Lupins from Seed.

THE perennial lupin, Lupinus polyphyllus, is a fine plant for anyone in the unfortunate position of having to fill a large, newly made herbaceous border. No matter what the soil, or how it has been prepared (and in these new borders the work is often scamped), this perennial can be depended upon to produce its spikes of flowers. The present time, when the growth is just pushing through the soil, is a very good time in which to plant. Roots can be purchased from any nurseryman at a fairly cheap rate, which, while making a very effective display in the first season of planting, will surpass itself in splendour in the second and succeeding seasons.

When a very large and long border has to be filled, however, even so cheap a plant as the lupin is apt to come rather expensive if the number runs into a hundred or so plants. Those who are content to wait a season may obtain this number of plants from a packet of seed at only a trifling cost. Against this advantage must be placed the fact that if a colour scheme is being planned, it is not safe to rely upon an uniformity of colour from seedling plants. The flower is so beloved by bees that cross fertilisation of the seed is bound to take place. Of course, in the mixed border this production of hybrids is of no consequence, and a very fine effect can be cheaply produced in this manner, coupled with the possibility of the production of one or two entirely new specimens. This possibility was foreseen by Mr. Downer, who for some years has been hybridising the lupin, until he has now produced a range of colours which the older gardeners never thought possible. They include a rich, deep pink, Downer's Delight, a variety of the pale pinks; light and dark blues; some fascinating shades of mauve, biscuit, yellow, garnet, aquamarine, turquoise and opal blues, together with a number of bicolors in rose and amaranth; pink and white; yellow and purple; and numerous other combinations, which are exquisite both in the border, or as cut blooms.

So unfixed is the lupin with regard to its progeny that seed saved from, say, a deep pink bloom, such as Delight—and one plant will produce some hundreds of seeds—will throw very few plants which truly represent the parent.

The seed is cheap, easily handled and easy to raise without heat. A mixed packet of seed will produce an amazing variety of colours. Drills are drawn an inch deep in an open piece of ground, choosing a sunny position, the seeds being spaced at intervals of 2ins., sowings taking place in April and May. Should the raiser be impatient, and wish to see the colour of the seedlings in the first season of sowing, the seeds may be dibbled into boxes or pans of compost in March, and placed in a cold frame. Germination soon takes place, and the resultant seedlings can be pricked out into a trial bed, or nursery row when about 2ins. high. Most of the seedlings will throw one or more spikes in late summer, when the weeding out of the undesirables can take place.

Those sown in the open ground may be left in position until autumn, cultivation simply consisting of keeping free from weeds. The plants will then be good specimens, having a series of long tap roots which should be placed in a downward direction when planting.

The first season after transplanting will produce quite a fine display of bloom, but this is no criterion of what may be expected in after years. The seedlings should be planted in groups of three, allowing a foot between each plant. In the second season, one of these plants should be lifted and planted in another part of the border. In the third year, only one plant should be allowed to remain at a station, for, by that time it will have so increased as to require nearly a yard of space to permit of its development. When this occurs, the plant should receive a mulch of decayed manure, for the soil is almost certain to have become impoverished by the two preceding years bloomings.

The only objection which can be found to this fine plant is that it leaves rather a gap in the border after blooming. For this reason it is a good plan to keep a few tall dahlias in large pots, which can be planted near the lupins after the seed stems have been cut down. Failing this, one of the tall anchusas can be placed within a foot or two of the lupins. If the seed pods are removed as they form, a further period of bloom can be obtained; but it is not so good in quality as that seen in early summer. It does, however, extend the blooming period, especially when the plants are fed with liquid manure.—CLARENCE PONTING.

A CLUMP OF PERENNIAL LUPINS GROWN FROM SEED.

Nothing looks finer in the middle of the border than a bold group of lupins with their tall and elegant spikes of the most delicate colourings. They can be planted now or else raised from seed.

A Fine Half-Hardy Annual.

PHLOX DRUMMONDI is one of the very finest half hardy annuals, although it is probably less commonly grown than almost any of the bedding annuals used in garden decoration. Its range of colour is extremely wide—from purest white to deepest crimson, with every conceivable intermediate shade.

Although of somewhat fragile growth, this phlox will stand much more buffeting about by summer storms than will the majority of summer flowers. Even if beaten to the ground and the flowers splashed with earth, the return of sunny weather soon induces them to send forth a new crop of bloom. In addition to their usefulness as bedding subjects, these phloxes are also suitable for arranging in vases for indoor decoration.

One great secret of success in the growing of P. Drummondi is to give them the best possible cultivation and not merely sow and leave them to take their chance. With this end in view they should be sown in boxes of light compost in gentle heat during March, or if a heated greenhouse is not available they may be sown in boxes in a cold frame at the end of March. In either case they must be pricked off into other boxes as soon as they are large enough to handle and grown on steadily in a cool position. They should be hardened off gradually until they can withstand full exposure to the sun outdoors. It is a good plan to nip out the top of each plant when about 3ins. or 4ins. high; this ensures a bushy growth and a wealth of bloom.

It is as a subject for filling small beds on lawns that Phlox Drummondi excels, and if the beds are deeply dug and well prepared, such situations, if in full sun, suit it admirably. The plants may be put out at a distance of from 4ins. to 6ins., as the best effect is obtained by close planting, the ground being covered more quickly, and the heads of flowers appearing at a more uniform height. A shady or half-shady situation or a stiff clay soil are not favourable for this plant and under such conditions only poor results are to be expected.

In addition to its value as a summer bedding subject, the annual phlox is also excellent as a pot plant and may also be used for furnishing hanging baskets.—T. H. E.

The Autumn-Flowering Ceanothuses.

Present Treatment to Ensure a Fine Floral Display.

CEANOTHUSES fall naturally into two distinct classes; those that bloom in the spring and those that bloom from July to October. These two groups require different treatment to obtain good results and it is largely owing to misunderstanding on this point that results in amateurs not being successful with their cultivation.

The spring-flowering ceanothuses require very little in the way of pruning and this should be done immediately after flowering; in this respect they differ widely from the autumn flowering group, which produce their inflorescences from the current year's wood in much the same manner as do the autumn-flowering spiræas. This latter group of

Digitized by Google

ceanothuses requires pruning in spring, March being a suitable time to perform the operation. Cut the previous year's wood well back; in the case of strong shoots to within 7ins. or 8ins. of the base and when dealing with weak wood cut back to within two buds of the base. Any branches which are weakly should be removed entirely and strong new growths encouraged to take their place. After pruning, a light top-dressing of well rotted manure may be applied with advantage.

It is advisable to root cuttings and commence with a new stock when the old plants begin to fail. Cuttings taken from young shoots early in July and inserted in a sandy compost in a warm propagating case root readily. Remove any bloom which appears during the first year as this assists in the formation of a good plant. A rich, rather light loamy soil is the most favourable for ceanothuses, and the best effect is obtained when they are planted in groups of six or more plants of a variety. As subjects for beds on lawns they are extremely useful, while the stronger-growing kinds may be grown against trellises or walls; it only being necessary to secure the main stems to the supports and allow the young flowering branches to hang gracefully. This latter method of culture is to be recommended for very cold localities, where it is necessary to protect bushes in the open during severe weather.

The best species of autumn-flowering ceanothuses are C. americanus and C. azureus. It is, however, the fine garden hybrids raised from these species which are the most useful and beautiful for garden decoration. Among the finest of these are: Gloire de Versailles, blue, large heads; Perle Rose, rose; albus plenus, double white; Albert Pittet, rosy-lilac; Indigo, dark blue; Bijou, blue; Brilliant, purple; Fleur d'Ete; and Ceres, rose. On reference to nurserymen's catalogues many other beautiful varieties will be found.—T. H.

A Double Use for One Border.

THE beautiful Spanish irises are popular plants in all gardens, their culture is easy, the bulbs are inexpensive and the lovely flowers are delightful for house decoration. Owners of small gardens, however, often find it difficult to afford room for these charming bulbs, for, although very decorative at flowering time, their season of bloom is short, and after it is past, the beds look bare and desolate at a time when all the garden ought to be gay.

This drawback can be easily overcome by sowing a suitable annual to succeed and conceal the remains of the irises, the annual chosen must be of sufficient height to hide all the unsightly stems, as cutting down either leaves or stems would spoil all prospect of bloom for next season.

A very pretty and rather uncommon annual for this purpose is Omphalodes linifolia, or Venus's navel-wort; it has charming white flowers resembling forget-me-nots, and the foliage is glaucous.

In March or early April when the irises have pushed up their slender spear-like growths to a height of 5ins. or 6ins., the seeds can be sown very carefully among them and when the seedlings appear they should be well thinned out to allow them to make vigorous and sturdy growth.

The first illustration shows a long narrow border of irises as they appeared in full bloom in June, and the second picture, taken in August, depicts the good effect and perfect concealment given by the graceful plants of omphalodes.—I. S. T.

AFTER THE IRISES HAVE FINISHED FLOWERING THEIR PLACE IS TAKEN BY OMPHALODES, WHICH CAN BE SOWN IN EARLY APRIL IN THE OPEN BORDER.

A LONG NARROW BORDER OF SPANISH IRISES IN FULL BLOOM IN JUNE.

Renovating Old Borders—An Eleventh Hour Necessity.

IS there any hope for old borders, containing a variety of hardy flowering plants which at the moment are badly in need of overhauling and taking up and dividing, doing well this summer? This is a question one is sometimes asked by those who have been prevented from getting on with the work until the season is advancing. The answer is not easy, and one must make the best of a bad job. As it is not possible to lift many of the subjects, some, at least, that have overgrown can be reduced in size, and thus prevent further encroachment. Such things as solidagos, starworts, achilleas, galegas, may bear portions being cut away, but in the case of deep rooting plants like gypsophila, kniphofias, eryngiums, and peonies, that have now got well into growth, it is unwise to attempt to disturb them. One may, however, afford them temporary relief until autumn, by forking the surface soil, and introducing fresh soil with which a little old manure has been incorporated, but beyond this, one cannot do much without harm following. Borders that are known to be worn out, which in most cases means that they have not been trenched for many years or dug for several seasons, should have the first attention in the autumn, taking a portion up at a time and dividing the clumps and replanting the best with as little delay as possible. What is possible for them in order to tide them over another flowering season can only be of a temporary character, and nothing short of clearance and deep digging should be deemed good enough; still, the help of mulch and forking will benefit, even though it be done at the eleventh hour.—F. W.

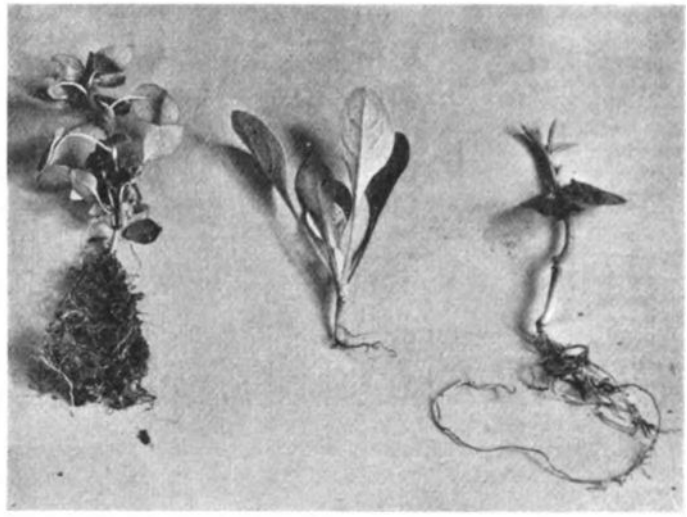
HOW TO GROW HARDY ANNUALS

Sow during the next few weeks in the open ground, if the weather conditions are suitable, for a brilliant summer display.

HARDY annuals are undoubtedly *the* plants *par excellence* for the garden novice to try his hand upon. For one thing, seed is comparatively cheap, and even if failure results with some kinds, the monetary loss is very small. Again, they flower the first year from seed, and this is a consideration with the rather-apt-to-be-impatient amateur. Raising annuals from seed is a good preliminary to the raising of choicer and more difficult plants, and much can be learnt from the sowing of even a packet of the humble nasturtium or Shirley poppy. Almost every type of root system will be met with among annuals, and so practice will be gained in the art of transplanting seedlings. When transplanting, it will be found that annual poppies, eschscholtzias and many others, have long, tapering tap roots, and these plants rarely do much good after a move, unless this is carried out very carefully. Others, nigella and alyssum may be cited, produce masses of fibrous roots, and these kinds may be moved with the greatest ease. Another lesson the growing of annuals will teach is the great value of keeping dead flowers picked off. Take sweet peas alone (though it is true of all other annuals); it is well known that these will go on for weeks and weeks producing fine flowers *if the blossoms are cut regularly*, but once let the seed pods begin to form, there is an immediate lessening of blossom production, and even those that are produced are poor in colour and length of stem.

It may be necessary to define clearly what constitutes an annual plant. This is a very simple matter; an annual plant is one that is raised from seed, grown on, flowered and has died in the course of a single twelvemonth; or, in the majority of cases, considerably less than this, many being sown during April and cleared away as spent and useless by the following October. Annuals are divided into two main classes, hardy and half-hardy (H.A. and H.H.A. of catalogues). Hardy kinds may be raised from seed sown outdoors from March until June, but half-hardy kinds must be sown under glass in early spring, or outdoors during the early part of May. Catalogues always state clearly to which class a plant belongs, and the real novice is advised to try those marked "H.A.," for the first year at any rate. It is true that some confusion exists over certain annuals; dimorphotheca and Swan River daisies, for instance, are variously described as hardy and half-hardy, and in such a case sowings should not be made until the end of April or early in May.



THE DIFFERENT TYPES OF ROOT SYSTEMS.
On the left is a fibrous-rooting subject which will transplant easily; on the right, two tap-rooting subjects which will not transplant successfully, and should be sown where they are to flower.

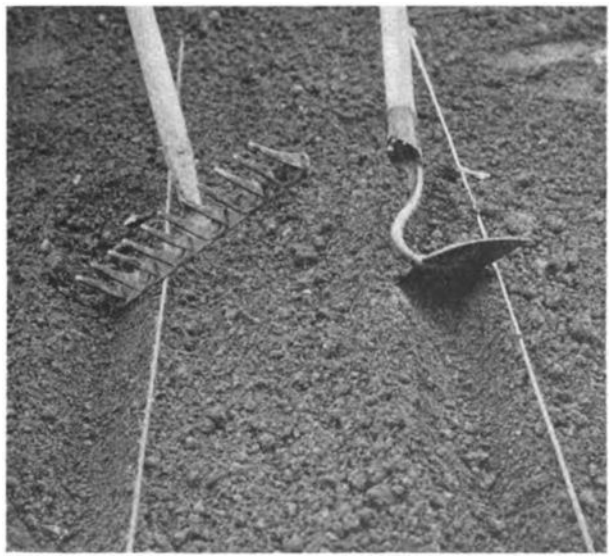
As regards the raising of annuals, it cannot be too strongly urged in the first place that seed be obtained from a reliable firm. A good strain of seed is half the battle in the raising of all plants, and is well worth the slight extra outlay involved. Late March and early April are favourable times for the sowing of all true hardy annuals, but weather and soil conditions must govern this to a large extent, while of course, sowings may be made earlier in the south than in the north. If the ground be wet and pasty, or the weather cold and frosty, time will only be wasted in sowing seed. It will be far better to wait until the end of April

Sowing the Seed.

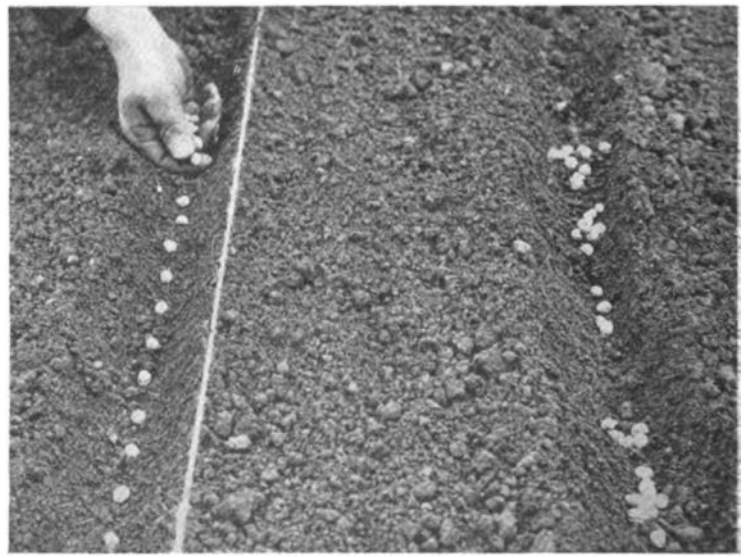
For the beginner, it is usually better to sow the seeds direct in their flowering positions, but all those annuals with fibrous roots will transplant well, and may, if necessary, be sown in a nursery bed of prepared soil, being moved on to their flowering quarters when of a manageable size. A second sowing may be made in early May for a continued display of blossom, while from a third sowing in early June, one often has a bright display in late autumn, but frost is apt to cut this short just at the height of its beauty. As mentioned above, most of the half-hardy sorts may be sown outside in early May, when they will come into blossom rather later than those raised under artificial heat.

The correct depth for sowing is a great stumbling block to the novice, the usual fault being to bury the seeds too deeply. To prevent all possibility of mistake, let it be clearly understood that even the largest seeds, such as sunflower and nasturtium, only need to be buried 2ins. deep, while the smallest ones, poppy and clarkia, for instance, need only the slightest covering of soil. It must be remembered that germinating seeds, like all living creatures, breathe in air, and if they are sown too deeply they are stifled and soon rot off.

Another pitfall for the novice is that of thick sowing. Seed germinates so exceptionally evenly nowadays that there is no need to allow for faulty sprouting. Sow reasonably thinly, so that each plant has sufficient space



TWO METHODS OF MAKING THE SEED DRILL.
With the rake and with the hoe. A line will be found useful as an aid to cutting a straight edge.



THE RIGHT AND THE WRONG WAY TO SOW SEEDS.
Large seeds, like nasturtiums, should be sown about two inches deep, while dust like seeds should only just be covered with soil.

Digitized by Google

to unfold its seed leaves, and thin out superfluous plants as occasion arises. In this way, and this way only, will sturdy seedlings be obtained—seedlings that will soon outstrip in size and vigour those that are allowed to remain overcrowded, and fighting one against the other for light and nourishment.

It should, perhaps, have been mentioned before that deep digging is essential when preparing the ground for annuals, and should be attended to some time before the sowing or planting out takes place. The height to which a plant will grow is no criterion of the depth to which its roots will penetrate, and even the dwarfest plants will appreciate a deep root run. Soil dug to a depth of two spits will give very good results, especially if decaying leaf matter be mixed with the bottom spit. Rotted manure must also be included in moderate quantities. Too rich a soil, however, tends towards the production of coarse, sappy growth at the expense of flower production, and should be avoided at all costs.

Having got the seeds duly sown, watering is the next problem that confronts one. If the ground be nicely moist, there is, of course, no need to water artificially, but if the weather be dry, water should be applied through a rosed can during the evenings. It is best to avoid this practice as far as possible however, as continued applications render the ground surface hard and caked. After the seedlings have appeared above ground, much can be done towards the retention of moisture by hoeing between the rows at frequent intervals.

For the final positions, assuming the seedlings have been raised in nursery beds, a sunny or partially sunny spot should be chosen. Very few annuals will flourish where they can get little sun, and it is waste of time and material to plant them in such positions.

Many gardeners are apt to think that as annuals are such short lived plants, they will flourish without any special soil preparation and that they may be poked away in any odd corner. Really, the reverse is true; with such a short life, only eight months or so, it is obvious that they must be grown under the best possible conditions if they are to develop a vigorous root and leafage system, with a consequent plethora of brightly coloured blossom.

The plants must be given plenty of space in their final quarters, otherwise good results are quite impossible. Properly placed, they will flower profusely over a long period, and moreover, will cover the ground far more satisfactorily than if crowded up together. The taller-growing kinds, such as lavatera and sunflower, must be planted at a distance of a least 18ins. to 2ft., while even the smallest kinds should not be closer than 4ins. to 6ins. It is quite impossible to give in a short article the distance each kind should be apart, but a safe rule to follow is to plant each sort half as far apart as it grows tall; *i.e.*, 1ft. tall, 6ins. apart; 18ins. tall, 9ins. apart, and so on, in some cases this plan fails, as with dwarf spreading plants, such as alyssum, which only grow a few inches high, but must nevertheless be planted at least 6ins. apart. When planting out, a dull, cloudy day should be chosen, so that the plants will not flag, while if no rain seems likely, a good soaking should be given with the watering can or hose. If the water is applied to the base of the plants it will do much towards settling the soil round the roots, and consequently these will take a hold much quicker.

Subsequent culture consists chiefly of regular hoeing, which will not only keep the weeds in check, but also help to conserve moisture, as well as allow air to permeate through the upper soil. Staking is also important, and if this is done early, there will be no sign of artificial support when the plants have reached their full size. A good general fertiliser may be lightly sprinkled over the ground, and hoed in, at regular intervals when the seedlings are growing freely. When flowers are produced, attention must be paid to the removal of all dead and fading blossoms, if continuity of bloom is to be kept up.

The variety of uses to which annuals may be put is practically unlimited, and whether it be for bed or border, rock garden or window box, trellis work or edging purposes, cutting or fragrance, there is always a wealth of material available in the annual world. Whatever the colour scheme desired, annuals can always be found that will fit in with the prevailing shades, and they will do much towards keeping up a long display of blossom.

For the garden novice, for the gardener of limited means, and for the owner of the new and as yet rather bare looking villa garden, annuals can be recommended as the cheapest, showiest and most easily grown of all flowering plants. Given proper treatment, they will equal, and even surpass, in brilliancy and length of flowering season, the choicest of our bedding, border and rockery perennials and tender plants.

B. D. S.

PANSIES AND VIOLAS FOR BED AND BORDER

When, How and What to Grow

IN his lecture on "Horticulture at the Cross-Roads," Mr. William Cuthbertson, remarked that the development of pansies and violas has been largely the work of Scottish growers. The history of the viola, as Scottish people probably know, began in 1859, when James Grieve crossed Viola lutea of the Pentland Hills with show pansies. John Baxter started a little later and in 1874 Dr. Stuart of Chirnside crossed Viola cornuta with Blue King bedding pansy and thus began the work which gave us Violetta, Sylvia, Border Witch and many other charming things. They were succeeded by John Smellie, Busby; A. Ollar, Campbeltoun; Alex Lister, Rothesay; and Robert Fife, Edinburgh, and to-day the interest is maintained by the members of the Scottish Pansy and Viola Association. The members, who meet once a month in summer, are not a numerous body, but they are inspired with a degree of enthusiasm which is not equalled by larger societies. They set a high standard in judging the merits of the seedlings submitted at each meeting. The maximum number of points awarded by each judge is, for size, colour, texture and form, 12, and a first-class certificate is only awarded on a net average of 9 points and upwards, while an average of 6 justifies a first-class certificate. The leading raisers to-day are working men residing in widely scattered country towns and villages, and included in that category are Alick Cochrane, Fauldhouse; A. and W. Stevenson, Dunaskin; A. Frater, Kirkliston; William House, Barrhead; Alexander McAlpine, Tollcross; and James Paul, Killearn. Mr. W. Dobbie, Renfrew, the secretary of the society, also deserves mention for he has raised a jet black viola with a silken sheen, and the blooms are probably the biggest ever seen among violas. It will be exhibited during the coming season.

WILLIAM BARR, A FINE WHITE VIOLA WITH WELL SHAPED FLOWERS.

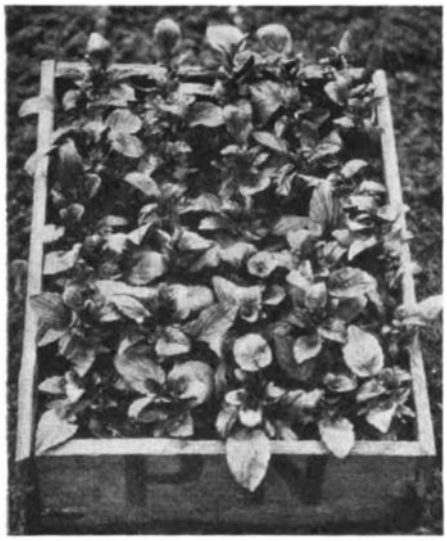
In the successful culture of show pansies and violas there is nothing better than a good heavy loam, well drained and with cow manure incorporated. Dig it in some time in autumn and in spring dig over the ground again and apply a liberal dressing of bone meal. About the third or fourth week of March, before planting, rake in superphosphates, which contribute to the production of short-jointed, hard growth. Avoid if at all possible those big, sappy, leafy plants which never give you good flowers.

The best time to plant is from the third week in March on to the end of April. Arrange the plants 9ins. apart in rows running across the narrow bed, each containing four plants. Keep the plants at the end of each row 6ins. from the side. Keep the surface of the bed on the same level as the path except in the case of sandy soil, where it should be kept a little below that level.

As regards the plants themselves, treatment varies according to the constitution of the particular variety. If the habit of growth is good, allow three stems to each plant, but where growth is weak a single stem is sufficient and, of course, all side growths must be removed as they grow.

September is the best time for taking cuttings. Prepare a rooting medium consisting of equal quantities of loam, leaf-soil and sand with a ½in. layer of sand on the surface. Make the rooting medium firm and water it

Digitized by Google



A BOX OF CUTTINGS TAKEN LAST SEPTEMBER READY FOR PLANTING OUT NOW.
The plants are robust and vigorous.

PLANTING OUT IN THE BED.
The plants should be arranged about 9ins. apart in rows. Each row should contain about four plants, depending on the width of the bed.

thoroughly through a fine rose the night before the cuttings are inserted. Subsequent treatment consists principally of providing shade in sunny weather.

While little growth is apparent for three weeks after removal to the open, the plants are making root growth and begin to make progress towards the middle of May. If it is the intention to grow pansies and violas for show purposes, take off the side shoots and flowers in the beginning of June. Give the plants a complete rest and discontinue disbudding a fortnight before the show. Ithemic guano has a beneficial effect when watered in prior to the show, but a good stimulant that will serve the same purpose consists of ½ oz. each of sulphate of ammonia, sulphate of lime and sulphate of iron to 2 gallons of water. The plants also respond to a top-dressing of short manur worked in round the plants about the middle of May.

The pansy maggot is the chief enemy that growers have to contend with from the middle of June until the end of July. Heat and moisture seem to favour the hatching of the eggs, which are laid round the neck of the plants. The usual symptoms of attack are to be seen in the sleepy appearance of the plant, followed by blue discoloration. Finally, it turns over and dies. Even the fibrous growths of deep-rooted plants are attacked at the very bottom of the root system. So far no cure has been discovered.

The following varieties may be taken as representing the best :

VIOLAS.

Dark Selfs.—W. Ferguson, Kathleen Coudry and Milton Jumbo.

Yellow Self.—John Adamson.

White. — William Barr, one of the varieties that has stood the test of time. There are other good sorts, but they do not possess the same substance.

Stripes.—Jack Milner, Mrs. Walter Nisbet and Robert Black.

Marbled.—Mary Spiers.

Rosy Helio.—Chris Littlejohn, big and reliable, the best of its colour.

Banded.—Molly Gibb, Donald McDonald and Edith Cavell (creamy white).

Edged.—Mrs. James Ritchie, Malcolm Milner and Mrs. James Scalley.

Cream Self.—William Gibb.

Reddish.—Sir Edward Grey.

Nondescript.—Peggy Ramsay.

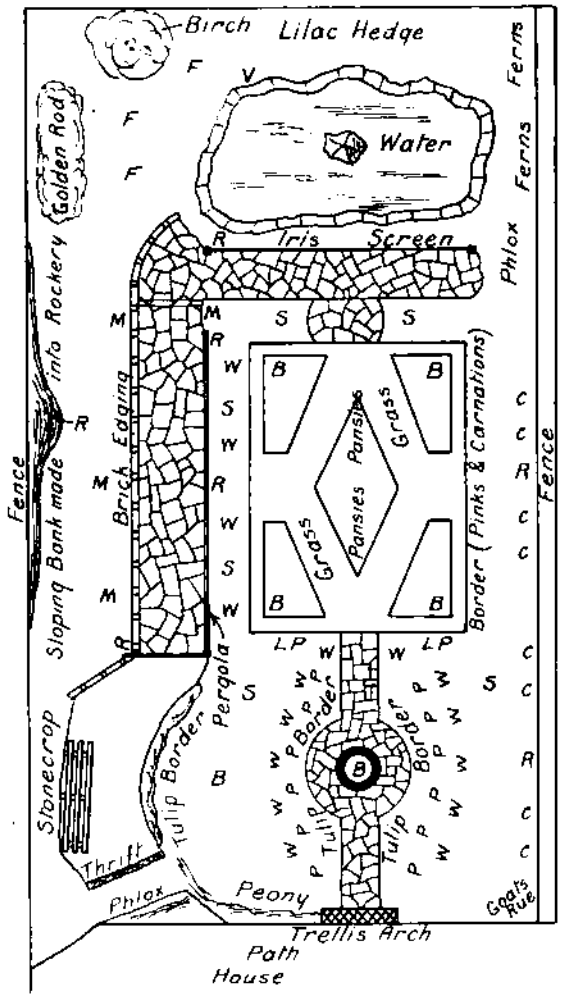
PANSIES.

The best of the 1927 novelties are John Hynd and Mrs. Robert Brooks ; two good introductions of 1926, James Garrow and Mrs. J. Whiteford ; and in general collection, George Hunter is one of the finest pansies in cultivation ; John Greig, Jean Wister, Mrs. Aleck McAlpine, Mrs. A. Frater, Robert Allan, Mrs. Tom Weir and Mrs. A. B. Cochrane.

WHAT OUR READERS SAY

A READER'S GARDEN.

SIR,—I enclose a rough plan of my small garden, which possibly may be of some use to many of your readers. It is roughly 30ft. by 15ft. and gives an idea of what can be done in a small space. This makes a very pretty little garden. The crazy path is made of old bricks and pieces of cement that I found in the garden and an old wall that bordered one part of the garden. The lilac hedge is kept clipped to stop it from growing too high. The brick border is made by standing the bricks on end and sloping them. This is quite an effective border and looks neat. Although the ramblers run practically round three parts of the garden, the two side fences are open ones, so that it gets plenty of air. I mark under the various plants I have at present growing. There are, of course, a number of other plants, especially on the rockery.



B Bush roses, S standard roses, M small myrtle trees, W wallflowers, F ferns, V violets, LP London pride, P polyanthus, C chrysanthemums, R bushes of rosemary.

I will, at a later date, send you photographs of the garden before and after bloom. I send this hoping it will help other of your readers to make their gardens attractive and perhaps suggest new designs for themselves. Wishing your paper every success, I remain a very satisfied reader who has found it a great help. — V. F. WHICHELLO, *Croydon.*

PEAT IN THE GARDEN.

SIR, — While I agree with "A. E. F." (page 174), that peat "is not essential to the well-being even of ericaceous and other peat-loving plants," I should be extremely sorry to do without it. No doubt rhododendrons can be and are grown successfully without a trace of peat in the soil, leaf-mould serving as a very good substitute. But peat has this advantage over leaf-mould that it harbours no slugs or other injurious creatures, whereas every barrowload of leaf-mould contains eggs and larvæ of many species which it is not desirable to introduce to the garden. True peat is chiefly formed through the growth,

Digitized by Google

saturation and decay of sphagnum and hypnum moss, and when freshly cut for fuel consists of about 80 per cent. of water and is heavily impregnated with humic acid. To apply it in that state would be highly injurious, but let the sods be stacked and dried, then broken up, pulverised with a riddle and exposed for some weeks to sun and air and you have admirable material for making a compost. Used in this way for seed pans it may be noticed how the rootlets of seedlings attach themselves to grains of peat in the compost.

The substance described by "A. E. F." as lying 2ins. or 3ins. deep in the woods of Berkshire is not peat, but humus, the ordinary forest soil.—HERBERT MAXWELL, *Monreith*.

A SCHOOL CHILDREN'S FLORAL EXHIBITION.

SCHOOL GARDENING.

SIR,—Many of your readers will be interested in the accompanying illustration, which depicts an annual flower show in which the exhibitors are all children. The plants are all given by the L.C.C. to the children attending the school (Kennington Road, Lambeth, London), and soil is also given. The scholars provide their own pots.

On an appointed day in May a procession of hundreds of children, each armed with an empty pot, marches off to the Botanical Supply Depot. Here they are shown how to pot their plants, after which each child takes his or her plant home to be tended carefully until the day of the show. Last season, when this photograph was taken, three hundred and thirty of the scholars brought in their fully grown plants for exhibition, the best cultivated specimens receiving prizes and other awards. The plants included salvias, mimulus, nasturtiums, lobelias, stocks, calceolarias and petunias. This school also holds a bulb show each season, the bulbs being bought in quantity, and retailed to the children at a low price.—R. S.

[This is an aspect of gardening which, in our opinion, should be carefully fostered. It will do much to create a love of flowers and plants and gardens, which is one of our national heritages. The scheme and the workers engaged in it are deserving of every encouragement and material assistance.—ED.]

THE USE OF VITAGLASS.

SIR,—As one of the oldest converts to the new glass which admits the ultra-violet rays of the sun, may I suggest another most useful manner of applying its unique qualities at this season of the year? My wife and I have carried out some simple experiments with seedlings, comparing the growth under identical conditions of seedlings screened by Vitaglass and ordinary glass. The Vitaglass seedlings germinated before the others and showed a much taller, sturdier, growth. This seems to open a field of usefulness in glazing greenhouses where specially valuable show plants are being grown or where it is desired to get very early produce, such as strawberries for market.—W. KERR RUSSELL, *Newcastle*.

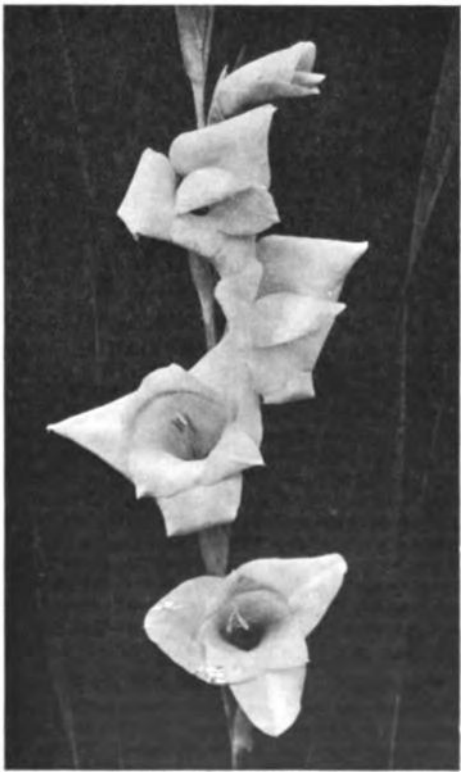
GLADIOLI: VARIETIES for INDOOR DECORATION

OF the two most popular types of gladioli, large-flowering varieties and primulinus hybrids, the latter are the more valuable for general all-round usefulness as cut flowers. Both types may be exceedingly beautiful in their proper spheres when nicely arranged with due regard to their form and colour in suitable vases, bowls or other receptacles. If grace and daintiness are essential, "prims," are, of course, the more effective; but when lightness is of secondary consideration and colour all-important, few flowers can equal the large-flowering gladioli for splendour and sheer brilliancy of coloration. Hints on arrangement were given in a previous article in THE GARDEN of March 19th, and it is proposed in these notes to call attention to varieties of the two types suitable for the purpose.

No varieties of autumn-blooming gladioli catalogued at the present time can justly be condemned as worthless for indoor decoration, but some are very much better than others. In procuring corms (or "bulbs," as they are usually termed) one's choice of varieties must be largely determined by individual taste as regards colours and by their suitability for the particular purposes one has in mind. In these notes, it is impossible to mention many kinds, but I give the following list irrespective of their age or cost; decorative value alone, as I see it, being the only consideration.

LARGE FLOWERING VARIETIES.

As a general rule, my personal taste inclines to "one vase, one colour," but some really charming blendings and contrasts are easily attainable. In white varieties, we have not a very wide choice. *White Giant* is the most popular, but for decorative work I prefer *L'Immaculée*, which is a more refined spike and consistently *pure white*. It is a fine decorative gladiolus when arranged alone or as a contrast to the reds, scarlets and purples. Creams, creamy pinks and yellows are most useful decorative shades, blending admirably with almost all other colours, particularly well with the orange and salmon tones. If arranged alone, these light and delicate shades may be further enhanced by inserting a spray here and there of some dark foliage such as copper beech or the copper-leaved prunus. Good yellows are rare, but both *Yellow Hammer* and *Golden Measure* will be found effective. *Venus* is a first-class decorative kind, a very delicate shade of creamy white, shaded silvery rose.



SOUVENIR, A FINE PRIMULINUS VARIETY OF CLEAR RICH YELLOW. ADMIRABLE FOR INDOOR DECORATION.

There are many pink shades, from light blush to deepest rosy pink, many of them more or less richly suffused with orange or salmon, others enlivened by a pronounced cream or yellow ground colour. In my opinion, most of the pinks appear at their best when arranged alone, and satisfactory blendings are more difficult to obtain than contrasts. The deeper tones, particularly if they have salmon or orange in their "make-up," are very effective under artificial light. One of the oldest and still one of the best is *Early Sunrise*, a charming shade of salmon pink, coming into bloom very early. *General de Wet* is a delicate shade, a light apricot rose with excellent decorative qualities which is certain to become popular. *Apple Blossom* is appropriately named, its colouring closely resembling that of the apple blossom; while a new one of some merit, *Rosabella*, is somewhat similar but deeper coloured. *Ophelia*, another newcomer, is like *Apple Blossom*, but on a cream instead of a white ground. Two which I confidently recommend are *Mrs. Leon Douglas* and *Mr. W. H. Phipps*, both colours difficult to describe; the former begonia rose, lightly striped flame, and the latter La France pink overlaid rose salmon. *Dr. Van Fleet* makes a fine bunch, its somewhat unusual placement enhancing its decorative value. Its colouring, too, is uncommon and most attractive, rose pink deepening towards the edges of petals on a canary yellow ground. Other good pinks include *Pink Perfection*, *Catherine Coleman* (a beautiful rich coral), *Adelaide de Luxemburg*, the well known *Panama* and *Rose Precose*.

The orange shades will be found invaluable in dull positions and all are beautiful by artificial light. Like the orange scarlets, scarlets and bright crimsons, their intensity of colouring is heightened by the inclusion of a few yellow, cream or light creamy pink shades. *Prince of Wales* must, I think,

Digitized by Google

be well known to all; it is an old variety now, but still one of the most attractive warm salmon pinks in existence. *Thomas Edison* is uncommon, a most charming light coppery salmon. The quaint markings of *Golden West* appeal to me; it is one of those varieties which need a fairly close inspection to enjoy fully. The colour is orange red overlaid gold. *Majestic* is a wonderful colour, a lovely bright shade of orange pink; the great pity is that it is not more vigorous in habit. *Odin* is dependable and an attractive colour, rich salmon with dark blotch. One of the very best is *Richard Diener*, pure geranium pink with a creamy yellow centre, rather expensive now, but sure to become popular later. *Apricot* is an excellent decorative gladiolus which, I feel sure, will appeal to all; it is a soft and most pleasing tone of salmon apricot.

All the scarlet and red shades need light treatment and careful arrangement. They are a very numerous class indeed. Where bold and bright colour effects are required, the following will be found eminently suitable: *Red Emperor*, large-flowered, with a loose placement, but perhaps a shade too dull except when used in well lighted positions. The colour is deep blood red. *Crimson Glow*, richer than the above but not quite so large. *Dr. F. E. Bennett* I believe to be the best of the fiery reds, a magnificent colour. *Chris* is very distinct, and gives a refined spike, its chestnut red colour appeals to most. For size of bloom and majesty of appearance, *Pfitzer's Triumph* is a wonderful orange red.

Perhaps the rose shades do not lend themselves to decorative work as do most of the other tones, so I will mention two only. *Pride of Haarlem*, distinct salmon cherry red, pleasing only when arranged entirely by itself or with a cream variety; and *Bleriot*, much more amenable to blending with others, a creamy rose, with orange throat.

Good blues, mauves and purples are all too scarce, but the following can be depended upon to give satisfactory results as cut blooms. The old *Baron Hulot* is still one of the best dark blues; while, in my opinion, no light blue is equal to *Mrs. Van Konynenburg*. The colour of *Catherina* comes somewhere in between these two, a lavender blue with darker markings. *Herada* is a nice clean tone of mauve, and *Jacoba Van Beiren* a soft purple self. *Purple Glory* will become the most popular purple maroon, a grand gladiolus; and *Anna Eberius*, too, has a certain future. The latter is a first-rate decorative gladiolus of a distinct lavender purple shade. Coming to lighter tones, we have *Byron L. Smith*, resembling a cattleya orchid in colouring, lavender pink with creamy throat blotch, dainty and attractive.

For those who like uncommon colours, there is no gladiolus which I have seen likely to prove more attractive than *John T. Pirrie*. The colour is much more beautiful than can be conveyed in words, a sort of mahogany brown, with reddish brown blotches and a cream throat.

PRIMULINUS HYBRID VARIETIES.

Lighter and daintier vases and bowls may be used for "prims." than for the large-flowering varieties, and they need different treatment. Perhaps I may best convey this by advising readers to forget that "prims." are gladioli and arrange them, for instance, as sweet peas are arranged, and with a fairly lavish use of suitable foliage. There is one cultural point which has a decided bearing on decorative work. If vigorous-growing primulinus hybrid varieties (such as Souvenir) are given elaborate cultural treatment, the result may be coarseness from the decorative point of view; thicker stems, larger flowers and a more unguinly looking spike.

I like all the "prims.," but these are special favourites: *Souvenir*, the best clear rich yellow, *Citronella*, creamy yellow self, a soft pure and clean shade. These two should be planted in quantity, for they may be mixed with most of the other varieties, the orange, orange salmon, salmon and salmon pink shades, without fear of producing anything but a charming harmony of tone. One of the best, perhaps the best of all, is *Salmon Beauty*, ideal both in form and colouring, a lovely shade of salmon on yellow ground. *Xanthia* is a pure orange, glowing and very vivid, which all should grow. *Jewell* is a little expensive at present, but a real gem, light salmon with yellow throat. *Shell Pink*, too, will surely become popular when its price is lower, a charming tone of shell pink. I like it much better than the well known *Maiden's Blush*, a pink which was introduced several years ago but is still good and very popular. *Scarlet Cardinal* is, in my opinion, the best intense brilliant scarlet; but *Vermilion Scarlet* and *Daphne* are both very nice and more reasonable in price. The colour of *Orange Queen* is unique in gladioli, a warm coppery orange yellow hard to describe but most pleasing. *Salmonea* is a general favourite, salmon flushed glowing orange. If grown rather poorly, *Nydia*, a light salmon rose, is delicate and pretty, but good cultivation will produce thick flower stems out of all proportion to the size of the pips (as the individual blossoms are termed). *Orientale* is still more delicately tinted, lemon lightly flushed salmon rose, exceptionally dainty. *L'Exuette* and *L'Yser* are similar in colour effect, the former cherry red with large yellow blotches, and the latter orange scarlet with a decided and clearly defined yellow throat. *L'Ecaillon* is a most beautiful and distinct "prim."—a pure soft salmon with deep rosy blotch. *Orange Brilliant*, one of the smallest flowered of all, makes an exquisitely rich bunch, a wonderful blending of orange scarlet and yellow, almost a bicolor. The old variety, *Hermione* (orange salmon), is one of the most reliable; so, too, are *Sphinx* (glowing orange). *Rosandra* (rich cerise pink), *Psyche* (salmon shaded cerise), *Athalia* (the best orange scarlet) and *Atalanta* (salmon shaded orange). So one could go on, almost entirely through the list of "prims." which are to be found in up-to-date catalogues, without finding one which is not decorative. I have, indeed, nearly overlooked *Alice Tiplady*, a soft orange saffron which appeals to most flower lovers.

Primulinus gladioli should be planted, not by the dozen, but by the hundred, as they will be when their real value for home decoration becomes known to the general public. C. H. A. S.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Starting Begonias.

Many people find it hard, at this time of the year, to get begonias to start evenly. In dealing with hundreds of bedding begonias, I had generally 20 per cent. later than the rest. Now I find that the best way is to place the bulbs "eyes" downwards on sand in a warm temperature for about a fortnight, with no top covering. By that time all the bulbs will be showing growth; they can then be turned and lightly covered, and all will grow on together.—C.

To Protect Your Seeds.

Strands of black thread will protect seed beds from sparrows, but not from the finch family. But if, before putting on the thread, you get a few feathers from a chicken's wing or tail, you will be able to frighten even the finches. Fasten your thread to a stick, so that it will be about a foot from the ground; then about 4ft. or 5ft. along, make a noose, slip in a feather, and draw it tight. Continue adding feathers at intervals all along the row, fasten thread to a stick at the end, and then make sure, by propping up the thread if necessary, that all the feathers swing clear of the ground. They will be continually moving, as the slightest wind affects them.—E. A.

Weeds on Lawns.

The time has arrived when dandelions and plantains are making themselves noticeable and a great disfigurement on the lawns. Now is the best time to deal with them. Take an ordinary mower oil-can, and apply weed-killer from it direct upon the heart of the weed, and certain death will follow. The weed will die away, and before the summer the bare patch left by the plantains' departure will be re-covered by the grass. Place a piece of stick into the spout of the oil-can so that the weed-killer drips out about as fast as you can count. I have found this method an unfailing remedy, and thousands can be done in a few hours.—W. H. L.

Violas for Late Bloom.

When planting out violas grown from cuttings which have been growing in boxes in cold frames, take cuttings where possible from these, plant the cuttings in boxes of soil and put back again into the cold frame. It will be found in a few weeks' time that these will have made good rooted plants and, planted out, will make a fine show of bloom during the late summer and autumn. Where one wishes greatly to increase his stock of violas, this will be found a very excellent method.—J. H. H.

Gilia coronopifolia.

This is a plant that attracts attention in the herbaceous border, but which is very seldom seen. I found it very difficult to flower at one time, treated as an annual. Of late years I have taken to growing it in pots until the flower spikes are well advanced, and then plunged in the border without any disturbance. A light soil and plenty of drainage is essential for this plant. Sown in heat in early spring, grown on and finally potted in 6in. pots, and planted out in July, it will flower in late summer.—F. W. D.

Sowing Valuable Seeds.

When sowing scarce or valuable seeds, sow each seed separately and cover each indention in the seed-box, after the seed is sown, with sharp sand instead of soil, thereby ensuring the air and drainage so vital for successful germination. A larger percentage of big flat seeds will germinate if the seeds are sown edgewise instead of laid flat, when they are much more likely to rot, especially where slow germinating species are concerned. It will be found advantageous for bringing on seedlings quickly to make the lower half of the compost of seed boxes richer than the top half. When giving delicate seedlings their first shift, an egg-spoon can hardly be bettered for moving them with a minimum of root disturbance. In this way quite small seedlings can be transferred to pots without undergoing any apparent check.—C. S.

THE FRUIT AND KITCHEN GARDEN

How to Grow Good Leeks.

LEEKS are among the most wholesome and easily grown vegetables, being subject to few enemies, and when planted out in prepared ground, need less attention than most things. Notwithstanding this, it is hard to understand why so many amateur gardeners are content with indifferent crops, or fail to give leeks the attention that they merit. The average amateur thinks about sowing seed late in March or early April, and, as a consequence, fails to get those tall blanched stems, which only time and good culture can accomplish. This note is not written with the idea of deprecating sowing the seed of leeks even at this late date, as, on the principle that "half a loaf is better than no bread," I would be an advocate for getting seed in, if possible, under a frame light in boxes on light soil, pricking off the young plants when about 2ins. in height into a bed under the frame in which mellow loam and old manure is found. These plants, got out subsequently into their final quarters, will provide something useful at least for the table in late winter and early spring. But why be satisfied with a poor crop, when one may at this time purchase a score or two plants, which are usually sufficient to meet the needs of the average small grower? Nothing pays better as a winter crop in my opinion—based on many years experience, than an early batch of leeks. We are apt to say concerning some vegetables that when they get large, then they become coarse. This is not so in reference to leeks, as the larger they can be grown and well blanched, the more profitable they are for the table.

Preparation of Ground.

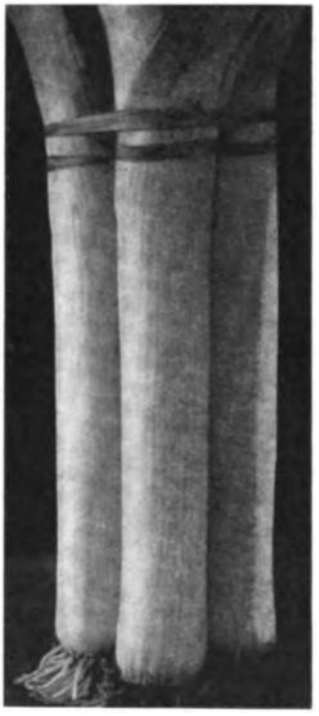
Here again I would utter a word of friendly criticism as to the place and condition of ground for leeks. They are worth something more than the out of the way corner, and indifferent soil some gardeners give them. They deserve the best soil, deep and rich. It is scarcely possible to make the soil too generous for them. Let those who pride themselves on the culture of celery, go to as much trouble in digging out trenches for leeks, say a couple of feet, breaking up the base with a fork, and incorporating with the soil, in filling the trench, what animal manure is possible, planting out the young plants in April or May in single or double rows a foot apart, if leeks of super quality are desired. In getting them to their final quarters, a blunt dibber should be used, into which the plants can be dropped, first pinching out just the tips of the leaves. It is not necessary to fill up the holes with soil, as it will filter in, neither need one be particular about "almost burying" the plants. If the soil has been generously manured they will soon "find their feet" and speedily establish themselves. In the summer when the stems rise well above the surface of the trench, arrangements can be made for—

Earthing up.

This can be done by simply drawing the soil about them, being careful not to allow it to get between the leaves, or they can be "collared" with stiff brown paper, much in the manner that celery is done. Pinching the tips of the leaves two or three times in a season will be the means of thickening them.

Stimulants.

Leeks appreciate stimulants and make good progress. To this end, the manure tub in some convenient place in the garden should have supplies of horse or sheep droppings from time to time, with a bag of soot placed at the bottom, but no stimulant should be applied in dry weather until plants have been well supplied with clear water. The grower is not troubled with insect pests, as is the case with onions and parsnips, for instance, and when once his leeks show signs of growth, he may rest assured that it is up to him to supply their needs in the matter of stimulants, and failures may be left out of count. The biggest stems will give him certain satisfaction that he was wise in getting early sown plants, but the smaller plants from a late sowing will be appreciated too when in the vegetable dish. Between the largest and smallest, it is a question of time-table only, and the earliest sown stand the first chance to show what they can become with good culture. If I may give an incident from my own experience last year for the benefit of someone, perhaps, growing leeks for the first time, it is this. In January, I sowed seed of Sutton's Aquisition in the greenhouse. Plants were pricked out, and in due course were planted in



SUTTON'S PRIZETAKER, A LARGE LEEK OF GOOD FLAVOUR.

prepared trenches in the following April. A friend calling on me when I was dibbling them in, made the remark that they were small, and "lost themselves" in the holes. I asked him to come again in November, when I dug up for him a couple of those same leeks with 15ins. of blanched stems. He could hardly believe that the tiny plants could have developed into such big specimens!

Varieties.

There are leeks—and leeks. It is always best to grow only those with a reputation, as for example, the Lyon, Musselburgh, Sutton's Acquisition or Prizetaker. There is always more satisfaction in taking in hand varieties that have proved their worth.—W. F.

Vegetable Marrows: Preliminary Preparations.

IN days when it was possible to obtain stable manure at a much cheaper rate than now, it was no uncommon thing to find after the garden had been planted in spring, that a heap of manure was left over, and in order to make some use of it, until such time as it was wanted, two or three vegetable marrows were planted thereon. This, I think, gave rise in some quarters to the mistaken idea that a quantity of stable or other manure was necessary for their cultivation. We have learnt different since. The market gardener, who has to keep his eye strictly on economy, grows marrows with very little manure from a stable or farmyard, but he makes use of all the vegetable flotsam and jetsam he can, and digs this in where he proposes to plant. A little stable manure is helpful, but excellent results can be had with Wakeley's Hop Manure also, at much less cost than it takes to procure stable manure. At the present moment, attention should be given to making up beds for the reception of plants a little later. Raised beds have their advantage in a season when wet predominates, but made on the ground one reaps a certain advantage in a dry period. In any case, the position for vegetable marrows should be sunny, away from overhanging trees. May usually is the time for getting plants into their quarters after they have been hardened off, but one must be guided by the weather as to the actual time of making the change to the open ground. In any circumstances, night protection should be afforded the plants for a time by covering them with boxes or pots, as they are the first to feel the ill effects of cold weather. Varieties noted for their small growth, such as Moore's Cream and Epicure, are often as profitable and of better flavour than coarse, large growing sorts. No liquid manure will be needed until after the first fruits have set.—W. K.

Growing Celery in Small Gardens.

TO grow really fine celery taxes the ability of the cultivator to the utmost. In a small garden, where other kinds of vegetables are grown, there is not much space available for celery, but even if there is space, unless the household requirements are great, only a limited number of plants should be grown, but grown really well. Begin by sowing seeds now, or a little later on. Do not wait until the resultant seedlings are grown sufficiently to be planted out before you prepare the shallow trench. Do this work now also. When the trench is ready for the plants it should only be about 9ins. deep, but the prepared soil in the trench should be quite 18ins. deep. First remove the top soil, placing it on one side of the trench, then the lower layer. Return the soil to the trench, mixing with it some well rotted manure, leaving out a portion of the extreme bottom soil for earthing-up purposes in due course, but replace the good soil last for the young celery to be planted in. Sow the seeds very thinly in a mixture of loam and leaf-soil, cover them lightly with fine soil and, finally, with a sheet of glass and paper. But be sure that the resultant seedlings are fully exposed to the light. Water by immersing the seed pan. Transplant the seedlings at an early stage and select those that are equal in size. The young plants should be grown in a nursery bed in a cold frame prior to their final planting out. Allow a 6in. space between the plants in this bed and 1ft. in the trench outside.—HANTS.

Plant Cut or Whole Potatoes?

OPINIONS differ on this point; but there are decisive factors to be considered. Seed sets of a large size will produce stronger plants than small sets. Whole sets will be less liable to contract disease; and, in the case of sprouted tubers it is certainly advisable to plant them whole. Small potatoes do not

Digitized by Google

Produce better crops than large sets. The only advantage about undersized tubers is due to the fact that they are not perfectly mature. If potatoes are quite ripe when lifted, they are not so good for seed purposes. That is why seed potatoes from Scotland, and especially from the far north of Scotland, are of greater value as seed than potatoes grown in a warmer and earlier climate. The Scottish seed has not reached the fully ripe stage when lifted, and it consequently has latent powers for growth which over-ripe tubers do not possess.

Tubers over 2 oz. or 3 oz. in weight may be cut if it is desirable to make the seed spin out as far as possible. If tubers are under 2 oz., or pass through a 2in. to 2¼in. riddle they need not be cut, except in the case of any exceptionally scarce variety.

Large tubers can be cut at the time of planting, but it is undesirable to cut some time before planting. On no account ought cut potatoes to be allowed to become too dry from exposure to drying winds; and they must not be bagged and stored in a place where they will be liable to heat or ferment. Some people dust the cut tubers with lime and sulphur, but no advantage as to growth accrues from it.

Sprouted sets are best planted direct from the boxes they are usually placed in to sprout. They should neither be cut nor bagged.—J. W.

Garden Pests to Kill Now.

EVERY spring, when we look forward to the growth of the young shoots, the early flowers and the formation of the young fruits, we meet with their enemies, too. In some seasons, when we have spells of hot sunshine and cold east or north winds at the same time, many insect pests seem to thrive and multiply all the more. But there are some pests that have been in, or near to, the garden all the winter, and I strongly advise amateurs to turn their attention to them first. I am now referring to shell snails, slugs and woodlice, mainly. In many districts—my own included—shell snails are very numerous. They winter in clusters in old pipes, pots, under boxes, boards, slates, bricks and gravel heaps. All such places should be closely inspected and the shell snails forthwith destroyed. I have destroyed many hundreds of them recently, and it means less damage for young greenstuff a few weeks hence. The same remarks apply to slugs and woodlice. It is astonishing to find so many of these hiding away under odd pieces of boards, bricks, tiles and other objects. Hunt them up and destroy them now. Later on it may be necessary to hunt for them late at night with the aid of artificial light, whereas now we can destroy them wholesale in the daylight—and before they have had a single bite at our tender lettuce leaves, sweet peas and young carrots. Indoors, there are the growing shoots of roses and peach trees: quite clean and free from green or black aphides to-day, almost hidden by them a few days hence. The best remedy is to fumigate the house at regular intervals. Fumigate directly the first few aphides are seen; fumigate on a calm night, and repeat the dose the following or the night but one afterwards. Then, probably, a weekly fumigation will keep the foliage clean. The leaves should be dry at the time, but the floor may be moist.—G. G.

Space Saving Tips.

A MISTAKE too often made in small gardens, especially, is to sow peas and beans in rows alongside of each other. Where space is precious, the beans and peas should be well distributed throughout the vegetable garden, so that other crops may come between. For example, if tall growing peas are sown in multiple rows in a clump, from 5ft. to 6ft. must be left between the rows. Of course, a row or two of radishes, parsley, spinach, lettuce, etc., might be sown between the pea rows. But it is a better plan to make a sort of plot division, hedge, or background, with single rows of peas or beans. Each row should be about 6ins. or 7ins. wide, the peas or beans being scattered broadcast or planted at intervals of about 2ins. or 3ins.

This affords shelter to whatever crops may be growing between. Peas should be sown to come on in succession. If the peas are soaked in soot and water before sowing, the sparrows will not eat them.

In sowing root vegetables, like beets, carrots, parsnips, turnips, etc., see that the ground has been dug deeply or trenched, so as to enable the tap-roots to get down into the soil easily, and so avoid forked or badly-formed roots. A generous dressing of compound fertiliser will generally answer best.

Cabbages, cauliflowers, broccolis, savoys, curly greens, leeks, etc., are more or less gross feeders, and it is well to treat these crops generously. Besides a good dressing of dung when the soil is dug in the winter time, these crops will take an additional good dressing of artificials at planting time. The cabbage tribe will take about 2oz. of superphosphate, 1oz. of muriate of potash and 1oz. sulphate of ammonia per square yard. Leeks may be given 3oz. supers, ½oz. of muriate of potash and 1½oz. sulphate of ammonia per square yard. When planting cabbages and cauliflowers, reject any plants having a knot on the stem. It is well to puddle the roots in soot and liquid manure before planting. Ground for vegetables coming on to be planted out later on should now be got ready and well manured. They require a good dressing to bring them to a full crop.—W. O.

Treatment of Pot-Grown Strawberries.

A FEW early strawberries, especially if they are grown in one's own garden, are very welcome and much appreciated. I never have heard anyone regret the labour bestowed upon the plants when the reward has been a satisfactory crop of luscious fruits. The first part of the work consists of layering and then the potting of the rooted layers. Throughout the winter months the plants do not require any attention if they have been packed in tree leaves, litter or ashes. Under glass, from January onwards, watering, syringing and feeding are the main points needing attention. But there are a few minor details which should not be overlooked by the cultivator. Clear water only is the best for the plants up to the stage when the majority of the fruits are set. If the soil is allowed to get so dry that the foliage wilts badly, the fruits, when ripe, will be, to some extent, deficient in flavour, and very poor in flavour if over-dryness occurs several times. The plants must not be watered with liquid manure when the soil is rather dry, but always a few hours after a watering with clear water. Then there is the work of fertilisation. This can be done at noon with the aid of a rabbit's tail, camel-hair brush, syringing (especially so during sunshine), or shaking the trusses of flowers. Occasional doses of clear soot-water will feed the fruits and help to keep off red spider. Remove the tiny berries and the others will benefit. —HANTS.

Vine and Peach Borders Under Glass.

THE vine rods, the branches and flowers of the peach trees can be seen every time the cultivator enters the houses. Just for the time being the inexperienced cultivator may feel quite satisfied with the general appearance of the trees. If the border soil is in good condition things will be satisfactory. But is the soil all right? The experienced grower satisfies himself on this point early in the year; in fact, he knows its condition all through the winter months. Although the general appearance of the trees may be pleasing now, trouble will come later if the soil is too dry or in a too saturated state. If extremely dry, young peach and nectarine fruits may fall off wholesale and, in the case of the vines, shanking of the berries may be the result. Test the soil now; this can be quickly done by driving in an iron rod down to the drainage material. When withdrawing the rod, do not turn it round, but pull it straight out. If the loam is very dry it will adhere to the rod in the form of crumbs of soil; if it is too wet the rod will be clean and wet and practically free from soil particles. The necessary treatment in each case is obvious. The too dry soil must be watered, not once only, but three times, on alternate days. The very wet border must not be watered again until it is in a normal state, and to help matters lightly ease up the top 4ins. with the garden fork without turning over the soil, or the roots there will be broken. The water-logged border must be dealt with outside the house. If there are drains, see that any blocked pipes are freed from obstruction. In the absence of any system of drainage by pipes, make a hole deeper than the base of the border, but close to it, so that surplus water can drain into it and be taken away.—CHRISTCHURCH.

Protecting Wall Peaches from Frost.

This must be done at once if the fruit crop is to be safeguarded, as the trees are now breaking into blossom.

THE peach is one of the earliest of our fruit trees to come into blossom, and its blossom appears at a season when frosts are prevalent. It is no unusual thing to have the promise of a splendid crop of peaches destroyed by frost.

Peaches in this country are usually grown as trained trees against wall, so that it is possible to protect them from the ravages of frost by covering them up during nights when frost is imminent. Fish netting, old curtains, strawberry netting and similar articles make excellent materials for this purpose.

An easy and fairly inexpensive method is to take an old curtain or curtains of the right dimensions to cover the blossoming portion of the tree and suspend it from the top of the wall after the fashion of a window blind.

Two wrought-iron brackets with notch at end to prevent rod slipping form suitable supports. They should be driven securely into the wall at the required height and distance apart. The curtain should be attached at one end of its length to a rigid iron rod about ¾in. in diameter, or a piece of iron piping will do. To the other end of the curtain a wooden pole or lath should be attached. This is merely to keep the curtain from being blown about by wind, and must not be too heavy, otherwise the curtain will tear.

The curtain can be rolled up easily, and to secure it in position place the iron rod in the sockets provided in the brackets and unroll gently, care being taken not to damage the blossoms. The brackets must project far enough from the wall to allow the curtain to hang freely.

Such an arrangement will keep out quite an amount of frost. During the daytime it should be taken down, allowing the light and sun to get to the trees so that pollination is not interfered with.—H. B.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2887 Saturday, April 2nd, 1927 Price TWOPENCE

A BOWL OF MODERN ESCHSCHOLTZIAS.

THERE are few flowers to equal the eschscholtzias for gorgeous colour effects in either beds or borders. They produce a mass of bloom showing a wide range of the most brilliant colourings which lasts during the summer months. Those who have not grown them should give them a trial in this year's summer bedding schemes. They are easy to grow and although, strictly speaking, they are perennial subjects they are best treated as annuals. Seed should be sown this month in the open ground in positions where the plants are to flower as the seedlings do not transplant successfully. They reach on the average about a height of one foot and are particularly suited for massing in the forefront of the border. Apart from their value in garden decoration they make fine flowers for cutting for the house. Be sure and sow seed of one of the modern varieties this month.

VOL. XCI.—No. 2887. APRIL 2, 1927. PRICE TWOPENCE.

PRIMULINUS GLADIOLI: ARE THEY THE MOST POPULAR?

BEFORE attempting to reply to such an intriguing question, it may be interesting carefully to weigh up those qualities and characteristics of both the large-flowering type and the primulinus hybrids which seem likely to enhance, or detract from, their present and future popularity. Any types other than these two may be left out of the question.

As for the present, it is generally known that the gladiolus is rapidly gaining favour among all classes of gardeners, more particularly among amateurs, who are beginning to realise how easy this exceedingly beautiful flower is to grow, how adaptable, and how useful for decorative purposes in the garden and the home. Its culture demands little or no experience, one simply procures the corms, plants them in the spring, keeps them free from weeds, and in the autumn a satisfactory show of bloom is almost a certainty.

As far as cultural requirements are concerned, neither type under discussion has an advantage, for the same treatment should be given to both. It is in their appearance and their respective value that we must look for differences which really matter. As its name implies, the large-flowering section has large blooms, with wide-open petals, the individual flowers being placed closely together, completely hiding that part of the thick and fleshy stem to which they are attached. The flowers face more or less in one direction, and the larger number of them open at the same time the better.

The primulinus hybrid is very different. Its blooms are much smaller and, instead of the petals being wide open, the top one curves over, forming the "hood" so characteristic of the type. The flower stem is (or should be in representative varieties) thin, but wiry and strong, and the individual flowers, although facing almost the same direction, are spaced fairly widely apart.

There seems to be little difference in their respective value as garden plants or bedding subjects. If anything, there is a slight "credit balance" in favour of the prims., for what may be lost in actual mass of colouring given by the larger flowers and spikes of the large-flowering type, the "prims." more than gain in other directions. In the first place, the large ones are heavy-headed, needing stakes, especially in open positions. On the other hand, "prims." are not so heavy, presenting a smaller surface to the wind and rarely needing other support than that of their own strong, wiry stems. Then again, "prims." (from top size corms) invariably send up two, sometimes three, flowering spikes from the one corm; further than this, these main stems will often branch out, sending out a smaller spike after the main one is over, thus giving a longer flowering period. In the border, the individual spikes of all gladioli are quickly past their best as soon as the bottom floret has faded, but primulinus varieties perhaps present less of a bedraggled and untidy appearance as they are "going off" than the large-flowering.

All gladioli excel as cut flowers, their brilliant colours and wonderful lasting qualities being quickly appreciated. For this purpose there is little doubt as to the merit of the two types. If the lady of the house is consulted, her vote will be for the "prims." nine times out of ten. Their elegant daintiness renders them as adaptable and suitable for indoor decorations, by day or by artificial light, as sweet peas.

A point which must not be forgotten is their comparative cost. On the whole, the primulinus types are the cheaper, for they propagate very quickly and bloom earlier from bulblets than the large-flowering varieties, type for type.

Where the large-flowering class has a distinct and very decided advantage is in its much wider and more comprehensive colour range. One doubts whether there is another flower in existence which possesses so many beautiful and varied hues; but will they always have this advantage over the "prims."? We may expect improvements in colour and new colours in the primulinus section in the near future that are real advances, especially if one has regard to the rapid development and improvement which has taken place during the last few years. We now have an orange self of the same intensity as the Sweet Pea Royal Sovereign, a "white" Souvenir, pinks such as are found in carnations, velvety purples, and many shades of salmons and oranges new to "prims." The large-flowering type has been "worked" for many years, and is logically nearer its particular standard of perfection than the comparatively new primulinus hybrids. Who can tell whether there may yet be evolved a more pleasing form than "prims." exhibit at the present time? We shall surely get "ruffled" or wave-petalled "prims." as in the large-flowered, and hybridists are not likely to neglect wild species in their endeavours to evolve more charming and useful varieties combining the quality of fragrance. In THE GARDEN of March 13th, 1926, a contributor mentioned several African species likely to be of service in this direction. Of a particular species the writer said, "Its stem is as fine as a harebell's," and again, "A quantity of these flowers in a large crystal glass bowl was a sight I shall never forget."

In summing up, and taking all points into consideration, it would seem evident that the "prim." will become *the* popular flower, and this opinion is based, not so much on what they are to-day, but what they are likely to be in a few years' time. Although it may be many years before there is as large a quantity of "prims." grown as large-flowering varieties, there does not seem to be the slightest likelihood that the measure of public esteem enjoyed by the latter will be reduced by the "prims."; indeed, there is little doubt that the popularity of both will increase, *but at different rates*. There is, and will be, no such thing as rivalry between the two; one type will help, not hinder, the other. Their appeal is quite distinct and different, and those who grow one will wish to grow both. Of late years there has been an advance in the purely decorative forms in other flowers such as roses and dahlias, and this apparent tendency of the times is just one other reason why it seems probable that primulinus hybrids are destined to play a greater part in the great future which seems assured to the gladiolus.

This Week's Work

Prune hybrid tea and hybrid perpetual roses.

Mulch raspberries and strawberries with light strawy manure.

Plant gladioli.

Pot up dahlia cuttings now in the greenhouse.

Make further sowings of carrots, beet, onions, celery, broad beans, cabbages, lettuce and radishes.

Roll and then mow your lawn, and trim all lawn edgings.

Sow herbs in shallow drills of prepared soil.

Plant potatoes.

Start taking cuttings of violets in frames.

Stake securely all new-planted trees and shrubs.

We are indebted to Messrs. Sutton and Sons of Reading for the coloured illustration of eschscholtzias which appears on the front cover of this issue. The bowl shows a number of varieties raised by this firm.

CALIFORNIAN POPPIES FOR PRESENT SOWING

Some Up-to-Date Varieties and Novelties of Eschscholtzias

IT is often remarked that eschscholtzias are only flowers suitable for the border and are no use for cutting. But such is not the case, as this pretty little flower makes a very attractive subject for small bowls and vases. Eschscholtzias should be cut early in the morning before the sun has caused the flowers to expand, and if gathered when young they will last for several days in water in a cool room.

The wide range of colours available at the present time make this easily-grown annual (strictly speaking, perennial) a very desirable subject, and as they only grow from 9ins. to 12ins. high, they are useful for small as well as for large gardens.

One of the greatest drawbacks to growing eschscholtzias, and indeed this applies to most annuals, is that they are very liable to get knocked about in bad weather and, consequently, their beauty may be sadly marred during a severe spell such as we only too often experience in the north of Ireland. This defect is more especially serious where the plants are used for bedding purposes, as then the general scheme may be spoiled for at least part of the summer. It is probably wiser not to sow them in very rich soil, as they then become too rank and soft and, consequently, more susceptible to damage. I would, however, strongly recommend readers who have not as yet grown them not to be deterred from giving them a trial, as they are certainly well worthy.

It may not be out of place to mention a few of the many fine varieties offered and in each case the catalogue descriptions are given :

The Geisha.—Inside of petals brilliant golden, outside orange crimson ; the petals are prettily fluted and it is a really beautiful sort.

The Mikado.—Brilliant orange-crimson ; received an award of merit from the R.H.S.

Mandarin.—Bright orange, shaded with crimson.

Vesuvius.—Bright wallflower red, both inside and outside the flower.

Gaiety.—Petals prettily fluted, very pale cream cup, backed crimson.

Lovely.—Bright pink suffused with salmon, satiny sheen.

Carmine King.—Rich carmine rose.

Mauve Beauty.—A beautiful pure mauve.

Robert Gardiner.—Double orange with fluted petals, compact growth.

Ruby King.—A deep rich ruby, dwarf habit.

Queen of the Buffs.—A pretty shade of clear apricot buff.

Rose Queen.—A rich rose, flowers very freely produced.

The foregoing give a very varied selection of up-to-date varieties, and should provide colours to suit every taste.

The following novelties are offered this year, and I will give their introducer's description for the benefit of those who are on the look-out for something new :

Oriental Queen (Dobbie and Co.).—The inside of the flower is a beautiful shade of pale buff, while the outside is rich raspberry red. The blooms are very large and when fully expanded often measure 4ins. in diameter.

Winsome (Carter and Co.).—Clear coral pink on cream ground, flowers of good substance and charmingly fluted.

Enchantress (Carter and Co.).—Semi-double, rosy carmine on cream ground, strong grower.

There is one other eschscholtzia entirely different from any of those mentioned to which I should like to draw attention, and that is a miniature variety growing only about 6ins. high and producing small yellow flowers in great profusion. This eschscholtzia is offered by Messrs. Sutton and Sons, and is appropriately named Miniature Primrose. It is recommended for rockeries and edgings, and is certainly a delightful little subject that is worthy of increased popularity.

Although the list of varieties given above is fairly representative, it is by no means complete, but it is sufficiently lengthy to show what a wide field there is from which to choose. For those who do not care to trouble with named varieties, the mixed selection of hybrids offered by most of the leading seedsmen may be recommended.

With regard to hints on cultivation, no very definite instructions or recommendations can be given, as so much depends on the locality, nature of the soil and earliness of the season. In cold bleak districts with heavy wet soil it would be inviting failure to risk early sowing outside ; but, generally speaking, advantage should be taken of a fine spell anywhere from the latter part of March to the end of April or early in May.

It is unfortunate that so many annuals are such difficult subjects to transplant, and the eschscholtzias may certainly be included among the number, for in this district it is difficult to be sure of even results, and in some seasons almost complete failure may be experienced, due to an unexpectedly cold or wet spell following the sowing of the seed, and to the ravages of slugs. This year I am experimenting by sowing a few seeds in "T.P. Raisers," placing them in the conservatory until germination has taken place, and then removing them to the shelter of a cold frame. In this way I hope to be able to transplant without unduly disturbing

AN ATTRACTIVE EDGING OF ESCHSCHOLTZIA QUEEN OF THE BUFFS.

Digitized by Google

the roots of the seedlings, and thereby obtain better and earlier results.

Last Spring I used a light covered with the glass substitute, "Windolite," for one small frame, and found that seedlings flourished amazingly well under it and seemed indeed stronger and healthier than those under glass.

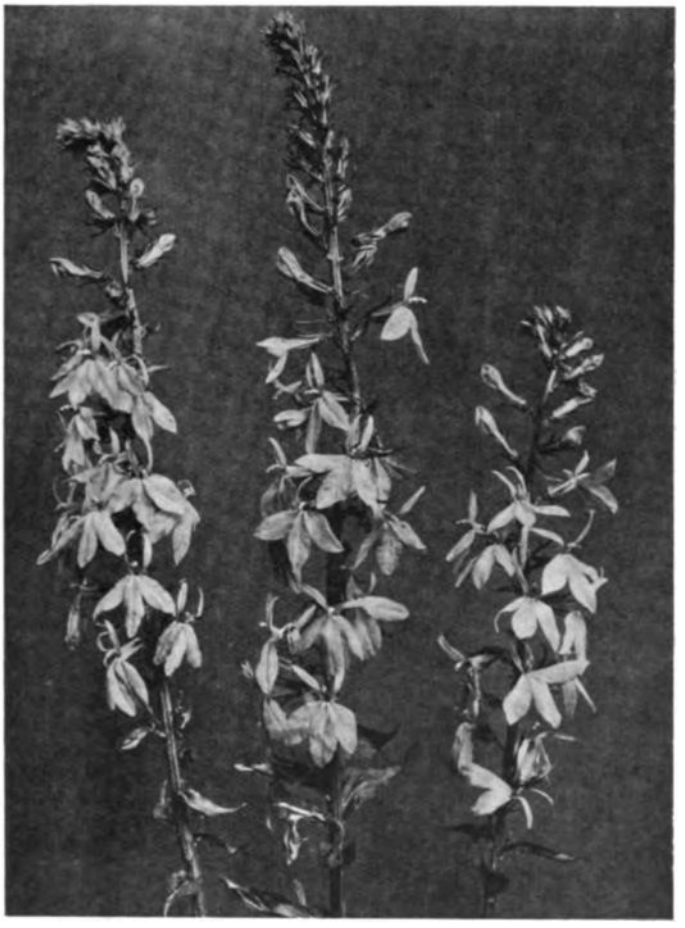
I hope in the foregoing remarks that I have not over-emphasised the troubles and difficulties of the would-be grower, and that, in consequence, some may be deterred from trying this charming little flower. To any such I would say: The outlay for a trial packet either of a named variety or a good mixture is small, and that success will mean a display of colour in the garden and a generous supply of flowers for small vases and bowls that will last over a considerable period. Where it is decided to risk sowing the seed direct in the flowering quarters, I would advocate caution in the selection of the site and would recommend the choice of small clumps in the front of herbaceous borders where any gaps that might occur could be easily filled with other subjects. Remember that the eschscholtzia belongs to the poppy family and, thrives best and is most effective when planted in situations which derive full benefit from the sun. CECIL M. BAILEY.

HARDY HYBRID LOBELIAS FOR THE BORDER

VISITORS to the Holland Park Show last year were favourably impressed by the brilliantly beautiful hybrid lobelias shown by Messrs. Ladhams of Southampton. These hybrid forms are perfectly hardy, and are of the utmost value for massing by the waterside, where their brilliantly coloured flowers make up a picture of rich and unusual beauty. They should also be extensively used for planting in the border, in preference to the half hardy cardinalis and fulgens, with their many varieties. The selected forms of pure L. syphilitica species are good for the wild garden, and for naturalising in moist spots, or even in the border. They are totally unlike any other herbaceous plants, their densely packed spikes of pure white, light or dark blue flowers surmounting the rich masses of broad robust foliage, being very attractive, especially when seen in some semi-wild part of the garden.

Early Planting Essential.

The planting of these lobelias should be carried out in early spring, April being a good month for this job. All perennial lobelias delight in a rich moist soil, so it is necessary to dig in plenty of well decayed manure and leaf mould, or cow dung in a very light soil. Copious supplies of water should be given in droughty periods. I have grown L. cardinalis very successfully in a dry spot by sinking a fairly large pot between every three or four plants, and filling this up with water once a day, or twice per day during very dry weather. In this way, the water goes straight to the roots, and there is not the surface caking that occurs when overhead watering is practised. Lobelias are not averse to a weekly dose of liquid manure once the flower spikes have appeared, but always give clear water first, unless the soil is in a naturally moist condition. It is necessary to transplant the hardy lobelias regularly each spring, as soon as they are starting into growth, but on no account should they be divided in autumn or winter, or loss is bound to result. As a small number of plants are likely to be ravaged by slugs during the dead of winter, ashes or sand should be thrown over them in late autumn.



LOBELIA B. LADHAMS WITH VIVID SCARLET CRIMSON BLOOMS.

A Selection of Varieties.

B. Ladhams is undoubtedly one of the best of the hardy group, with huge spikes of the most vivid scarlet crimson flowers, rising in splendour above the bright green foliage. This variety is of especial value on account of the many side branches it throws out, each with its due proportion of flower spikes.

Mrs. Humbert is a pretty variety, growing into a bushy plant, and simply smothered with masses of small rosy pink flowers at the right season. It is one of the cheapest of them all, and would look well in bold clumps in the water garden, to say nothing of its great value for brightening up a shady border.

Salmon Queen is somewhat similar to the preceding, but with paler blossoms that are, perhaps, a trifle larger than in Mrs. Humbert. There is a need for a better plant in this shade, for Salmon Queen is not free enough, neither is it as bushy as Mrs. Humbert.

The purple shades are rich and sumptuous, one of the finest in this colour being Purple King, with well balanced spikes of the most intense shade of purple; it is a variety that should be found in every collection, large or small. Delight is of a much paler shade, but nevertheless, it is a charming variety, and should not be overlooked. An added attraction is the dark foliage, which, generally speaking, is lacking in these hybrids. Mauve Queen is of an attractive aubrietia purple, the flowers being of medium size. It ranks second to Purple King among those of this shade, in my estimation, but probably not everybody will agree with this opinion. Bluebird has comparatively massive spikes in quite a good shade of blue, and the individual blossoms are not too large. This variety I should certainly place among the best six for garden decoration, for it is undoubtedly the best blue form I have seen.

Carmineus has medium sized flowers of a bright cerise colour, and can be strongly recommended for general planting. As it only reaches a height of 2ft. or so, it will be found of value for planting round the rockery pool, where some of the taller growing sorts would look rather out of place.

Of a distinctly deeper shade of cerise than the preceding is Rose Queen, and the foliage is very dark. It is of sturdy branching habit, and in freedom of blossom leaves nothing to be desired.

Shirley Beauty is a fine sturdy plant, with quantities of large, rich crimson flowers, and having dark plum-coloured foliage. The blossoms are many shades deeper than those of B. Ladhams, and the plant grows a full foot taller than this variety, reaching a height of 4ft. to 5ft. In habit it is ideal, being sturdy, free flowering and erect in growth.

Kimbridge is a new variety that will make a name for itself as soon as it gets known. It has a tendency to crimson foliage, while the rich purple maroon flowers are individually as large as Shirley Beauty, and produced in massive spikes.

Besides the sorts described above, there are about half a dozen other named varieties, and they are all reasonable in price, so there is no need to run to great expense when making up a representative collection. For those who wish to try these plants, the following six may be recommended as representing the cream of the collection: B. Ladhams, Mrs. Humbert, Purple King, Bluebird, Shirley Beauty and Carmineus; to these may be added Kimbridge, for it is unique in shading, stature and foliage.

The only drawback to these hardy hybrids is that they lack the richly coloured foliage of the more tender species, with one or two exceptions noted above. Mr. Ladhams seems optimistic about correcting this fault, and it is rumoured that he already has some promising dark-leaved seedlings of the hardy type.

A point that should have been touched upon before is the great value of these lobelias for permanent bedding. The half-hardy forms are brilliant plants for growing in a shady bed, but they must inevitably be superseded by the less troublesome hardy sorts when these become more generally known. Readers who are already acquainted with the tender perennial lobelias will need no urging to try their even more brilliant hardy cousins, and to those who know neither, my advice is that they lose no time in making a first acquaintance. B. D. S.

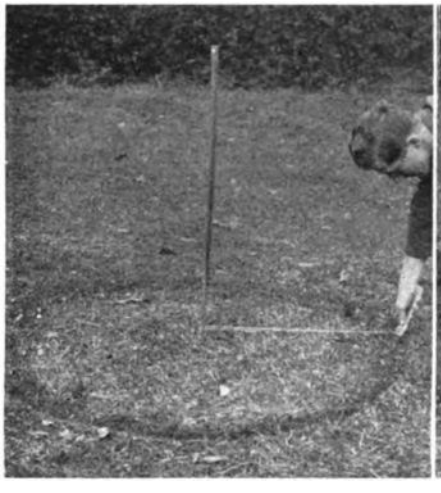
PLANTING EVERGREEN SHRUBS

Select, if Possible, Showery Weather for Planting

THE planting of hardy shrubs is a subject requiring some care and forethought, from the fact that on it depends to a considerable extent the future health and welfare of the bushes. In such a very large and varied family of plants, gathered together from many parts of the world, the best time for moving the different subjects, as one would expect, extends over a considerable period. With a fairly representative collection, planting can proceed almost uninterruptedly from September to May when ground and weather conditions permit.

More care is necessary in the planting of evergreens—shrubs which retain their foliage throughout the year—than with shrubs which are leafless in winter. With evergreens, breathing and transpiration of moisture are active throughout the year. In midwinter the leaves are dependent on the roots for an uninterrupted supply of nourishment, whereas deciduous shrubs can carry on in winter if the root system is checked.



1.—MARKING OUT THE RING BEFORE PLANTING A SPECIMEN SHRUB ON A LAWN.

2.—THE SHRUB PLACED ON A SLIGHT MOUND AND THE ROOTS CAREFULLY SPREAD OUT.

3.—PLANTING COMPLETED. NOTE THE COLLAR OF THE SHRUB IS AT SOIL LEVEL.

September and early October, or April and early May, are the best seasons for planting evergreens. At either of these times, and particularly in spring, when new growth is beginning, the roots are very active and recover more quickly at these two seasons from the disturbance and loss of roots in transplanting. To compensate to some extent for the check in the supply of moisture and nutriment through disturbance and loss of roots, it is worth while shortening the branches considerably in an endeavour, as it were, to balance matters. I have seen hollies and yews which have suffered badly at the roots reduced by pruning to half their original size and quickly recover from the check, whereas if left their full size, with a sadly depleted root system, death was almost inevitable.

Preparation of the Ground.

Unlike the planting of annual and perennial plants, which is a periodical operation, the intention when planting most shrubs is that they shall remain undisturbed for years. Hence the preparation of the ground is of the first importance. Begin by breaking up or trenching the soil to a depth of 18ins. to 2ft. The nature of the ground must be the chief guide in its preparation. A good loamy soil need only have a dressing of farmyard manure or bone-meal. To a light gravelly soil add some fairly heavy top-spit loam in addition to the manure. Heavy clay soils are improved by the addition of plenty of coarse grit and builders' lime with leaf-mould, if available.

The unsatisfactory appearance of shrubbery borders can, in nine cases out of ten, be traced to neglect in the preparation of the ground previous to planting. We read much more frequently about the trenching of the ground 2ft. or more in depth for sweet peas and roses than in the planting of shrubs, though of no more importance in their successful cultivation.

Likewise, when preparing stations for single specimen plants on lawns and elsewhere, dig adequate holes both in depth and width. There should be every hope of success in transplanting fairly large evergreen specimens with good balls of soil attached to the roots from one part of the garden to another.

In well managed nurseries the stock is transplanted at least every second or third year. The idea of this is to confine the roots to a comparatively small area, as all long straggling roots are cut off, inducing the formation of a mass of fibrous roots. This must tend very largely towards success in planting.

The deep planting of many shrubs is very harmful, as the soil round the bark tends to start decay at the "collar" or ground level, leading to the ultimate death of the plants. Subjects most likely to suffer from deep planting and burying of the stems include rhododendrons, lilacs, hollies and brooms.

Another important point is that shrubs succeed very much better when the feeding roots are near the surface in warm aerated and sweet soil than when buried deep down in, it may be, poor ground. Some shrubs are able to overcome the defect of deep burying of the stems by developing new roots from the buried portion. This is a matter that is only learned by experience. The safe way is to plant the shrubs no deeper than is evident was the case in the nursery. Should this not be sufficient to hold the bushes firmly, support with a stake, rather than bury deeply.

Always dig holes wider than the length of the roots to allow of them being spread out to their full extent. Work fine soil among the fibrous roots as the hole is filled in so as not to damage the feeding roots of evergreens more than is unavoidable. Tread or ram light soil firmly, heavy soils need only moderate firming—it will gradually settle more firmly.

Avoid planting in heavy clay soils during wet spells. A very good practice is to lay a stick across the hole when the plant is placed in position and before filling in the soil. It is then readily seen whether, when filled in, the stem will be buried or not, and the plant can be lifted or lowered accordingly. I find a 10ft. or 12ft. wooden rod useful for the purpose.

The watering of evergreen shrubs as soon as conveniently possible after planting is very important, whether the weather is wet or fine. Should the weather be dry, a good watering three or four days before transplanting home-grown bushes is worth while. If the roots of the plants are at all dry on arrival from the nursery, thoroughly saturate with water; while, if the ground is not ready for immediate planting, heel the roots in soil temporarily without undue delay.

Planting Evergreen Hedges.

Readers who have recently moved to a new house and garden will be interested in the planting of hedges. The second half of April and early in May is a very good time to plant Cupressus macrocarpa, the evergreen oak (Quercus Ilex), Berberis stenophylla, B. Darwinii, Escallonia macrantha, Pyracantha Lalandei, Lonicera nitida and laurustinus (Viburnum Tinus), all of which are valuable subjects to form evergreen hedges.

For at least ten days or a fortnight after planting evergreens, spray the bushes each evening after hot dry days.

These newly-planted shrubs, particularly those of any appreciable size, should be watered until they are established. This not only assists in settling the soil around the roots but makes available an abundance of moisture for the disturbed roots. A. O.

THE HARDY ANNUAL MALLOW.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

THE CHINESE LANTERN.

Lavatera (Mallow). THE annual forms of lavateras are becoming more widely grown every year. They are extremely showy for planting in large beds, and to see them to the fullest advantage they should be given ample room. They grow 3ft. and more in height, and flower-stems may be cut with 12ins. or 18ins. of blossoms, which are of service for the decoration of large vases, set off as the flowers are by handsome foliage. They are hardy annuals, which are best sown in April in the place where they are wanted to bloom, as they do not take kindly to transplanting, and this involves the seed being sown very thinly, the weakliest plants being pulled out. As they take up a deal of room when fully developed, 18ins. of room from plant to plant is not too much. A sunny position and a well drained, fairly good soil are necessary to grow the lavateras successfully. They bloom from July to September.

Pentstemon. ALTHOUGH a perennial by reputation, the pentstemon is often found to be too tender in many districts for one to winter them out of doors, and the safest plan is to lift old plants in autumn and winter them in a cold frame, or—what is often practised to-day—to take cuttings in September, dibble them in a bed of sandy soil and keep them in the frame until spring. Pentstemons can, however, be treated as annuals, raised from seed sown in pans of light soil in a greenhouse in warmth at once, and plants from such a sowing will be ready for getting out of doors by the end of May. They grow about 2ft. in height, are prolific in blossoms, and make effective displays planted in groups or beds. A sunny position and a well drained loamy soil to which well decayed manure and leaf-soil have been added before planting out is what suits them.

Helianthus (Sunflower). THE day of the giant sunflower is largely a thing of the past, and in its place a race of comparatively dwarf varieties with dainty blossoms suitable for cutting for table decoration has become popular. They comprise both double and single forms. Some are perennials, some annuals, and are from 2ft. to 6ft. in height. Both are easy of cultivation. They do best in a rich deep soil, as they are gross feeders, and a sunny aspect is necessary for them. Some of them commence to bloom in July, and the garden will not then be without them until October. Perennial forms propagate from division of roots, which may be carried out in late autumn or March. Annuals can be sown either in warmth of a frame then, or out of doors on a warm border in April. Transplanting should take place as soon as they are large enough, and they must be given ample space in their blooming quarters.

ONE OF THE BEST OF THE PERENNIAL SUNFLOWERS, HELIANTHUS RIGIDUS.

Physalis (Chinese Lantern or Winter Cherry). THESE are very popular, not because of any attraction in the plants themselves, or of the flowers, but owing to the pods, or calyces, which succeed the flowers, being highly ornamental and appreciated for their value in a dried state for indoor decoration. Physalises present no difficulty of culture to the amateur, as they will succeed in any ordinary soil, either in a sunny or partially shaded place in the garden. They vary in height from 1ft. to 2ft. They are hardy perennials which can be propagated (1) from seed sown in any light soil either in the open ground or cold frame in April, (2) from cuttings taken from the plants during summer, treated similarly to seed, except that it is often necessary to afford them shade for a time until rooting has taken place; and (3) by dividing the roots in spring or autumn. Stems should be cut with pods intact as soon as they colour.

Aconitums (Monkshood). THESE are hardy perennials which thrive best in a shady or half shady position in a garden, and any ordinary soil that is moist, answers for them. The dwarfest grow about 3ft. in height, others attaining 6ft. to 8ft., bearing flowers of varying shades of blue and white and yellow. Propagation is by division of roots in late autumn or spring and from seed sown out of doors in a shady border. Flowering time is July and August. While the aconitum is an attractive plant in bloom, it has one bad trait in its character and this is, that roots, leaves and flowers are poisonous.

Digitized by Google

THE BUSY MAN'S PAGE

April Reminders.

A FINAL sowing may be made of broad beans. Dust a handful of superphosphate to the yard run along the drill before sowing.

A row of dwarf French beans may be sown in a warm spot towards the end of the month. Put the seeds in 4ins. apart and cover with about 3ins. of soil.

A sowing of the turnip-rooted beet may be made at the end of the month.

Carrots may be sown for the general crop.

Cauliflowers may be planted out from boxes towards the end of the month.

Young celery plants should be transplanted to 4ins. apart and a sowing made for a late crop.

Towards the end of the month transplant onions raised in boxes to the open ground after enriching the soil and making it firm.

Make the main sowing of parsnips.

Sow mid-season and late sorts of peas.

Complete the planting of potatoes.

Raspberries may be mulched with short manure. Newly planted canes should be shortened to within a foot of the ground before growth starts.

Strawberries will also benefit by a mulching with straw manure.

Hardy annuals of many kinds may be sown out of doors. Asters, stocks and other half-hardy sorts should be transplanted 3ins. apart in boxes as soon as they develop their true leaves. Roses may be pruned.

Gladioli may be planted 3ins. deep in well dug soil early in the month.

Any renovations of the lawn, such as sowing or turfing, should be taken in hand.

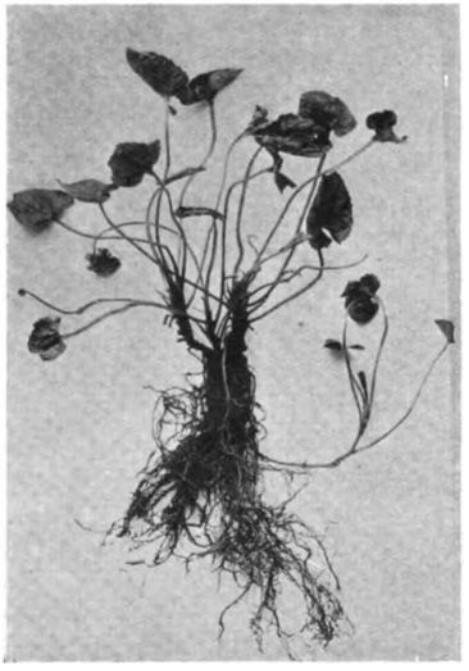
Potting Rooted Cuttings.

CUTTINGS of heliotropes, fuchsias and other semi-shrubby plants which were inserted some weeks ago will now be rooted, and no time should be lost in getting them potted off. Generally it is advisable to give each a pot about 2ins. in diameter for a start, and, from thence, transferring them into larger pots as growth proceeds. In any case the pots must be clean and well drained, and, for the first potting, use a soil with a larger percentage of sand than that employed for the final potting. Such young plants usually need their tops pinching out in order to induce them to branch. On no account should this be done simultaneously with potting. Either do it a week before the removal or ten days afterwards, by which time the specimens will have recovered from the shock of transplanting.

A VIOLET PLANT AFTER FLOWERING, READY FOR DIVIDING.

How to Propagate Your Violets.

DURING this month and in May, violets must be propagated, for, although this plant is a perennial, vigour and a high standard are only ensured by raising fresh stock. This may be done by means of runners or suckers; such runners are freely produced by old plants, but each plant should be allowed a limited number for obvious reasons. Either plant the runners in boxes of rich compost or, when well rooted, direct into their summer bed. Another plan practised is to divide up the old plants and replant them in April. An early opportunity may be taken to prepare the bed for these new plants. A medium loam is best; too porous a soil has to be improved by the addition of turf and manure or, at least, manure, while heavy borders must be ameliorated by incorporating much gritty matter as well as a liberal dressing of manure; light soils, like cow or pig manure best, but, for heavy land, use horse litter. If the garden has a "fiery" light soil, plant the new plants in a north aspect; if the soil is stiff and retentive, let it face south, while in the case of medium soils, an east or west or an open border will serve. Give the plants lots of room in a rich soil; the singles must be 12ins. to 15ins. apart; the doubles 10ins. to 12ins. Get the planting done as soon as possible and water the soil nightly if the subsequent weeks prove very dry. In a light soil mulch some litter or short manure round the plants and always keep the soil in good tilth by hoeing.



A PORTION REPRESENTING THREE CROWNS.

Hardy Annuals to Sow Now.

NOW is the time for the sowing of many of our most popular bedding plants, such as asters, ageratums, East Lothian stocks, lobelia, etc., where artificial heat is available.

DIVIDED PORTIONS, EACH AN INDIVIDUAL CROWN WITH ROOTS ADHERING.

RUNNERS DETACHED FROM THE OLD PLANT.

Those who have not the advantage that a heated house affords need not be deterred from the sowing of flower seeds for the decoration of their gardens in summer. There are dozens of the most beautiful flowers from which to choose which can be raised without the aid of artificial heat, some of them only requiring the protection of a cold frame in the months of March and April. In fact, the bigger part of them may be sown on the spot where they are intended to flower; many fine bold, artistic and floral effects being thus obtained. The attached list may be of some assistance, although it could be much enlarged upon. Among the tall or medium plants there are the following: Alonsoa Warscewiczii, scarlet, tall, 18ins.; Bartonia aurea, yellow, 18ins.; Coreopsis Drummondii, yellow, 18ins.; centaurea (blue cornflower), 2ft.; clarkia varieties, 20in.; candytuft in variety, tall, 12ins.; godetias in variety, 12in.; larkspurs, from 1ft. to 3ft.; nigella (love in a mist), blue, 18ins.; nasturtium in variety, tall; mignonette, 12ins.; Phlox Drummondii in variety, 18ins.; and sweet peas in all colours. Suitable dwarf plants for edgings to the above mentioned are as follows; Alyssum minimum, white, 3ins.; Linaria aurea, yellow, 10ins.; candytuft, dwarf (any colour); nemophila, blue or white, 8ins.; Nemesia nana compacta, 9ins.; verbena in self-colours, 10ins.; and Virginian stocks.

All the above seeds may be sown on the open ground in April, making an exception, perhaps, of larkspurs and nemesias, which are better raised in a frame to allow of them coming into flower earlier.

The main cultural attention they will require will consist in thinning out of the seedlings of the taller plants to from 7ins. to 9ins. apart and the dwarfs from 4ins. to 6ins., and in keeping them all entirely free from weeds.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Distinctive Shrubs.

SUBURBAN gardens frequently show a feast of blossom weeks before the open country puts on its spring dress. The more sheltered position has a little to do with this, but it is also due to the fact that the early-flowering shrubs and trees are much favoured by the suburban gardener. Almond and peach blossom are well known in London gardens, and also the Japanese quince (Pyrus japonica) bird cherry (Prunus Padus) and purple-leaved plum (Prunus cerasifera var. Pissardi). None of these grows too rapidly or attains too great a size for average gardens, and even a single specimen adds distinction and character to its surroundings.

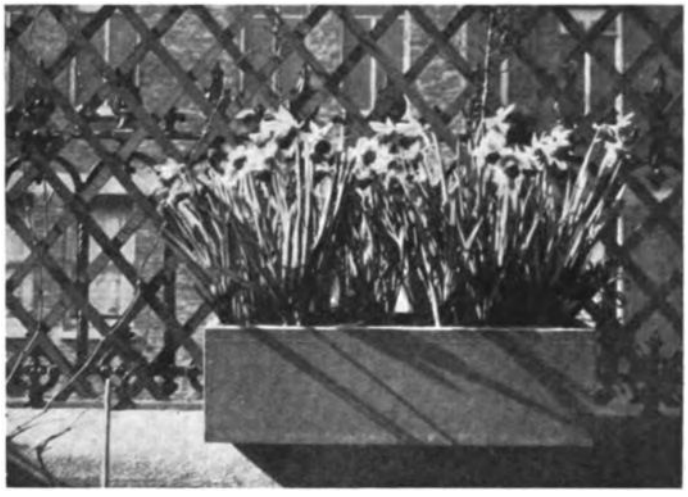
Among the flowering shrubs that can be relied on to succeed in town gardens, the deciduous kinds—*i.e.*, those which shed their leaves in winter—are in the majority. But there are a limited number of evergreen shrubs which will grow well, and will also produce blossom. Among these, Pieris japonica (illustrated) can be relied on to succeed if given the same treatment as that demanded by rhododendrons. That is to say, it prefers either a peaty soil or a light loam to which has been added a few decayed leaves. Lime should not be given to the soil prepared for these plants. Pieris is sometimes cut down by severe frosts, and it should therefore be grown in a sheltered position, preferably facing west.

Planting Evergreens.

April is the best month for planting new evergreens in the town garden. Planting must always be done with great care. There is inevitably a certain amount of damage done to roots when a shrub is moved. This temporarily deprives the plant of part of its water supply. Evergreens are particularly affected by this, as their leaves continue to give off moisture while the roots are unable to keep up the supply. For this reason, newly planted shrubs should be syringed daily unless the weather is showery, until they have established themselves. If this is done, and if the plants are put into prepared, deeply dug soil, and not planted too deeply or too shallow (use the nursery soil mark as a guide), they will speedily recover from the shock of removal.

Among evergreen shrubs particularly suited to town conditions the following is a useful selection: Golden aucuba, laurustinus, Euonymus japonicus, Fatsia japonica, Olearia Haastii, Pyracantha coccinea, Veronica Traversii, Ruscus aculeatus (Butcher's Broom). The last-named is specially useful for planting in dense shade where few other evergreens will thrive. The plants are mostly unisexual, and because it is seldom that plants of both sexes are grown, the fruits are not often seen. But when they do appear they are very ornamental and also interesting because of their curious position, growing in the "leaf" centre.

PIERIS JAPONICA, A FINE EVERGREEN FLOWERING SHRUB FOR THE TOWN GARDEN.



WINDOW BOXES NOW CONTAINING DAFFODILS SHOULD BE REFILLED THIS MONTH WITH SUMMER FLOWERING PLANTS.

After the Daffodils.

NODDING daffodils are in full flower in many a town window box this week. Our illustration shows a similar box, one of many that form a beautiful roof garden. It is now time for the cultivators to consider what plants they will use to follow the spring bulbs.

When the flowers have actually died down, it is best to lift the bulbs carefully, without injuring the roots, and to replant them in an odd corner of the garden. If no garden is available, they can be laid into a box, and their roots covered with a quantity of soil. Give a very little water occasionally until the tops are quite yellow, and then allow the bulbs to dry off completely. The empty window box should be thoroughly renovated before the summer planting is done. Turn out the old soil, see that the crocks or stones put in for drainage are replaced so that they are effective, and if repainting is needed, do this while there are no plants in the box, if you are not able to use entirely fresh soil, replace the old, but add a couple of handfuls of bone meal, mixing it well into the soil. A layer of leaves between the crocks and the soil will be a help in retaining moisture.

For a sunny window such plants as the following can be used: Canary creeper, tall nasturtiums, Cobæa scandens, and Morning Glory for the sides. These can be trained up over the window, trained up the window sides, or allowed to trail down the front. Geraniums, petunias, stocks, asters, snap dragons, sweet alyssum, lobelia and almost any of the fairly compact summer bedding plants are also useful in the sunny window box. For a shady box, auriculas, calceolarias, tobacco plants, fuchsias and violas are all suitable.

Syringing the leaves of the plants every evening during the warmer months is advisable. This not only keeps the leaves clean and healthy, but helps to counteract the excessive dryness of the atmosphere which nearly always affects pots and boxes that stand on sills where winds sweep past. One way of retaining moisture in the soil of the window box is by covering the surface of the soil with coconut fibre. This serves a double purpose, for it does away with the nuisance of rain splashing soil from the box on to the window panes. Watering the box is another duty which must be performed regularly. If once the box is allowed to become over-dry the soil cakes hard, leaving a space between it and the box sides. Water given when the soil is in this condition merely runs away down the sides without reaching the plant roots. One other point in connection with the renovation of the window box: Do not forget to raise it from the window sill. Wedge-shaped pieces of wood screwed to the bottom will do this satisfactorily. Boxes raised so that surplus water drains rapidly away are not harmful to the sills, and can be used without fear of damage.

Plants for a Windy Passage.

BETWEEN semi-detached houses, there is nearly always a passage in which it is difficult to cultivate plants. Sunshine is lacking, and often cold draughts sweep through making the culture of tender plants impossible. In such a situation I would suggest the use of tubs, painted green, and filled with fresh soil. Take care to put plenty of broken crocks or bricks at the bottom of each tub. Plant these with any of the following: Golden aucuba (Aucuba japonica), evergreen euonymus (Euonymus japonicus ovatus-aureus, E. radicans and its variety Silver Gem), funkia (ovata marginata), ivy, Solomon's seal and male ferns. A suitable rose for training on a fence in such a situation would be Félicité-et-Perpétue.

NOTES ON THE FLOWER GARDEN

The Alpine Edelweiss.

THE widespread but quite erroneous belief that edelweiss grows only in Switzerland, and that even there it grows only in its wild state, refusing to submit to cultivation, has been responsible for the exclusion of this interesting little plant from our rockeries. The variety so keenly sought after by tourists in the Alps is Leontopodium alpinum, a pretty plant with silver grey leaves and yellow flowers surrounded by a ring of silver grey bracts. This variety, given certain conditions, succeeds well in this country, seed being procurable from any of the well known firms of seedsmen. This should be sown under glass any time from March to May in boxes filled with sandy soil. When the plants are big enough to handle they should be potted up singly and placed in a sheltered place out of doors. By September they will be ready for transplanting to their permanent positions in the rockery or, if preferred, they may be kept in a cold frame during the winter and planted out in March or April.

Success or failure in the cultivation of edelweiss lies very largely in the preparation of the rockery. It must have a very sunny, sheltered exposure, and it is advisable to arrange the stones in such a way as to afford additional shelter to the little plants from cold winds. The most important factor of all, however, is drainage, which must be perfect. Unless this is attended to with the utmost care the plants will not survive, for damp is a much greater enemy to edelweiss than frost. It is always well, if at all possible to protect the plants from excessive rain by covering them with glass. Edelweiss blooms about a year after sowing. Although in the Alps it is perennial, it is best to treat it in this country as a biennial. It can, if desired, be grown successfully as a pot plant.—EDINA.

The Shasta or Ox-Eye Daisies.

UNDER the heading of Chrysanthemum maximum will be found several varieties of first rate border plants, but it should be borne in mind that they are all white and some of them bear a striking resemblance to each other. In spite of this, however, the giant shasta daisies ought to be represented in the borders by two or three kinds, and they should be planted at once to get the best results during the forthcoming summer. They are invaluable for cutting purposes, and the large single snowy white flowers are produced in quantity, so they are exceptionally showy in the garden and especially effective when grouped near more brilliant flowers, the contrast being most pleasing.

Mayfield Giant is a grand variety and is considered the finest and most prolific among the numerous forms of C. maximum, its large blooms, beautiful in shape, are produced on stout stems. This plant is at its best in mid-July. A little later flowering is Mrs. F. Daniels; while Autumn will prolong the flowering period till October. There are a few which have the effect of being more or less fringed, and the snow white Kenneth is characterised by the distinct laciniated petals, the variety Langford is somewhat similar, being most attractive and moreover a free and continuous bloomer.

These daisies will thrive in any ordinary soil, and may be had in bloom from June to October. For exhibition purposes they are ideal, and are also excellent for market work.—W. B.

Dwarf Conifers in the Rock Garden.

These can be Planted this Month.

THESE delightful little shrubs add greatly to the charm of the rockery be it large or small. They are quaint, interesting, and are always a source of interest to the visitor and owner alike. Easily grown, they require

A ROUNDED HUMMOCK OF PICEA EXCELSA GLOBOSA NANA.

no special treatment in the matter of soils or pruning, and need no winter protection; they appear to be immune from the effects of summer drought or winter's most intense cold. They play an important part during the winter in keeping the rockery "alive," and are for that purpose unsurpassed among rock plants.

When once planted and established, they should not, unless it is absolutely necessary, be again disturbed, as they do not transplant very successfully.

A FINE CLUMP OF THE SHASTA DAISY FLOURISHING IN A BORDER IN HALF SHADE.

Being of many forms and habits and differing in colour, the area of selection is a wide one, and plants may be had to suit all purposes. This list gives some idea of the varied characters of these charming little shrubs:

Thuya occidentalis Rheingold.—A little shrub of rare golden colouring.

Thuya occidentalis ericoides.—Heather-like foliage of a brown hue with glaucous tips, one of the best.

Picea excelsa globosa nana. — Prostrate growth which takes the shape of the stones over which it may grow.

Juniperus prostratus.—Flat-growing, foliage glaucous.

Cupressus obtusa pygmæa.—A quaint shrub.

Juniperus horizontalis.—Horizontal branching, glaucous foliage, brown stems.

Tsuga canadensis Sargentii.—A habit similar to that of a weeping willow.

Cupressus pisifera aurea.—A pendulous shrub of distinct form and colouring.—S. R. D.

A Fine Autumn-Flowering Shrub.

Caryopteris mastacanthus.

THIS is a distinct autumn-flowering shrub which forms a somewhat spreading bush from 3ft. to 6ft. high, but with judicious pruning it can be kept down to 2ft. or 3ft. where such a height is desirable. It has silvery green and scented leaves 1in. to 3ins. long, and the bright violet-blue flowers are produced in compact clusters in the axils of the upper parts of the shoots, the main or principal stem being useful for cutting purposes. It is a native of China, and was re-introduced to cultivation in 1880. Sometimes called the blue spiræa, it is a good subject for light warm soils where it can get every ray of sunshine, and in such a position it will thrive and put forth its pleasing blue flowers in September and October, a time when flowering shrubs are scarce. It is a suitable plant for the rock garden, especially if an elevated spot can be provided; while for the front of the shrubbery it is quite at home.

Although this pleasing shrub is hardy, it is liable to be killed back by sharp frosts if grown in a damp and shaded situation, but as a rule this only affects the last made growth. Even if this happens it is no real loss, because during March or April the previous year's shoots should be cut back to within an inch or so of their base. This treatment encourages strong growth, and keeps the plants within bounds. It is not at all difficult to propagate: if non-flowering shoots are made into cuttings during August and placed in sandy soil they will readily form roots, either in a little heat or a cold frame.—W.

The Californian Poppy Mallow.

THE Californian species of the poppy mallow (Callirhoe involucrata) is welcome in any rock garden where a prostrate plant of good colour is wanted. It is an attractive perennial with large crimson flowers, which continue to open for a very long period. Some seedling plants raised here (Thorpe Hall, Essex) last year commenced to bloom in June and made splendid colour until late in October.

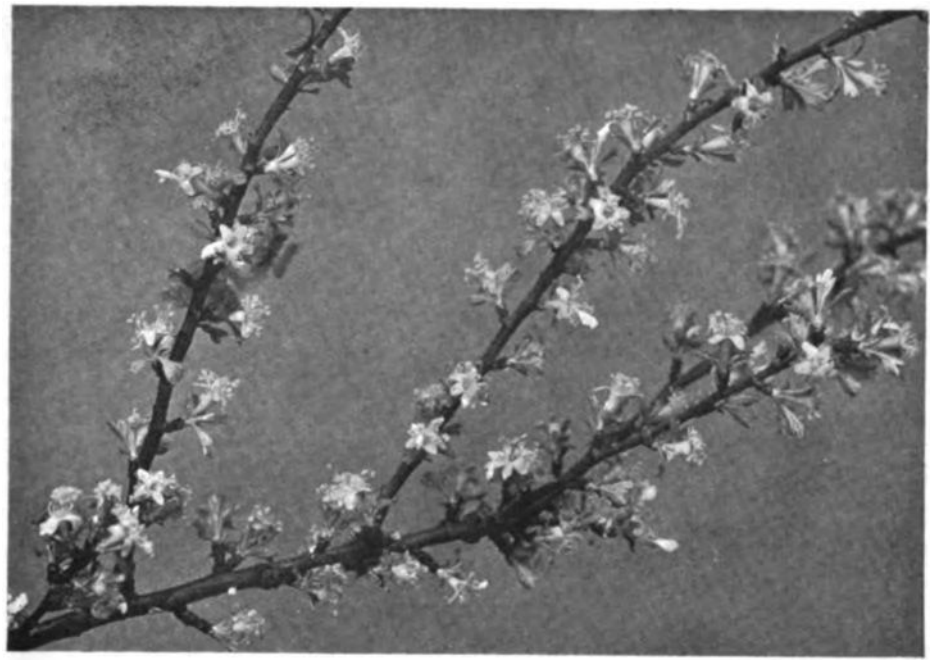
It should be planted in full sun, and seems to thrive in any soil. To be seen at its best this mallow should be planted where it can ramble over a large rock.

Digitized by Google

Callirhoe involucrata has proved to be of easy culture, and can be propagated by cuttings rooted in August or raised from seed sown in the spring. It is an excellent plant for any rock garden, both large or small.—R. MOORE.

An Attractive Gooseberry.

ONE of the most graceful and attractive gooseberries in cultivation in Western North America, is Ribes leptanthum. It usually flowers in most gardens during the last weeks of April, and the slender shrubs are richly covered, as may be well seen in the accompanying illustration, with white or pinkish flowers, standing one to three on a slender short stalk. The plant grows up to 5ft. or 6ft. The branches are smooth or bear short nodal spines up to almost an inch long. The leaves are broadly shield shape at the base, three or five cleft, with toothed lobes. They have a diameter from about ½in. to ¾in., and are smooth and hairy. They develop after the flowers, which are followed by lustrous black ovoid berries. This species was introduced into cultivation in 1893, but it is rarely met with in our gardens. It certainly deserves a place in the small garden on account of its pretty flowers, which are somewhat fragrant, but not so much so as in the closely related R. quercetorum from California, that is not quite so hardy and has distinctly yellowish flowers.—C.



THE SLENDER BRANCHES OF RIBES LEPTANTHUM STUDDED WITH ITS WHITE BLOSSOMS WHICH ARE TINGED WITH PINK.

An Interesting Japanese Cherry.

THE cherry of which the accompanying illustration shows a flowering branch has been quite a puzzle for the tree specialist. According to E. H. Wilson it is abundantly planted in Tokyo and Yokohama and also in other places in Japan. When, in 1901, the famous Japanese botanist, Matsumura, described it first as Prunus yedoensis, he regarded Oshima Island in Idsu province as its native home. When, however, Wilson made his investigations of the cherries of Japan, he found that the native cherry of this island is the wild form of P. Lannesiana, and he believes that P. yedoensis represents a hybrid between this wild form and P. subhirtella var. ascendens. It was introduced to the Arnold Arboretum in 1902, from whence it came to the then famous arboretum of Späth, near Berlin. Here the attention of the late Professor Koehne was called to it, who described it, in 1909, as P. paracerasus. When I published the part of my large handbook in 1906, containing the genus prunus, I had no good knowledge of Matsumura's plant. The last word on the origin of this cherry is not yet said, but Rehder in his new book on trees, seems to be of the same opinion as Wilson. But be it as it may, P. yedoensis is one of the finest Japanese cherries when in flower. It is perfectly hardy and grows well wherever I have found it. It deserves to be planted in every garden where there is sufficient space, in spite of its being apparently a rather short-lived tree. I have never met with a large specimen, but according to Wilson it becomes a tree up to 50ft. in height, with a broad flattened head from 50ft. to 60ft. in diameter. In April it is covered with masses of snowy white or somewhat pinkish flowers, which are slightly fragrant and appear shortly before or sometimes with the leaves in clusters of from two to six along the branchlets as the picture well shows. The small globose, shining black fruits are of no ornamental value. Wilson has described a form with pendulous branches, var. pendens, which has also been found in Japan.—C. S.

PRUNUS YEDOENSIS WITH ITS DECORATIVE FLOWER CLUSTERS.

Zinnias: Why They Sometimes Fail.

I HAVE met with people who have attempted to grow zinnias and through repeated failures have given up doing so. The mistake they made was not in the manner or time of sowing the seed, but in persisting in treating them exactly in the same way as ordinary half-hardy annuals. As a matter of fact, they were led away by their robust look and forgot that they are annuals which need to be nurtured and kept under glass until all fear of frost has passed away. No annual belies its looks more than the zinnia, and it is their apparent robustness which is their undoing. Rather wait until June in getting plants from cold frames to the open ground than run risks by planting them out in May, which is often a treacherous month on account of extremes of temperature, a state of things these tender annuals cannot stand.

Preparation of Ground.—Supposing it is intended that zinnias shall occupy a bed to themselves (a very satisfactory way of growing them to see them at their fullest advantage), then it is worth while to go to some trouble in its preparation. Should the soil be at all heavy, lighten it by the introduction of a little leaf-mould and sand, and incorporate with it some rotted manure. They will thrive in this. The position for them should be the sunniest one in the garden, and in getting the plants out of pans or boxes their roots should be disturbed as little as possible. A thin stick or cane will be needed for each plant, and this can be put out at the time. It will give them support in time of rough wind or rain, without which it is almost certain some of them will be bruised or broken, when it is remembered the stems of zinnias are hollow. They are plants which love heat, and do well on a south border other things being satisfactory. Seed sown in the warmth of a greenhouse any time now up to the end of April will, with the advantage of better weather conditions, not be far behind.—L. L.

SOME EFFECTIVE ORANGE FLOWERS

FLOWERS of orange colouring are exhilarating; they are cheerfully bright under leaden skies, and under the the influence of bright sunlight they do not "look hot," as do scarlet or red blossoms; while an additional merit is their ready and complete harmony with the majority of other colours. Especially well do they combine with blue and yellow flowers, and a vivid and most effective arrangement is a scarlet and orange border or bed.

Orange-hued blossoms of intense pure colour are not too plentiful, but a sufficiency of easily grown subjects are obtainable with which to create a very brilliant summer feature, and an old favourite, the pot marigold, or Calendula officinalis, comes readily to mind. It is difficult to imagine more intense coloration than that exhibited by the variety Prince of Orange, and the flowers are a perfect double form. Seeds may be sown at the end of March or early in April where the plants are required to flower, ultimately thinning the seedlings to 8ins. or 9ins.; or a stock may be raised in a greenhouse or frame and later transplanted; but the former method is, I think, preferable.

An orange zinnia of a reliable strain will create a fine display, and seeds may be raised in a little warmth and will well repay the trouble of being grown on in pots, using a rich but open soil. They must be thoroughly hardened preparatory to planting at the end of May or early in June. The seeds may be sown in late March or early April. Zinnia Haageana is infrequently grown, but is a quite good dwarf species with orange flowers of good colour.

A somewhat uncommon but very beautiful plant is Tithonia speciosa, somewhat zinnia-like in appearance and producing flowers of the most intense orange-scarlet; this half-hardy plant is easily raised from seeds and thrives in light soil. A Mexican annual, T. speciosa was introduced to cultivation so long ago as 1833.

Orange hollyhocks are not plentiful, and so Prince of Orange, offered by Messrs. Suttons, should receive a great welcome; it is of neat and comparatively dwarf habit, with flowers of the finest form, and is a good true stock.

Such antirrhinums as Orange King and Bonfire, perhaps not strictly orange, create a distinct and decidedly orange effect when massed, and they should most certainly be prominently featured where such an effect is desirable. Antirrhinums are hardly surpassed for garden effect, and the two varieties under notice are the best of a wide selection.

There are one or two pompon dahlias of fine orange hue, and for late summer and autumn effect they fulfil a useful purpose. This particular section has a dwarf, bushy and stiff growth as a strong recommendation.

Such lilies as croceum, umbellatum and its varieties, tigrinum in variety, Hansonii and Henryii will, naturally, occupy a prominent position or positions in an orange scheme. The species named behave, as a rule, very satisfactorily, and are not fastidious as to soil or position.

Gazania splendens is a particularly fine plant for a hot summer and will create a fine display in the forefront of a border or in a flower bed; except in favoured localities it is not hardy, but cuttings are easily procurable in the autumn and will winter in a cold frame or greenhouse. The flowers do not open in dull weather, but only the pessimist will foreshadow a prevalence of such conditions.

The day lilies (hemerocallis) are fine permanent subjects with orange flowers, and an additional inducement to plant them is the effectiveness of their grass-like foliage, a splendid foil to other plants; the blooms are somewhat ephemeral, but are successively produced. Trollius Orange Globe is a good June plant, very telling when massed.

It is scarcely possible to over-estimate the value and beauty of montbretias, of which a suitable selection would be Star of the East, Prometheus, George Davison and His Majesty; these delightful bulbous plants enjoy a well drained sandy loam and a sunny position. Planting can be carried out now.

In conclusion, I may accord brief notice to Alstrœmeria aurantiaca, fine for cutting; some of the orange or nearly orange Oriental poppies; Kniphofias of like colouring; and Senecio Clivorum.

I have treated the headline in a somewhat elastic manner, but all the plants mentioned are very near to orange in colour, and, judiciously used, all are capable of brilliant effect, pregnant with latent possibilities in the production of a variety of "harmonies and blendings."

R. A.

A BRILLIANT BORDER OF MONTBRETIA STAR OF THE EAST.

THE FUMIGATION OF GLASSHOUSES

FUMIGATION is essentially a chemical process and is the saturation of the atmosphere of an enclosed space with a toxic vapour. There are two classes of substances in use for the fumigation of glasshouses, *viz.*, those which depend on nicotine for their toxic properties, and those in which hydrocyanic acid gas is the killing agent.

The first essential for successful glasshouse fumigation is that the house must be airtight. All the cracks and crevices should be filled with paper or some other material and the keyholes of the door should be covered as well. The ventilators should be capable of being tightly closed and, if possible, should be so arranged that they can be opened from the outside after the fumigation has been given.

For nicotine fumigation, small heaps of tobacco shreds, say about a handful, are placed on the walks and side-walks at intervals of 10–15ft., and, starting at one end of the house, light the heaps, moving rapidly from one to the next, finally closing the door when the last heap has caught alight. The fumigation should be done in the evening, and the house should be fairly dry. Open the house early the next morning and allow the remaining fumes to escape.

As nicotine is not exceedingly poisonous except in large doses; its use can be fairly generally recommended against aphides, but it is not nearly so good a general fumigant as hydrocyanic acid gas.

By far the best fumigant for glasshouse purposes is one which depends for its toxic acid on the production of hydrocyanic acid gas. As hydrocyanic acid gas is very poisonous both to insects and to human beings, a great amount of care must be taken when using it, and the door of the glasshouse should be securely locked after fumigation.

In the past, fumigation by hydrocyanic acid gas was carried out by placing potassium or sodium cyanide in a porcelain dish and adding oil of vitriol to it. The gas was evolved by this chemical action, and the result was a high concentration of the gas for a short while. Of later years there has come on to the market a product called calcium cyanide, which in the presence of moisture only slowly evolves the gas. This gives a lower concentration of gas over a longer period, and, in addition to being much more easily handled, it is rather more efficacious than the older method. The killing agent is the same in both cases.

In order to know how much of this fumigant to use (too high an amount will cause severe

Digitized by Google

injury to the plants), it is necessary to find out the cubic capacity of the glass-house. The amount to be used is usually referred to in terms of ounces per 1,000 cubic feet. The cubic capacity of the house may be calculated in the following way :

For a lean-to, the measurements of length, breadth, height at back and height at the eaves should be taken. The average height of the house is then calculated by adding together the two heights of the house and dividing the sum in half. This average height should then be multiplied by the length and the breadth, and the result will be the cubic capacity of the house. For example, if the measurements of a house are 10ft. in length, 7ft. in breadth, 7ft. 6ins. in height at the back and 4ft. 6ins. in height at the eaves, the average height will be 6ft., and the capacity of the house will be 7ft. × 10ft. × 6ft. = 420 cubic ft. The cubic capacity of an equal span-roof house can be calculated in a similar way, by dealing with the house as if it were composed of two equal lean-to houses, with an imaginary back wall running down the middle of the house. In this case the two heights and length of the house are measured as before, but only half the breadth of the house is taken. From these measurements the cubic capacity of half the house can be estimated, and by doubling this figure the total capacity is thereby ascertained.

Having obtained the cubic capacity of the house the next thing to do is to remove from it plants which are liable to be injured by the fumigant. Asparagus plumosus, marguerites, sweet peas, antirrhinums, heliotrope and ageratum have been found to be injured by small doses of the fumigant and should be removed.

The house should not be watered for twenty-four hours before fumigation to ensure the foliage of the plants being dry. If the plants are in pots the side-walks may be damped down about two hours before scattering the calcium cyanide, as the presence of a certain amount of moisture is necessary to decompose the calcium cyanide and ensure the evolution of the gas.

The calcium cyanide is spread evenly over the walks about one hour after sunset. It is best to choose a still night for the fumigation as this precaution minimises the amount of gas lost by leakage.

The calcium cyanide should be in granular or powdered form and used at the rate of ½–¾oz. per 1,000 cubic ft. The house should be closed and locked. The temperature should be from 55°–70° Fahr., and it is better to have a rising temperature than a falling one, as a falling temperature would allow some of the moisture to condense on the surface of the plants. Several fumigations at intervals of from ten to twelve days may be necessary to rid the house completely of a pest, as the hydrocyanic acid gas does not kill the eggs and larvæ of insects effectively, and these hatch out afterwards, the adults being caught by the second, third, etc., fumigation. Ventilation after fumigation should take place early in the morning before the sun is too powerful.

The following insect pests may be successfully controlled by the use of calcium cyanide fumigant : Greenhouse white fly (adult), thrips (adults), aphides, mealy bugs and scale insects.

The following plants may be fumigated with the concentration given above without injury, provided always that precautions relative to temperature and moisture are observed : Azalea indica, begonia, carnation, chrysanthemum (not above ½oz.), cyclamen, freesia, fuchsia, geranium, gladiolus, marigold, palms and roses.

It is possible to use more than the amount stated with some of the above plants, and the grower should carefully note the effect of the dose on the plants and pests, and increase or decrease the amount accordingly.

H. D. BENNETT.

WHAT OUR READERS SAY

PIERIS FLORIBUNDA.

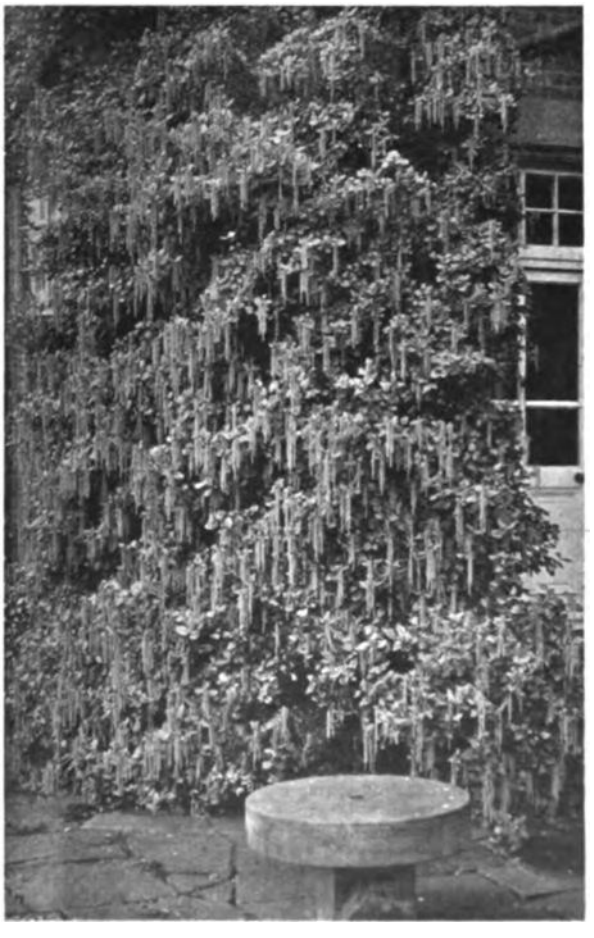
SIR,—That great gardener, Sir Herbert Maxwell in his book "Flowers" depreciates Pieris floribunda at the expense of P. japonica, and says plainly that P. floribunda is unworthy of cultivation where P. japonica can be grown. This, in my view, is unsound advice. Pieris japonica is, admittedly, a lovely species, beautiful alike in foliage and in flower, but it can no more take the place of P. floribunda than could Rhododendron Pink Pearl take that of Rh. Cynthia. Except that both species have white campanulate flowers, there is, in fact, little superficial resemblance. The upright spikes of P. floribunda often begin to expand their blossoms in October and November, and continue to do so, when the weather is not too severe, right through the winter. So far from discarding this shrub for any other species, I should myself include it in a list of shrubs for any small garden where ericaceous plants thrive.—V. G., *Warwick*.

A GOOD WINTER-FLOWERING WALL SHRUB.

SIR,—I have read with interest the note (February 26th issue) on "Garrya elliptica," and enclose a photograph of this excellent winter-flowering shrub which grows on my house wall. We are situated six miles east of Edinburgh, and so should not be considered to be in a warm climate!—C. M. COWAN, *Musselburgh, Midlothian*.

ROOTING CUTTINGS IN SAND.

SIR,—I was interested in the article by "W. F. R." (page 95) on rooting cuttings in sand, also the internode cuttings. For a number of years I have rooted marguerites in pure sand, placing them in boxes with a sheet of loose glass on top, and can usually rely on getting a 100 per cent. strike ; also, mine are established in pots before those struck in pots and soil are rooted. This year I have rooted all my chrysanthemums in sand with an average strike over all varieties of at least 95 per cent. ; this all happened by accident. On several occasions I have put "mum" cuttings in sand in pots and put in a covered frame with no particular success ; but late in November I was taking some plants into the dwelling-house with most excellent cuttings which would not have been of the slightest use when the plants came out again, so I just hacked them off, some below a node, some through a node and some halfway, and no leaves were trimmed off ; they were just pushed into the sand in a propagating case with no glass on the top, intending at the time to put them in properly, but they got overlooked for about ten days. When I pulled one out it was callused, so I let them alone, and every one rooted—about fourteen. Taking the lesson, I prepared boxes of clean pit sand and put in all my "mum" cuttings, with the above result. I should like to point out that *no* glass was put on top of them, and that boxes were used, *not* pots. As some sorts root more quickly than others, it is an easy matter to dig up the rooted ones first ; in fact, all mine were taken out three times before the lot were cleared off, and the longest only took just over three weeks, some only fifteen days.—W. P. W., *Stevenage*.



GARRYA ELLIPTICA DRAPING A HOUSE WALL.

SOME LOW-GROWING ROCK PLANTS.

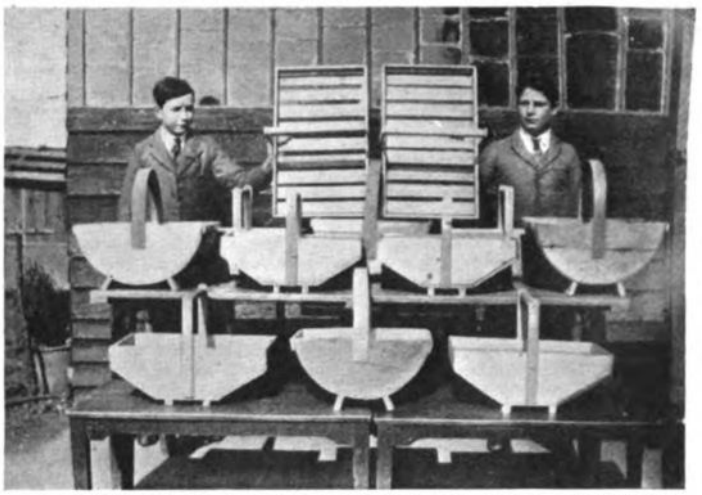
SIR,—Your correspondent, "G. J." (March 12th, page 178), asks for the names of some creeping or low-growing plants for a rockery. May I add the following (all of which I have found good in a situation such as he describes) to the list you give ? Mentha Requieni ; Veronica Teucrium Royal Blue, V. prostrata and V. incana ; Arenaria balearica ; Dryas octopetala ; Herniaria glabra ; Helxine Solierolii (this is an encroacher and will smother things with its pretty close green carpet unless checked) ; Dianthus neglectus ; the golden, silver and crimson flowered thymes ; Phlox reptans and P. subulata ; Hutchinsia alpina ; Hypericum reptans ; Draba aizoides ; Acæna microphylla and A. inermis ; Campanula garganica, C. pusilla and C. Portenschlagiana. "G. J." asks for the names of perennials only, but

Digitized by Google

may I suggest that he sows a few annuals to cover bare places during the first summer? He will find Ionopsidium acaule, Sedum cæruleum, Saxifraga cymbalana and Limnanthes Douglasii all suitable for the purpose. Campanula Loreyi (both purple and white varieties) is another pretty, although seldom seen, annual for a rockery, but this grows about 9ins. high. The purple-leaved Oxalis corniculata, although a perennial, will flower the first season, if sown early.—R. E. H., *Bath*.

MAKING GARDEN BASKETS.

SIR,—I wondered whether you would find the enclosed illustration suitable for publication. It illustrates some garden "trugs" made by boys of the Bethersden Council School Woodwork Class for use in the school gardens. They were constructed from instructions and diagrams contained in THE GARDEN a few weeks back. No difficulty was experienced in following out the details given in the article, and we now have a good supply of cheaply constructed serviceable trugs, including several made from cheese boxes given to us by a local grocer. Needless to say, I am an enthusiastic reader of THE GARDEN, and find its articles and attractive illustrations of great service in school.—C. W. MARTIN, *Headmaster*.



A COLLECTION OF GARDEN BASKETS MADE FROM DIRECTIONS GIVEN RECENTLY IN "THE GARDEN."

GENTIANA ACAULIS.

SIR,—I was much interested in your "Mersey Valley" correspondent's note on Gentiana acaulis, and wonder how far from a town and what kind of atmosphere your correspondent lives in.

I have grown G. acaulis for years in different aspects and in different soils, but on the few occasions it has flowered with me it has always been in the spring following a really good summer. I remember remarking to a friend that my gentian had five blooms the March after the good summer of 1921 and she told me that hers had fourteen and she knew of it blooming in other gardens that year. This makes me think that Mr. Farrer was right when he said that if you live near a town you will have difficulty in blooming G. acaulis.

I live eight miles from Manchester and three from Stockport, so the light is not as strong as it would be in purer air.

This makes me wonder if your correspondent lives higher up or in a less smoky district, as I am only three miles from the Mersey.—M. E. KENYON, *Cheadle Hulme, Cheshire*.

THE WINTER TREATMENT OF VERBENA CHAMÆDRIOIDES.

SIR,—In spite of its creeping habit, Verbena chamædrioides is one of the most striking of plants by reason of its rich scarlet flowers. It would be quite impossible to pass it by unnoticed. But, unfortunately, it is not generally found to be hardy, and unless cuttings are taken and protection given during the winter, it has hitherto been necessary to replace it every year.

Last winter the following method was tried and found to be most successful: In the autumn a number of cuttings were taken and struck in the sand frame. There is no difficulty in striking this plant, but, as with other things, the sand induces a very strong root growth. The rooted cuttings were potted up in rich compost and the pots sunk to the rim in the ground. They were given no protection whatever, and were in a very exposed, windswept situation. In spite of this every plant wintered well. The success of this method is possibly due to the encouragement given by the rich soil, the young plants being in such good heart that they withstood the prolonged damp and frost. The fact that the parent plants on the sunny slopes of the rock garden have all been killed rather strengthens this suggestion.

Next autumn it is proposed to plant the rooted cuttings direct into the rock garden in pockets prepared with rich soil for their reception. Hardy young plants so grown should flower weeks before those transplanted to flowering quarters in the spring. As this plant flowers continuously till the winter rains and fogs set in, it seems possible that it might be encouraged to become one of the longest blooming plants in our gardens.

Verbena chamædrioides planted in a dry wall with Zauschneria californica and big clumps of silvery foliaged, fringed white pinks in close proximity present an arresting picture, combining as they do an unusual contrast in colour, as well as in texture and form of foliage. The latter point is not given the consideration it deserves in garden planting for good all-the-year-round effect.—GWENDOLYN ANLEY, *Woking*.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

NUMEROUS reports have reached me regarding a scarcity of chrysanthemum cuttings over a very wide area of Scotland. Some varieties, it may be pointed out, have a better reputation than others in regard to the annual production of basal shoots. The members of the Massy family, for instance, are very free in that respect, while the representatives of the Thorp group are, as a rule, shy. Private gardeners who rely on nurserymen for their chrysanthemum plants in May should therefore place their orders early. Opinions vary as to the cause of the scarcity of cuttings. One view is that it is due to chrysanthemums being grown too long on the same soil, while another explanation is that in consequence of the early and severe frosts in autumn, many plants were nipped in the open, before the owners had time to put them under the protection of frame or greenhouse.

The problem of growing fifteen, twenty or twenty-five flower spikes of hyacinths in an ordinary bowl of fibre or 7in. pot is puzzling to the uninitiated, when they read the reports of our spring shows, yet it is all very simple. According to the modern method of cultivating tulips, hyacinths and daffodils for exhibition purposes, the bulbs are planted in layers one above the other and arranged so that the upper bulbs rest between those underneath. Sometimes as many as four layers of miniature hyacinths can be accommodated in a 7in. or 8in. pot. Tulip bulbs are comparatively small and lend themselves to this system, but daffodils of the trumpet sorts, such as King Alfred, Emperor and Tresserve, require 10in. or 12in. pots.

The formation of rockeries or stonework as distinguished from the more extensive rock garden, has been stimulated, in recent years, by the enterprise of Municipal Authorities in creating housing schemes and also by the speculative builder in erecting the popular bungalow type of residence. In both instances a small rockery frequently forms part of the general lay-out, but the owners are sometimes perplexed when it comes to the selection of suitable plants with which it is to be clothed. Many householders of these classes are in possession of a garden for the first time, while others, who have passed through the elementary stages, have little or no knowledge of alpines and rock plants, and are, therefore, in search of knowledge. With the object of helping them I have prepared the following list of hardy specimens and as cost is a consideration it may be stated that the fifty plants which are intended to form the genesis of a collection, can be purchased for 40s. or 45s. If that sum is beyond the average purse, then a selection may be made from the list and each plant may be estimated at an average of 9d. to 1s. each.

Achillea argentea; Æthionema Warley Rose; Alyssum saxatile; Androsace languinosa; Anemone Hepatica; Arenaria montana; Aster alpinus; Aubrietia (in variety); Campanulas pusilla, muralis, turbinata and pulloides; Cyclamen neapolitanum; Dianthus cæsius and D. neglectus; Dryas octopetala; Gentianas sino-ornata and Farreri; Geranium lancastriense; Helianthemum (in variety).; Hypericums polyphyllum and reptans; Iberis Little Gem or saxatilis; Iris cristata; Linaria alpina; Lithospermum prostratum; Œnothera missouriensis; Oxalis enneaphylla; Papaver alpinum; Phlox setacea (in variety); Potentilla Tonguei; Primulas Juliæ or Wanda, marginata and secundiflora; Ramondia pyrenaica; Saxifragas apiculata, Burseriana Gloria, Boydii alba, lingulata lantoscana, longifolia, pyramidalis, Bathoniensis, Wallacei and oppositifolia; Sedums spathulifolium and kamschaticum; Sempervivum arachnoideum; Silene Schafta; Veronica prostrata; Viola gracilis.

In addition bulbs may be planted, especially under the dwarfer growing plants to act as a carpet to the bulbs when in bloom, *viz.*:

Anemone blanda; Crocus Sieberi, C. Tomasinianus; C. versicolor and C. susianus for spring. Crocus speciosus and C. zonatus for autumn. Narcissus Bulbocodium conspicuus and citrinus; Iris reticulata; Scilla sibirica and S. bifolia; Tritelia uniflora; Eranthis hyemalis and E. cilicicus; Chionodoxa Luciliæ; Muscari in variety.

The present ideal spring weather has favoured operations in the garden. The temperature is high for the time of the year, as it is seldom that we experienced a range of 40° to 48° during the day in March.

ST. MUNGO.

THE FRUIT AND KITCHEN GARDEN

Scale and Black Aphides on Peach Trees under Glass.

BOTH pests are very destructive, the first-named, if allowed to increase freely, will cover the young fruits with excrescences which soon make them look unsightly and certainly interfere with the proper swelling of the skin. The black aphides cause the leaves to curl up—as they suck the juice from them—and then to shrivel and fall off. Syringing in this case is quite useless when once the aphides become established. I will first deal briefly with the scale. In the autumn trees infested may be cleaned; in fact, they should be thoroughly cleaned then. But however well the operation may be carried out at that time, odd scale may be found now owing to the great difficulty experienced in getting rid of the pest in one season. If a few old scale be left in the axils of branches or any small holes in the old stems, soon hundreds of minute scale will be found now on the last years shoots. At least several times each week the trees should be very closely examined and all scale seen destroyed by just touching them with any approved insecticide. A small brush is the best tool to use. In this way hordes of scale will be prevented from getting established on the trees this summer, and next autumn it may be possible practically to clear the branches. The best remedy for black aphis is fumigation. Do not wait until the black fly can be seen, but fumigate lightly once a week. If, however, aphides are found, fumigate on two successive evenings and then once a week. The trees should be dry and the borders moist at the time.—CHRISTCHURCH.

Two Useful Seed-Bed Levels.

THE two tools illustrated by Figs. 1 and 2 will be found most useful for making the surface of seed beds level and firm. Seed beds, such as for the growing of onions, need to be firm, and the tool illustrated by Fig. 1 and in detail Fig. 3 A, will be very suitable.

The seeds are sown in the usual way and then the bed is levelled up by lightly drawing the level (Fig. 1) over the surface, after which the bed is made firm by gently pressing with the same tool. A much better surface will be made in this manner than by the old method of treading with the feet.

A suitable size for the base is 12ins. square, and this is made of good wood, the bottom being made quite smooth by polishing with sandpaper. Any suitable shaft will do, and this must be made to drive into a slanting hole in the base, and made quite secure by means of a screw as shown in view A, Fig. 3.

The small tool shown by Fig. 2 is useful for using in the same way on small seed beds. A suitable size base is 8ins. square, and this is provided with a handle, details of which are given in view B, Fig. 3. The handle is of wood, the hand hole being easily cut out by means of a keyhole saw, and is fixed to the base by screws.

The tools should only be used when the ground surface is dry, in order to gain the best results.—W. J. S.

Temperatures in Fruit Houses.

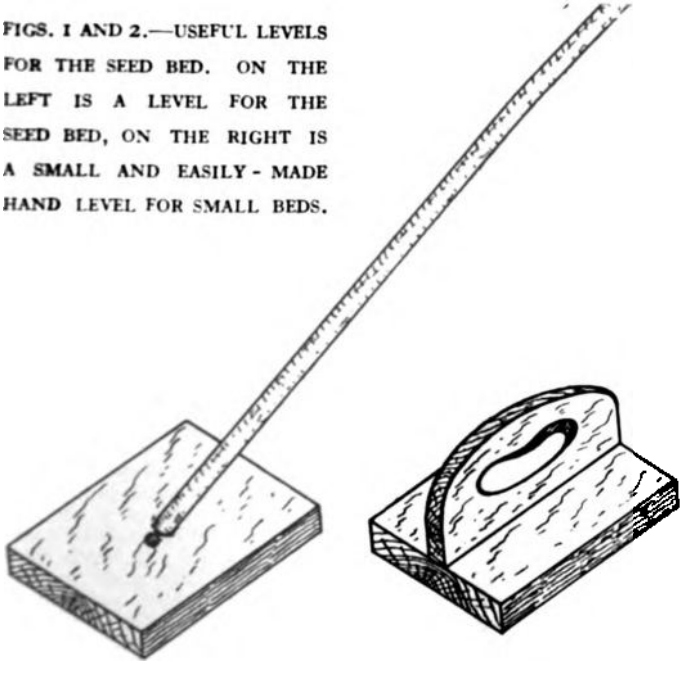
AT this season of the year the temperature in glasshouses rises or falls considerably in a few minutes, mainly owing to general weather conditions. Economy in artificial heating may be effected now if the cultivator is wise and husbands as much sun heat as possible. Heat from a furnace may be great in a fruit house and do more harm than good; whereas heat from the sun may be great and do more good than harm. Very often an inexperienced cultivator will keep up a sufficiently high temperature early in the day, not realising the fact that the sun, if it suddenly shines clearly on the structure, will cause the temperature to rise too high for the benefit of the fruit trees. To open ventilators rather wide to cause a drop in temperature also does harm, because the air at this season is often very cold, though the sun may shine brightly, and its rush into the house will chill and check the young growths and fruits. It is well to study the weather conditions very closely early in the morning and shut off artificial heat early, too, so that the necessary temperature may be obtained direct from the sun whenever this is possible. To lower a temperature suddenly is harmful; it should be reduced very gradually and when the heat, internally, is rather high, see that there is plenty of atmospheric moisture in the house, too, then the new growth will be healthy, though rather hard forced. Always begin early on bright mornings to ventilate and, if necessary, increase it gradually. Be equally watchful in the afternoon, when closing the ventilators, damping paths and borders judiciously, then healthy growth will result. Peaches require the lowest temperatures, vines a few degrees higher and melons the highest. At closing time the latter may be subjected to a temperature of 90 degrees from sun heat, mainly, if the atmosphere of the structure is kept moist.—G. G.

How to Grow Fine Parsley.

IN the first place it is necessary to sow seeds of a good strain. However good the cultivation may be, if a poor strain of plants be raised they will be extra coarse of leaf and practically useless. The finest curled varieties are vastly improved by good cultivation, except in some cases, where parsley will not succeed and it will not in certain soils. Where readers have experienced much trouble in growing parsley in their gardens, I advise them to sow some seeds in a box 6ins. deep and filled with fibrous loam, two-thirds and rotted leaf-soil, one-third. Place the box in a cold frame, or, failing a frame, cover it with loose squares of glass and shade from bright sunshine. Seedlings should appear in four weeks' time. Before they become too crowded, turn them out, soil as well, and transplant them carefully in rows, 6ins. apart and 12ins. from row to row. Water several times until they are established, then they will soon form fine specimens. Plant in deeply-dug soil. It is always advisable to sow seeds in several borders, wide apart, in the same garden when any difficulty is experienced in growing parsley freely in any given border. Furthermore, transplanted seedlings often form the finest plants. Overcrowding is always responsible for weaklings. —HANTS.

Early Spraying for Clean Fruit.

WHEN fruit trees awaken to activity at the call of spring, parasites of all kinds also resume a more active existence and begin their evil work upon the trees. This, then, is the time when spraying should commence



FIGS. 1 AND 2.—USEFUL LEVELS FOR THE SEED BED. ON THE LEFT IS A LEVEL FOR THE SEED BED, ON THE RIGHT IS A SMALL AND EASILY-MADE HAND LEVEL FOR SMALL BEDS.

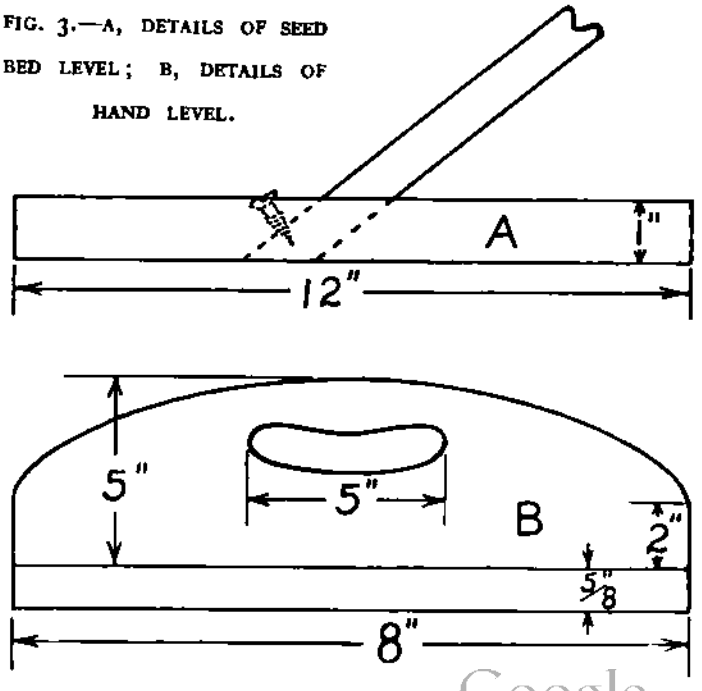


FIG. 3.—A, DETAILS OF SEED BED LEVEL; B, DETAILS OF HAND LEVEL.

Digitized by Google

to eradicate these pests, not merely because the trees are semi-bare, but because the pests are more easily dealt with and less numerous. Fruit growers realise that early spraying is a first guarantee of successful and satisfactory cropping, and the work is an essential part of the routine in all large and small orchards. First of all, we have fungus diseases such as scab, leaf blotch, mildew and the like; after living on the twigs all winter in a dormant state, these spring into active life now and creep over the new leaves and shoots. Then we have sucking insects like the aphides, American blight and so on, which pierce the soft tissues of the tree and suck sap therefrom, crippling growth and so reducing the chances of a good crop. Again, there are the leaf-eating maggots and caterpillars—those which attack the flower beds and, finally, those which eat into the fruits, like the larvæ of the codlin moth and the sawfly.

It is, of course, essential that the grower should gain some idea of the pest which is doing the damage; then he can act against it in the most efficient way. Against fungi one may use Bordeaux mixture or lime sulphur, the latter being advisable when the tree under question is liable to suffer from the spray. Against sucking insects, a "contact" insecticide is employed; the newest and most efficient substance to use is nicotine, diluted as directed when the concentrate is purchased. Leaf-eating caterpillars are killed by using something which poisons their food, like arsenate of lead; 2 oz. are stirred into 3 gallons of water and a fine spray is applied so as to coat every part of the tree with the poison. It is useful to note, too, that nicotine and lime sulphur may be used together, or nicotine and arsenate of lead. One spraying with any one wash is not sufficient for many reasons. Briefly, I may state that the safest plan is to spray three times: first when the buds are as yet unopened, second when the petals have fallen, and third some three weeks later. Spray on a calm day, the best time being in the evening; apply the wash so that every portion of the tree or bush is thoroughly wetted, but do not spray when the flowers are open and awaiting fertilisation by bees.—CLYDESDALE.

April Strawberry Planting.

STRAWBERRY plantations may be made in northern districts in April. A crop of fruit cannot be obtained this season from an April planting, but the plants will be well developed before next season, and the plot can be intercropped this year with cabbages, sprouts, lettuce, onion plants, etc. The strawberry rows may be 24ins. to 30ins. and the plants in the rows 15ins. to 18ins. apart. The rows can be either flat or in the form of a low ridge. Some of the best runners this season may be layered or potted for planting in the autumn, or to fill up any vacancies next spring. A good tip was that of a gardener who, having obtained a few choice plants and, wishing to make the most of them, planted them on a plot at double the usual distance apart. From the best of the next season's runners he got quite as many good plants as was required to complete the plantation. He intercropped the plot with shallots and onion sets.—JOHN WIGHT.

Fruit Garden Notes.

A JUDICIOUS thinning of fruit-buds if they have set too thickly is advisable at this season. This job ought to be done early to be very effective. Fruit blossom may also be thinned out. It often happens that the one flower is injured by the other when too close together. Newly-planted trees and bushes will require some sort of mulching, and also an occasional soaking with water or weak liquid manure if there is a spell of drought. Fruit trees may be grafted during mild, soft weather.

Round and Wrinkled Seeded Peas.

EVERY gardener who grows peas should study varieties and soils closely. A very fine pea is seen, probably, at a show, and so this particular variety must be grown in the future, irrespective of soils. Where a sandy loam obtains, the wrinkled marrowfat peas will thrive generally early in the year—the pea season. But if an attempt is made to grow them in a cold, clayey soil, failure will result in most cases. It is certainly advisable to grow only the round-seeded sorts in such retentive soils for early use and, also, for the latest crops, as in late summer almost the same soil conditions obtain as in the spring. The only difference is in the temperature of the soil—it is warmer in the early autumn. The atmosphere is moister, the temperature gradually gets colder, and then the marrowfat peas become mildewed and the pods do not fill. Here we find the naturally early, round-seeded sorts much the best; their pods may be small, but they fill, and the peas in them are sound. So, before sowing the pea seeds indiscriminately map out the season, as it were, and thus reap the highest yield from each variety. To assist the growth of marrowfat varieties in heavy soils, even when the seeds are sown in June, it is advisable to use some drier, finer and lighter soil as a mere covering of the seeds before the ordinary heavy garden loam is put on.—G. G.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

At the Bottom of the Garden.

Instead of the narrow border which ran along the hedge at the end of our suburban garden and which was too shady to grow many flowers, we have built a low dry wall of the large, hollow, concrete blocks which are being used locally for building. These can be bought fairly cheaply and are quickly placed in position, a row only one block deep making a pretty edging to the formerly uninteresting border. In the centre a gap 3ft. wide has been left, and the blocks built up on either side to form ascending steps, one block deep in front, three at the back. Between the two top blocks behind a plain seat is fixed. The blocks are planted—both in their hollow interiors and in the cracks between adjacent blocks—with aubrietia, golden alyssum, thyme, lithospermum, pinks, arabis, saxifrages and sedums. The result is extremely pleasing.—J. M. H.

About Pergolas.

Wood posts always decay where they emerge from ground, even if creosoted, etc. To preserve indefinitely, cut sheet lead 8ins. wide, long enough to encircle post and overlap 1in.; along one edge of lead smear "Ferotax" (or other plastic preparation for repairing leaky roofs) 1in. wide. Wrap lead round post with "Ferotax" edge upwards and inwards and 4ins. above the ground. Use copper nails round top edge and overlap. Hammer edges close to wood. New posts: Sink in ground 9ins. old drain-pipes, top edge 6ins. below surface. Place post down centre of pipe and fill in cement, trowelling to a cone from top of pipe upwards and inwards to post. The lower edge of lead band should overlap this cement cone. I have a pergola twenty-five years old, built in wood in this way, and not touched in the meantime and quite perfect now.—G. M.

Humus for Shallow Chalk Soil.

Each year, in early spring, I sow, very thinly, a few rows of cress, which is allowed to run to seed (I generally harvest about half a gallon of seed). Between such crops as potatoes, peas, beans, and in any vacant space as crops are cleared, I sow cress. This grows very rapidly (while young it may be used as salad), and when 4ins. or 5ins. high is dug in. The result is very beneficial. The greenstuff quickly decays and adds considerably to the "holding power" of my shallow chalk soil.—E. S.

Celery Fly.

My experience with this pest is that the trouble begins when air is being admitted after the seedlings have been established in the frames. Last season, instead of dusting the little plants with soot, which is soon washed off when they are watered, I put a teaspoonful of chloride of lime in the front of the frame on a piece of slate, and the result was I had a perfectly clean batch of plants to put out. (The frame must not be closed entirely afterwards.) With dustings of soot occasionally during the season, the whole of my crop was kept practically clean, and I have been digging this winter and spring—W. J.

Seed Guards.

Simple but quite effective seed guards may be made by using willow twigs. These are bent to form a hoop and the ends stuck in the ground at the ends of the rows. Black cotton may be rapidly passed from one to the other along the row.—H. B.

Slugs and Chrysanthemums.

Slugs have a great liking for young chrysanthemum shoots, and not infrequently make destructive attacks upon them even before they appear above ground. When the old stools are laid in and the cuttings are slow or weakly, slug trouble may be suspected. In a 2-gallon can of water put half a teaspoonful of permanganate of potash and half a teaspoonful of salt. Use this to water over the plants. It will do the chrysanthemums no harm; it will not even kill the slugs, but it brings them to the surface in a few seconds, and they can then be collected and despatched.—H. D.

How to Use a Garden Line.

A garden line incorrectly fixed leads to the making of crooked drills of uneven depth, and these can be avoided by taking a few simple precautions. First, set the free peg of the line very firmly and leaning slightly back from the direction of the bed. Then walk across the bed, unwinding the line and at the same time break down clods or push on one side with the feet any stones in the course of the intended drill. Arrived at the other side of the bed, pull the line tightly, loop it once or twice round the peg which passes through the reel and then push peg hard into the ground with a slight backward tilt. In the case of a long bed there is a tendency for the line to move, and this can be prevented by sliding one foot backwards on the line while cutting out the drill.—W. H.

Carters Tested Seeds for Garden and Lawn.

LOOK TO YOUR LAWNS

ALL lawns should be re-conditioned immediately if the turf and surface are to be in good condition for the coming season, consequently, preparations should be made in advance, and all the required materials—Grass Seed, Fertiliser, Worm Killer, etc., assembled. For particulars how to renovate your lawn, make a new lawn, etc., write to-day for Carters illustrated Booklet on Lawns, post free on application.

ANNUALS

Seeds of these very popular and easily grown flowers shou'd be sown without delay to ensure a brilliant display throughout the Summer months.

In order to assist customers we have prepared an interesting booklet "Annua's to Sow Now," and we shall be pleased to send a copy post free to any address.

THE GARDEN

VOL. XCI.—No. 2888. APRIL 9, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Easter Flowers at the Wisley Gardens.

DURING the last few days of brighter weather many plants are now adding to the general interest of the gardens. This, naturally, is the season of the early alpines and, apart from the new alpine house, which is gay with pots and pans of numerous saxifrages and primulas, plants on the rock garden are beginning to show fine masses of colour. In the wild garden and on grass banks in the surroundings charming groups of the dainty Narcissus cyclamineus that have seeded and naturalised in the damp moss are most attractive. Among shrubs in the woodland is Pieris japonica with its large clusters of drooping white flowers giving the whole plant a lace-like effect. Rhododendron præcox has so far escaped frost, and is a plant worth planting more extensively even if we do not enjoy the flowers every year. Camellias are beginning to open their flower-buds. It is indeed strange that these handsome flowering evergreen shrubs are not more freely planted in the open, as they are quite hardy.

The new shrub garden beyond the woodland containing the large collection of heaths is always of interest. There are some varieties in flower practically every month of the year.

Forsythias and prunus in many varieties also contribute to the interest of this part of the garden at this date. Prunus Pissardi Woodii with its pink buds and deep-coloured foliage should be made a note of as one of the best. Cornus Mas, although an old plant, is not to be despised at this time when covered with its yellow flowers, so conspicuous on the leafless wood. A plant that makes its presence known by its fine fragrance rather than by its multitude of small yellow flowers is Azara microphylla. In the trial of daffodils, in which over a hundred varieties are represented, many are now in bloom, although the earlier varieties are ten days later this year.

AN EASTER GARDEN PICTURE.
Daffodils in drifts in the woodland. These can be now seen in all their spring beauty in the woods and in our parks and gardens.

Our Photographic Competition.

WITH the increasing popularity of gardening there has grown up alongside an intense interest in garden photography and it is with a view to encouraging this mushroom growth still further, that we propose running a photographic competition among our readers during the coming summer season. This competition will commence next month with our issue of May 7th, and will continue through the summer months, when the garden display is at its best. Readers are invited to send in photographs illustrating some aspect of their own garden, a picture of a border, an attractive bed, or clump of a particularly fine herbaceous plant, a group of shrubs, a portion of the rock garden or a collection of plants in their greenhouse. There are any number of garden pictures which may be made and all of them of interest.

In order to assist readers as much as possible and those who have not before attempted to take garden or flower photographs, we publish in this issue the first of two articles on the use of a camera in the garden, giving helpful hints on the taking of garden photographs and we hope that they will prove of some use to those who are keen photographers as well as keen amateur gardeners.

Many of these garden pictures, apart from their sentimental value in recalling to mind pictures of the garden at different seasons of the year, have much to teach. They may suggest ideas to others of how to arrange a border or group shrubs or how to obtain the most effective display in a small space. Photographs undoubtedly have a definite teaching value and we hope by this competition to bring together the ideas of many of our readers and make them available to all. Full particulars, giving the rules governing the competition and the prizes will be given in our forthcoming issues. This early announcement, we hope, will encourage amateurs to get out their cameras for Easter and take a few pictures of their own garden to send along for our competition.

This Week's Work

For Gardens in the South and Midlands.

Plant out gladioli in prepared beds.
Sow hardy annuals in the open ground.
Plant border carnations and Allwoodii pinks.
Prepare ground for planting evergreen shrubs.
Spray fruit trees with lead arsenate wash in order to keep down attacks of insect pests.
Prune all bush roses except tea varieties.
Plant out autumn-sown sweet peas and stake the young plants at once.
Make succession sowings of onions, carrots, cauliflowers, cabbages, parsnips, dwarf beans, beet, etc.
Transplant celery seedlings.

This Week's Work

For Gardens in Scotland and the North.

Prune bedding roses of the H.T. and H.P. types.
Top-dress the beds with old manure and fork in carefully.
Sow sweet peas in shallow drills in the open ground.
Transplant pansies, violas and calceolarias raised from cuttings.
Make a sowing of onions, leek, carrot (short horn), peas, parsley and lettuce.
Sow a pinch of Early Milan or Golden Ball turnip for early summer use.
Plant sweet williams, Canterbury bells and aquilegia.
Prick out half-hardy annuals into other boxes.

Digitized by Google

THE UPKEEP OF A LAWN

THE actual construction of a lawn must be so well understood by now that it can no longer contain any mysteries and, as a limit has been placed on the length of this article, I intend practically to concentrate on weeds.

If there were no weeds, or if they could be killed easily, all lawns would be more or less perfect; but, alas! there are many weeds, and they are such stout fellows that they cannot be killed easily unless one takes the trouble to study them, and then it is more or less a simple matter to convert a mass of weeds into a perfect grass lawn in a year or less.

Weeds may roughly be divided into three classes: Surface rooters like daisies, Prunella vulgaris or self-heal, chickweed, pearlwort, creeping buttercup, moss, yarrow, clover and others. Weeds that root to a medium depth, of which the plantain family is by far and away the worst. The common plantain is very difficult because, although

A LAWN PARTLY TREATED WITH "CARTERITE," AND WITH PART UNTREATED.

it naturally grows erect, it can adapt itself to the mowing machine by keeping its leaves and seed heads so close to the ground that it not only escapes injury but it can produce and ripen seed in abundance, and is thus able to colonise large areas with extraordinary rapidity. The rapid spread of the plant is particularly noticeable in turf used for vigorous games, the seeds being spread all over the ground by the feet of the players. Apart from this the common plantain loses its foliage when the frosts set in, and so, by invisibility, enjoys protection from the autumn until the spring.

The third class is chiefly represented by dandelions and other deep-rooting weeds that can adapt themselves to a new habit of growth.

Many regard the common dock as a noxious weed, and so it is in fields and pastures, but as it cannot alter its growth from an erect to a prostrate form, like the dandelion, it cannot long survive being regularly denuded of its foliage by the lawn mower.

Mass Treatment.

Should a lawn contain so many weeds of all sorts that it is impossible to treat them separately, it should be given a broadcast dressing of "Carterite" or lawn sand at the rate of 4, 6 or 8 oz. to the square yard, according to the nature of the soil and the number of the weeds.

For light soils use about 4 oz. to the square yard, medium soils 6 oz. and heavy soils 8 oz. The lawn sand, being highly caustic, will burn everything, including the grass, temporarily, and will kill at least 80 per cent. of the weeds, only the very strong and deep-rooting varieties escaping.

Turf so treated will look like nothing on earth for a week or two, but about fourteen days after the treatment the lawn sand will lose its caustic properties and then, functioning as a fertiliser, will stimulate the grass to such an extraordinary extent that in many cases the turf will heal and close up without any help. In other cases, particularly if the turf is weak and the soil light, it may require renovating, but this will be discussed later.

The Spot Treatment of Daisies and Other Surface-Rooting Weeds.

Divide up the lawn into strips about a yard wide by means of pegs and strings. Give the worker a distributor, which is a conical tin with a lid at the larger end at which it is filled, the smaller end having an opening three-eighths of an inch in diameter. Fill the tin with lawn sand and allow it to escape by removing the first finger of the right hand, which should be placed over the opening while filling, for such a time as to allow, say, a saltspoonful to fall on a small weed and so on, or fill a pail and apply the lawn sand by hand. Lawn sand can be used at any time of the year provided that the weather is fairly dry and it is actually used on a dry day.

Spot Treatment of Plantains and Other Weeds of a Similar Nature.

These can be killed with lawn sand in the same way as explained above, but as they are more tenacious of life, give them a stronger dose and be prepared to give any that survive, as some are sure to, particularly should damp weather set in soon after treatment, a second dose.

Another way is to use "Plantainkil," a very powerful chemical combination, devised solely for the spot treatment of strong-growing weeds, such as the common plantain, but it must not on any account be used broadcast. "Plantainkil" should be used between April and September on dry days and during dry weather; in fact, the weather cannot be too dry or too hot.

Dandelions.

Large weeds with long tap roots, such as the dandelions, can be very easily destroyed without any irksome backaching labour by the use of a strong liquid weedkiller ejected on them by the use of a weedkiller ejector. All one has to do is to prepare the weedkiller at double strength and fill the ejector. Then walk slowly over the lawn and squirt a little of the weedkiller on each by just pressing the plunger with the thumb. The weeds will wither within a day or so, and within a week will be dead from end to end. Nothing can be easier than this, because it calls for little or no effort, stooping or skill.

Clover and Large Patches of Creeping Weeds.

Clover is regarded as one of the most difficult weeds to deal with, chiefly because it grows in such large patches in what may otherwise be a good turf, that many hesitate to face the temporary disfigurement of the lawn entailed by its destruction. It can, however, be discouraged and in many cases eliminated without even temporarily disfiguring the turf by the use of Anti-Clover Grass Fertiliser on the "little and often" principle at the rate of 1 oz. to the square yard. The fertiliser should, of course, be mixed with three or four times its own bulk of dry sand, sifted soil or fine ashes so as to increase its bulk and so make an even application possible, allowing an interval of two or three weeks between each dressing and watering in if necessary.

Another and more certain way is to dress the patches with lawn sand at the rate of 2 to 4 oz. to the square yard. This method will obviously disfigure the lawn temporarily, but is it not worth it? "Carterite" will kill patches of clover, yarrow, pearlwort, daisies, self-heal, moss, creeping buttercup and, in fact, any creeping weed, and if one is prepared to face the temporary disfigurement of the turf, and, if necessary, go over strong patches more than once and, finally, after an interval of about a week, rake and sow with grass seeds, it is the easiest and best way of dealing with this class of weed, the alternative being to cut out the patches and repair with clean turf.

Weed Study.

One cannot expect to be successful at anything unless a certain amount of thought and study is given to the subject, and this applies to weeding as much as it does to anything else. Some weeds, such as the common plantain and dandelion, lose their foliage in the autumn and are quite invisible until the spring. Daisies and most of the other creeping weeds retain theirs all the year round.

When one is faced with weeding a lawn, no matter how large it may be, do not say it is impossible, because it is not, but just try out what appears to be the best method on a measured plot and see how it works and how long it takes. It will then be an easy matter to calculate how long it will take to weed the whole area. Various preparations act differently on different soils and weather conditions, so the only way to get good results is to try their action and effect on a small scale at varying rates.

The most hopeless turf in the world can be cleaned, worked up and made perfect in a year or less if the will to win is present and the following system observed:

1. Broadcast "Carterite" with a heavy hand, giving an extra dose to any large, strong, stubborn patches of weed.
2. Kill the dandelions and other large weeds by ejecting a strong liquid weedkiller on them.
3. Spot treat the survivors.

Renovation.

About seven days after the final application and all or most of the weeds are killed, rake the bare and thin places and sow with grass seeds at the rate of 1 oz. to the square yard, sowing the seed thinly where the turf is fair to good and thickly where it is thin or bad. Rake again in order to cover the seed, or if sufficient fine soil or compost is available, top dress at the rate of one load to 150 square yards before the final raking, and finish off with a light roller. REGINALD BEALE.

A CAMERA IN THE GARDEN

EVERY gardener ought to own and use a camera. For photography very happily overcomes the one and only drawback to gardening—the fleeting nature of its triumphs.

Photographs do *not* fade, and a good series is a continual source of instruction as well as a pleasant reminder of one's triumphs. We all know the value of a gardening diary, if illustrated with photographs its value and interest will be vastly increased.

It is true that many photographs taken in gardens are neither interesting nor beautiful, but it is quite easy to obtain results which are both.

I will keep to practical matters as closely as possible, but it is necessary to point out first why so many flower photographs are unsatisfactory. The chief reason is that ordinary films and plates are colour-blind.

They are very sensitive indeed to blue light, almost insensitive to green and yellow, and quite insensitive to red. So a blue flower photographs as white, green foliage as dark grey, yellow flowers as almost black, and red blossoms as dead black. Obviously, these results can never satisfy anyone who knows the subjects.

Luckily, though the fault is a serious one, the cure is easy. It is simply to use a colour filter (a yellow glass) over the lens. This holds back the blue light and enables the green and yellow to have their proper effect and correct renderings are therefore obtained. This increases the necessary exposure by about eight times, but as all garden pictures should be taken with the camera fixed on a tripod, this is no drawback. Time-exposures can be given instead of snapshots, an advantage in every way.

Just a word as to apparatus, and then we will get to practical business. For general garden pictures, views of borders, etc., any ordinary hand camera will do. A great deal can be done with such a camera in taking single plants, individual blooms and vases of cut flowers; but for this work a camera fitted with a focussing screen has advantages. If you are getting one specially for flower photography, let it be a quarter-plate hand-stand camera with focussing screen, dark slides, long bellows extension and a long focus lens—say a 7in. lens.

With a camera, a tripod and a colour filter, we are now ready to start photographing. Let our first subject be a general view of the garden.

THIS PHOTOGRAPH WAS TAKEN AT MID-DAY, AND SHOWS LITTLE LIGHT AND SHADE. SHADOWS WOULD HAVE IMPROVED IT.

THE USE OF A COLOUR FILTER HAS BROUGHT OUT THE SHADOWS AND THE FLOWER DETAILS.

The choice of view-point is important, and you must keep in mind that your pictures will be in monochrome, *not* in colour. So the lines and masses into which the scene falls are more important than the colour contrasts it shows.

As a rule, your foreground should be *open*. A stretch of grass, a wide paved walk, or even a path. This gives an impression of spaciousness. Choose your view-point so that paths lead into the picture, not out of it; and avoid the symmetrical—unless your subject is a formal garden—by setting up your camera rather to one side of the lawn or walk rather than in the centre. These may seem small points, but they make a vast difference to the result.

Never take a border square on: take it at an angle—and, whenever possible, show a little of the lawn or path that edges it. This gives a *foundation* for your picture to rest on.

Rock gardens are usually unimpressive in photographs because the camera is held too high, looking down on them. The result is that they appear squat and flattened. By lowering the camera you, apparently, raise the rocks, etc., until, by taking your view from within a foot or so of the ground, even stumpy little rocks become impressive.

Do not take your garden pictures at midday when the sun is right overhead. Early morning or late afternoon, with the long shadows they provide, give much better results. Whenever possible, do not face the sun *or* have it directly behind you—it should be rather to one side or the other

The colour filter will ensure a good rendering of the play of light and shade and a proper rendering of the vivid green of grass and foliage.

Using a colour filter and ordinary roll film or plates, an exposure of round about 1sec. with the lens set at F 16 or US 16 will be *about* right. Conditions and light vary so much that no more definite advice can be given. A. G. W.

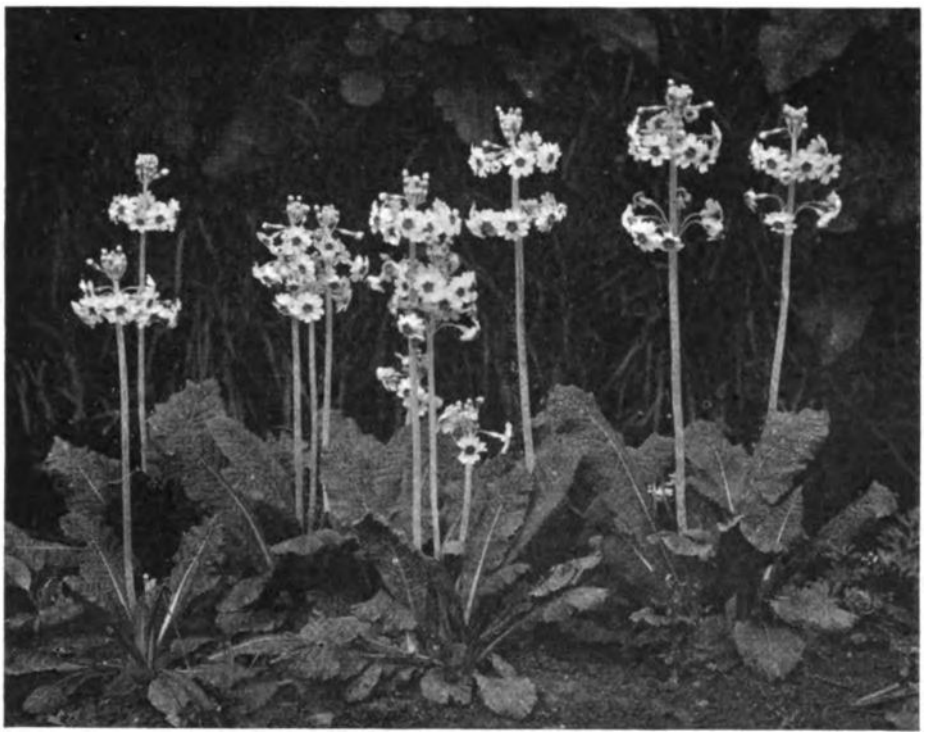
PRIMULAS OF EASY CULTURE

In this article is given a selection of species and hybrid primulas which the amateur should try in his garden, together with notes on how to succeed with their culture. They are all beautiful plants and easy to grow, provided they are given the conditions they like.

WITH the discovery of so many new species of primula in recent years, this genus has grown into an enormous family.

I only propose dealing with those species and hybrids that are of easy cultivation, that will give a good show of bloom and are easily propagated. Most of the primulas enjoy an abundance of moisture in the growing season and many species in ideal conditions grow into huge plants, throwing up many stems, and in the case of the candelabra section these develop whorl upon whorl of bloom, growing to a height of 4ft. and more. But though they enjoy moist conditions, it must not be imagined that they cannot be grown without water. I have grown many thousands of these primulas without any natural water other than rain, and most gardens should be able to provide suitable positions, large or small, where these can be grown successfully.



THE ROSE PINK P. PULVERULENTA LADY THURSBY FLOURISHING IN SEMI-SHADE.

As primulas seem to prefer cool, moist conditions at the roots, I suggest planting them where they do not get full sun and therefore do not get dried out. The ground should be dug deep to allow a good root run and they will soon get down to moister and cooler conditions. In places where there is water, it is, in my opinion, essential that there should be drainage of some sort, unless, of course, it is running water. They resent stagnation.

Where to Plant.

A north border—the north side of a wall—or a shady cool spot where the trees shade the plants, but do not rob them of moisture, should provide suitable positions for these primulas. Many cool, damp spots in the rock garden can be found, but do not pitch them up high and dry in a sunny pocket.

If the garden is on gravel or chalk, I think it would be difficult to grow these primulas, unless special preparations were made. Where space permits these primulas should be grown in masses, allowing them to sow themselves, for they never look better than when growing massed.

Raising from Seed.

They are all easily raised from seed, or increased by division. I prefer to sow seed as soon as ripe and germination will be quick, but if left till the spring it will take longer, for the older the seed the longer it will take to germinate. When sown it should never be allowed to get dry. The seedlings can be wintered in a cold frame and in the spring, as soon as they can be handled, they should be pricked off into boxes and grown on until large enough to plant out. This should be done as soon as possible, to allow the plants as long a growing season as they can get and by the autumn they should be real strong plants that will flower the following spring. If they are increased by division, I prefer doing this either in the early autumn or early spring. In the former case, sufficiently early to let the divisions make new roots and get well established by the time the cold weather comes and in the latter as soon as the weather and ground are warm enough to create root action. Should they be planted under or near trees, I always like to rake off dead leaves and leave them fully exposed; this makes them quite hardy.

In the case of species they can be raised from seed, but in the case of hybrids they must be increased by division, if any particular plant is required as seed will not come true.

The following belong to the candelabra section:

P. japonica is one of the oldest and best known. The type is of rather a crude magenta shade; there are several other colours and in growing "P. japonica, mixed colours" it is wise to select and save seed from the best colours, discarding the bad ones. One of the best is Etna, a red, and Millais' Scarlet, which is a good clear colour.

P. Beesiana.—Later flowering, rather reddish purple, with a slightly mealy stem.

P. Bulleyana.—Like Beesiana, later flowering, with orange yellow flowers. This species is apt to throw narrow petalled flowers, unless the strain is kept up to the mark.

P. Athlone Seedlings.—This is the name by which I have always known the hybrids between P. Beesiana and P. Bulleyana, a delightful strain which includes shades of pink, carmine, rose, mauve, orange and yellow.

P. helodoxa.—A very tall grower, with flowers of a clear yellow, with mealy calyces. This species differs from most in being practically evergreen.

P. glycosma and *P. Poissoni.*—Both have purple-mauve flowers and glossy foliage, the former distinctly scented.

P. pulverulenta.—A strong grower with large flowers of wine purple and mealy stems, reaching up to about 4ft. high. From this variety there has been raised, at Bartley by Mr. G. H. Dalrymple, a strain of delightful pink varieties. This strain has now been fixed and seed reproduces all pink. The finest variety is Lady Thursby, a beautiful shade of rose pink.

P. Lissadell hybrids.—These are a strain of chiefly vivid orange-scarlet shades, the result of crossing P. pulverulenta and P. Cockburniana. The latter is a wonderful colour, but a small plant and a biennial. The hybrids have size and habit similar to P. pulverulenta, though not quite so large. Several varieties are named, Red Hugh and Ailin Aroon, both raised at Lissadel. They seed freely and reproduce fairly true.

Of other easily grown species which will grow under similar conditions, there are *P. rosea*, an early flowering species, with bright rose flowers, of dwarf habit when first opening, the flower spikes have grown many inches by the time the seed pods are ripe and as these ripen early, watch must be kept or the seed will be lost. This species seems to prefer much moister conditions, though I have it growing very well in a cool, but drier position.

P. luteola, with soft yellow flowers, seems to prefer more moisture than most. *P. vittata* is somewhat similar to P. secundiflora, but is smaller in the flower and I think has rather more of them; they could be best described as purple forms of the well known P. sikkimensis, the Sikkim cowslip, a delightful scented variety with hanging heads of pale yellow flowers. This seems more or less biennial and I have noticed the vast difference in plants of this species and P. vittata, when growing in ground saturated by a spring which always keeps the ground sweet.

P. Florindæ, which received a F.C.C. at Chelsea last year, is one of the latest introductions. It is a giant sikkimensis and from the collector's description it should be a fine garden plant.

P. chionantha, which has white flowers and belongs to the Nivalis section, is not long lived with me. This may be a matter of cultivation; it is a plant worth persevering with.

The last I shall mention is the extraordinary looking *P. Littoniana*, which has a cone-shaped flower spike, a strange contrast in its purple flowers and red calyces. It is difficult to keep perennial, but it is well worth tackling, for it is so unlike anything else. That it is perennial is proved by a letter I had from a gentleman in Ireland, who has plants several years old, throwing up ten or more spikes

Digitized by Google

each. No doubt the climate of Ireland, and, I believe, also Scotland, suits it, like many other primulas. Personally, I find it does best when planted where it gets good drainage in its resting period and sufficient moisture in its growing season. It dies down to a small hard bud and as it starts into growth very late, it is apt to be overlooked. In frosty weather it is apt to be "lifted" out of the ground, as its roots being spread near the surface have not much hold. I have found it very easy to raise from seed. P. M. A.

EVERGREEN SHRUBS FOR SMALL GARDENS

ONE very valuable characteristic of evergreen shrubs in connection with small gardens is that the majority can be kept small, or within reasonable limits, by pruning. Neither need this destroy their distinctive character and beauty of flowering. The best time to prune most evergreen shrubs is during April and May. At this season new growth is more active than at any other season of the year, and even if severe pruning is considered necessary, the bushes are soon furnished with new growths. One of the important shrubs which can be pruned in early April is the laurustinus, because flowering has finished, while the pruning of Berberis Darwinii and B. stenophylla must be delayed until the flowers fall.

Instead of planting laurels, privets and even yews so extensively in small gardens, choice should be made, as far as possible, of shrubs, which in addition to being evergreen, have attractive and showy blossoms. They are little, if any, more trouble to grow and care for, while bearing no comparison in interest and beauty.

As an alternative to the usual privet hedge of the small front garden, I suggest planting a selection of six, eight or ten from the following list of shrubs: Berberis stenophylla and B. Darwinii, Cistus cyprius for a hot sunny position, Ceanothus dentatus, Mahonia Aquifolium, Olearia Haastii, Escallonia langleyensis, Osmanthus Delavayi, Pyracantha Lalandei, Veronica Traversii and Viburnum Tinus (laurustinus).

It is neither possible nor desirable to keep the growths of these beautiful shrubs closely cut with shears once a month in summer, as is done with privet, but all can be kept quite formal and moderate in size by pruning, except, perhaps, Cistus cyprius, which is not improved with the knife. Some owners may prefer to plant only one variety of shrub, or a selection of three, one along the front and one on either side.

My choice of half a dozen small specimen shrubs for a tiny front garden would be Erica carnea, which grows in limestone soils and produces its rosy-red flowers from January to April on plants less than 1ft. high; Rhododendron racemosum, which also does not seem to be impatient of lime in the ground, white pink-tinted flowers in April; Yucca recurvifolia, a plant with dracæna-like foliage which occasionally develops a tall stem of creamy-white blossoms; Mahonia Aquifolium, the Oregon grape, should find a place in the majority of small gardens. In sunny positions it has large attractive glossy green leaves, which in winter assume a bronze or purple shade when sprays are valuable to cut for vase decoration with flowers. In early spring erect clusters of rich yellow blossoms top the foliage, followed by violet-black fruits, beloved of the blackbirds and thrushes. This mahonia is also one of the best shrubs to plant in shaded positions and beneath trees. Normally 4ft. to 6ft. high the bushes can be kept to half these heights by periodical pruning. Berberis Darwinii nana is a dwarf form of the Chilian barberry, with golden-yellow blossoms. For a hot, sunny position Cistus corbariensis forms a neat, compact bush, covered in June and July with white blossoms 1½ins. across.

SHRUBBY VERONICAS ARE DECORATIVE BOTH IN FLOWER AND FOLIAGE AND WORTHY OF A PLACE IN FRONT OF THE HOUSE.

Several evergreen shrubs are very good climbers to clothe

House Walls.

As there is some difficulty in successfully transplanting these shrubs, nurserymen cultivate them in pots so that they are available for planting at the present time. Garden lovers who have taken occupation of a new house at the end of the March quarter can thus proceed with the planting without delay. The most popular evergreen on London suburban houses is Pyracantha Lalandei. It is planted with success in all four aspects, but on north walls the position must be open with all possible light. In spring it has clusters of white may-like blossoms followed by orange scarlet fruits. For a south or west wall the blue-flowered ceanothuses are very showy and valuable. C. rigidus is the best for a small area, as the branches are stiff and compact. C. dentatus is more robust in growth, while to clothe a wall of ample proportion, plant C. Veitchianus. The common myrtle, Myrtus communis, or the small-leaved myrtle, M. tarentina, are also suitable for a south or west wall. The rather new Chinese shrub with fragrant white blossoms, Osmanthus Delavayi, is a very good subject for a warm sheltered wall. On an east wall plant the evergreen honeysuckle, Lonicera Halliana.

The following shrubs are worthy of consideration as specimen evergreen

Lawn Shrubs

for a small garden; Veronica Traversii, white; Olearia Haastii, the New Zealand daisy bush, white; Rhododendron hippophæoides, a small leaved Chinese shrub with lilac purple blossoms; Osmanthus Delavayi, if the garden is warm; Raphiolepis Delacouri is a little known hybrid shrub with panicles of pink blossoms in summer. It belongs to the rose family. Cotoneaster salicifolia is a graceful, free-flowering species from China with white flowers and red fruits.

Enough names of evergreen shrubs have already been enumerated in these notes to furnish a shrubbery border in a small garden and gardens of moderate size. There are, however, several of distinctive merit and deserving of attention when the particular conditions quoted are available.

The value of camellias as hardy shrubs is appreciated in very few gardens. They are quite hardy shrubs, but because the blossoms are produced in late winter and early spring, plant in sheltered positions. When a plant becomes too large for its pot in the greenhouse give it a warm sheltered corner in the garden border.

Dabœcia polifolia, the Irish or St. Dabeoc's heath, is a dwarf evergreen shrub 1ft. to 2ft. high. There are varieties with rosy-purple, red-purple, white and purple (bicolor) and pure white blossoms, freely produced from June to late autumn. It likes a peaty or lime-free, loamy soil. A. O.

THE BUSY MAN'S PAGE

When the Peas Come Up.

BOTH in the case of sweet peas and green peas the little plants often find it rather difficult to secure an immediate hold. This is because the lower parts of the sticks are too thick for the tendrils to embrace. When this happens the young plants spend some days more or less sprawling on the ground until they have grown to a sufficient height to grasp hold of the finer twigs. In all ways it is better to get the young pea plants clear of the ground at the earliest possible moment so that, with the appearance of the first tendrils, they may develop their proper climbing habits. It is an excellent plan to arrange a number of small twigs round the bases of the sticks, pushing one end into the ground and letting the other lead upwards. The peas will be quick to take advantage of the support offered and there will be no check on the development of the plants.

Pruning Climbing Roses.

IN a general sense when pruning climbing roses steps should be taken to remove all the old wood, that which is young alone being retained. In most cases this is a good line to follow but, now and again, it is needful to discriminate a little. In many cases young wood is abundant, and here one can usefully do without the old wood. It sometimes happens that only a few new growths have been produced, and yet a large space has to be covered, and here it would be a mistake to thin out too severely. This applies especially to the Wichuraiana roses, of which Dorothy Perkins is a well known example. Here, if the growths which flowered a year ago are examined, they will be seen to differ from the young growths in that they have short shoots along them and these bore the blossoms during the previous season. If it should be necessary to retain a few of the older shoots, cut these back to a couple of buds from the main shoot. This will make them break into growth fairly strongly, and the young growth will, in due course, flower, although the blossoms are rarely so fine as those produced on perfectly new stems. Such roses as Hiawatha, Minnehaha, Lady Gay, in addition to Dorothy Perkins, may be treated in this manner. It should be realised that this plan is not to be recommended where strong, well ripened stems of the previous season's growth are available in sufficient quantity. It is important to distinguish between the Wichuraiana and the rambler roses proper (like the Crimson Rambler), for these latter varieties give very indifferent results from the old stems.

Planting Evergreen Hedges.

AS a rule evergreen hedges are superior to hedges of deciduous shrubs, for they form dense screens, protective shelters and, at all seasons, a pretty and decorative garden ornament. This is one of the best periods

PLANTS IN THE POSITION FOR PLANTING.
They are laid out at the necessary distance apart.

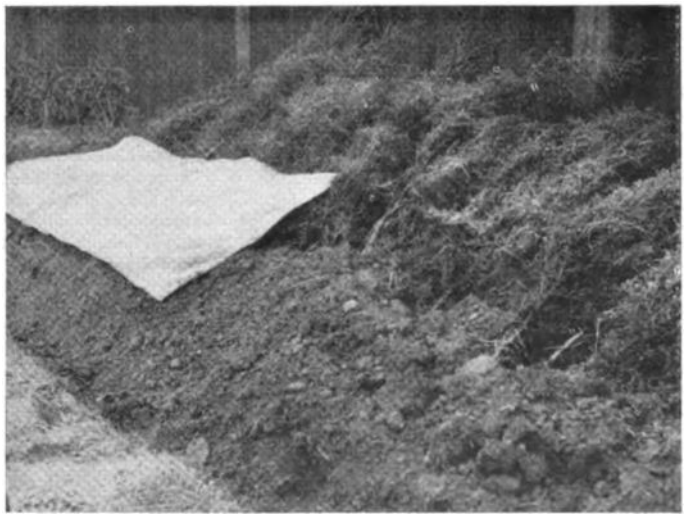
of the year in which to plant; shrubs may be obtained or shifted successfully, the ground is easily prepared for them and the work can be properly carried out. As the hedge must stand for a long time, the grower should devote time and attention to the preliminary soil preparation. The soil should be dug to a good depth, at least a foot on either side and if it is not in good heart a liberal addition of really old manure or leaf-mould or, preferably, a mixture of both, should be added. Evergreens may be purchased "full grown"; by this is meant that the hedge may be made to any desirable height, by purchasing shrubs of the requisite size. Such large shrubs are planted touching one another, so that the hedge may be a close one, but if for economy or for some other reason, small shrubs are obtained, they may be planted from 1ft. to 18ins. apart; the closer they are to begin with, the quicker will the hedge fill up. Small privet may be planted in a double row thus—

. . . . . .

the plants being 9ins. apart and the rows 4ins. to 6ins. from each other, in order to get a full hedge quickly. Full-sized evergreens should not be cut after planting; let them remain as they are until they show signs of having "taken" to their new position first, then cut, if desired, or leave them until next spring. Drought is always a danger after planting evergreens; water the soil copiously for a time, if necessary, spray the foliage occasionally and mulch alongside so as to keep the soil moist. One of the best evergreens for a hedge is Cupressus macrocarpa. In the accompanying illustrations is shown the planting of a hedge of this fine conifer in a new garden. It is an especially useful plant, a rapid grower, and does well in the majority of soils. The plants should be spaced about 18ins. to 2ft. apart, and in two or three years time a good bushy hedge will result. Plants can be generally obtained at a cheap rate if purchased by the hundred..

Water Plants After Top-dressing.

OFTEN, after giving a top-dressing of soil, it is considered that no further watering is needed. This is a great mistake, for, just because the top of the added soil is moist, it must not be taken for granted that the whole is in a similar condition. The newly added soil does not dry so quickly as that underneath, simply because the latter is full of roots, while there are none in the former. Generally speaking, plants that have been newly top-dressed need watering almost as often as previously, although to an extent the fresh soil acts as a mulch and keeps away the drying action of the sun and air. All top-dressings should be light and applied frequently, instead of a great deal being put on at one time. If the latter plan is carried out there is a possibility of the new soil becoming sour from constant watering before roots can enter it.



HEELING IN THE PLANTS ON ARRIVAL FROM A NURSERY.
Note the covering of soil and a canvas mat to prevent the drying out of the roots.

THE BEGINNING OF THE HEDGE.
The plants are placed at a distance of about 2ft. apart, and after planting the straggly branches should receive a slight clipping.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

A Flower for Poor Soil.

IT is easy for the expert to advise "a liberal dressing of well decayed manure," but it is not so easy for the owner of a small town garden to obtain it, and even if he can get it he has probably to pay dearly for it. This is one reason why many town gardens, which have been sown and planted for a number of years, are extremely impoverished, and quite unable to feed those plants which need a rich soil. The antirrhinum (or snapdragon) is a plant which will do well in poor soil. It is not particular regarding atmosphere and gives a wealth of coloured blossoms even in the most congested parts, and so may truly be said to be a town flower.

Of course, larger and more abundant flowers are produced if a dressing of suitable fertiliser is applied to the soil when digging is done. Any of the proprietary fertilisers recommended for flower production, applied at the rate of 2 oz. or 3 oz. to the square yard, would be beneficial; and any decayed leaves or vegetable matter or manure that may be available should be worked in as digging is done.

Choose the sunniest spot in the garden for snapdragons. A magnificent display can be obtained in a bed by planting exclusively snapdragons in different varieties. I doubt if anyone could say how many varieties of this fascinating flower are now offered by seedsmen. But for simplicity, they are grouped as dwarf, intermediate and tall, varying in height from 6ins. to 3ft. For decorative purposes and for exhibition the intermediate and tall varieties are best; but the tall varieties tend to flop over and therefore are not so satisfactory for ordinary bedding as are the intermediates and dwarfs. The leading seedsmen have their own named varieties, but there are number which are offered by all. The following can be relied on to make a vivid splash of colour in the garden: Bonfire (orange scarlet), Scarlet King, Golden Queen, Daphne (deep rose and white), Black Prince (dark crimson, with dark foliage), Victory (terra cotta), and Amber Queen (yellow with chamois pink).

Seed Sowing and Transplanting.

Seeds are best sown in boxes, protected by a sheet of glass, or in a cold frame, and then transplanted into their flowering quarters. Where space is limited or when seed sowing is delayed too long, it is advisable to buy small plants in boxes for bedding out. The plants should be set out in their permanent quarters from 12—18 ins. apart, according to their height.

Care of a Cold Frame.

Ventilating the Cold Frame.

HAVE you seedlings or cuttings in your cold frame? And, if so, are you being specially careful about the ventilation of the frame? There is no season of the year which brings a greater crop of fatalities in the frames than just now, when the days become warm while the nights may at any time bring a recurrence of frosts. A frame left quite closed on a hot sunny day may cause the plants to become "drawn": that is, to grow long stems between each of the joints. Such plants never grow into shapely and bushy specimens. A closed frame may also cause worse damage. I have seen several boxes of seedlings scorched and rendered useless by one day spent in a closed frame while the sun was hot.

On fine days the lights of frames used for violas, antirrhinums and other fairly hardy plants may be removed entirely. On chilly days the light should be raised on the side away from the winds. About half an hour before sundown the lights may be replaced; but in the case of hardy plants which are soon to be transplanted to the open, there is no need to close the frame entirely at any time. Leave it always so that the plants get plenty of air, and they will grow more sturdy, and give better results.

It is time to transplant rooted cuttings of violas and pansies. Pinch out the tips of calceolarias and gradually harden them off in readiness for summer bedding.

Pool and Bog Gardens.

THE gardener is fortunate who has a stream running past the end of his garden, for this, properly planted, can be made into a perfect picture. Even where there is no natural water it is not impossible, to arrange a bog garden by making use of the rain water drained from greenhouses, sheds, etc. A deep pond, dug out to a depth of about 3ft. or 4ft., with cemented and slated sides and bottom, can be made by any amateur. This is an ideal place in which to plant some of the charming water lilies, such as Nymphæa pygmæa Helvola or N. odorata alba (very fragrant). If the water from such a pond is allowed to overflow into the surrounding soil, a bog garden can be made by suitable planting. Add peat-moss litter and decayed leaves to the soil to retain moisture.

A few plants which would do well in such a position are Iris Kæmpferi, I. lævigata, Parnassia palustris, Primulas japonica, Beesiana and Bulleyana, Butomus umbellatus (Flowering Rush), Sagittaria japonica, hart's tongue ferns, Trollius europæus, Astilbe Thunbergii, Viola palustris, Meconopsis Wallichii, Myosotis palustris, and Caltha palustris fl. pl.

A SMALL LILY POND MAKES A MOST CHARMING ADDITION TO A TOWN GARDEN.

Salads for the Town Garden.

COOL, crisp, refreshing salads are best made from newly gathered lettuces, radishes, etc., such as it is only possible to obtain when these are grown in one's own garden. Town and suburban gardeners need not be debarred from such joys, as even in the small garden it is quite possible to cultivate many salad crops successfully. The secret of success in salad culture is in rapid growth, and this can only be secured when moisture, warmth and a fairly rich soil are available. The allotment gardener often plants out his salads between tall-growing crops, thus affording them a certain amount of shade and preventing scorching. The owner of a tiny garden need not usually worry about excessive sunshine, as it is probable that even the sunniest parts get a limited quantity of shade either from his own or neighbours' houses.

Mustard and Cress.—These are favourites in the salad bowl, and to keep a constant supply available they should be sown in succession at fortnightly intervals. It is best to sow in boxes, as seed sown in the open ground is an attraction to sparrows. Use finely sifted soil for the top layer, and spread the seed thickly over the surface. Place a sheet of paper over the seed until germination has taken place, but do not put soil over the seed. The crop will be ready a few days after the paper is removed. Do not forget to keep the boxes moist, but not too wet, and never use the same soil twice.

Lettuce.—This crop entails comparatively little trouble, and can be grown in almost any position. Seeds may be sown in boxes in cold frames or in the open ground, and then transplanted as soon as they are large enough to handle. Thinning and transplanting must be done early, otherwise the plants will become straggly and have a tendency to bolt instead of developing hearts. Eight inches apart is not too much room to leave the plants. From the time of sowing it takes ten to twelve weeks for lettuces to develop into good-sized plants.

Radishes.—These are another crop which should be grown in every garden. A few seeds scattered thinly, preferably in a shady part of the garden, and covered with a thin layer of sifted soil will mature in about five or six weeks. The turnip-rooted radishes are best for town culture.

WORK IN THE FLOWER GARDEN

A Blue Flower for the Border.

I BELIEVE we are indebted to Mr. Forrest for the introduction of Cynoglossum amabile (Hound's-tongue), who discovered it in Tengyueh, China. It is a fine acquisition, and should be largely grown in beds and borders. The leaves and flower stalks are a pleasing grey-green, the brilliant blue forget-me-not-like flowers being produced in spreading panicles about 18ins. or 2ft. in height. Truly it is a fine plant, and now we have a pretty form known as Blue Gem, and this should be grown by all who desire an effective subject for the blue garden or border, while, of course, it is equally appreciated among other flowers.

It is biennial in character, and seeds should be sown about July to furnish a supply of plants for next year, when an early display of bloom will be assured. There is, however, a possibility of securing flowering plants this year if seeds are sown at once, and grown on without any check. Plants so raised will afford a striking feature in the garden about September or October, and a bold group is most conspicuous when in flower. It is readily raised from seeds, and presents no difficulty regarding cultivation. A few plants will carry on for another season, and often a number of self-sown seedlings will appear.—T. W. B.

A Mignonette Tree.

A Novel Way of Growing this Fragrant Annual.

IN these bustling days, few people, I am afraid, have the necessary patience to grow a mignonette tree, a labour of love which appealed strongly to our grandmothers, many of whom were clever window gardeners, but such an experiment is interesting and well worth trying. There are two ways of making a start; a few seeds may be sown in a 6in. pot during April in a frame, or failing this, a sunny window, and the seedlings reduced first to three and then to a single one, or a sturdy seedling may be potted up from the open ground in May or early June, but whichever method is followed, the after procedure is the same. When the plant is about 4ins. high, the lower leaves should be removed; this must be repeated several times, until the effect of a tiny standard tree is obtained, and about July or August the top should be pinched out to encourage branching. Every flower bud must be nipped out promptly throughout the summer. If the pot is well filled with roots the little "tree" should be repotted at the end of September or early in October, and placed in a greenhouse, or in the window of a room from which frost is excluded. By the following spring a film of bark will probably appear on the little "trunk," and if care is taken to remove all buds during the ensuing summer, the tree will bloom profusely through the next winter under glass or in a window, or it may be grown on for another year before it is allowed to flower. I have seen in a gardening book published in the 'sixties of last century, that a mignonette tree will "last and bloom for years," but, as a rule, after a crop of flowers has been produced, it dies. I confess I have only once attempted to grow a mignonette tree myself; then all went well until it had attained some size and I was just thinking of permitting it to bloom, when, alas! a swarm of tiny green caterpillars took possession of it and before the invasion was noticed had reduced the pretty little tree to a bare pole—and so it died. But some day I hope to try again.—R. E. H.

Sow Zinnias Now.

THE zinnia is at once one of our showiest and most easily grown annuals. Asters are quite impossible on some soils. Stocks are subject to—among other ailments—the club-root or "finger and toe" disease which attacks the roots of the cabbage family and other cruciferous plants. The zinnia, though it sometimes suffers a little in a wet cold autumn from a fungus "die-back" disease, is, under decent cultural conditions, relatively immune.

CYNOGLOSSUM AMABILE MAKES A FINE EDGING PLANT.

The perfection of form shown by the flower-heads of a good double strain is such that, in conjunction with the characteristic "lacquered finish" to the florets, it imparts an effect of quaintness bordering on artificiality. But the plants, as growing, are "real" enough, for there is nothing artificial about the foliage. The "finish" to the florets makes any colouring in the zinnia reminiscent of art work carried out in sealing-wax; and tones and shades which—in the aster, for instance—would be dull and muddy, look very clean and charming in the flower under discussion. The writer is not, as a rule, enamoured of "art" colourings in flowers, but a packet of Suttons' Art Shades Zinnias tried during the past season provided a feast of charming colours—cream buff and shades of apricot and rose, with crimson lake tones, predominated. Other pleasing and unusual strains obtainable are the cactus-flowered and picotee-edged; while the single forms, though different in their attraction, should by no means be neglected. For edgings and foregrounds the miniature or pompon varieties should be much more frequently met with than is actually the case. It should also be borne in mind that large-flowered double zinnias may be had of various habits to suit varying conditions; the dwarf forms seldom exceeding a foot in height, while the giant strains will attain 2½ft. or even more. All strains, except the very tallest, are eminently suitable for filling good-sized garden vases.

As already suggested, the culture of zinnias is of the simplest. The large seeds should be sown thinly in a fairly rich compost, and pricking off should not be delayed until the plants show a tendency to become drawn. Gentle heat for germination and early growth is useful, but by no means essential. A cold house or even a cold frame will raise splendid plants. The great secret of success with the zinnia is, however, *not to sow too soon*. The third week in April is quite soon enough where the plants are intended for bedding out.—G. W.

Lungworts for the Rockery.

AMONG the old-fashioned flowers which have found a place in English gardens for many years are the lungworts (pulmonarias), and, although they are not showy, they possess a certain charm that appeals to a large number of gardeners. The value and interest of a garden is the variety of plants grown, and here we have a small group of early-flowering subjects that are in striking contrast to the numerous bulbous plants and wallflowers that are in bloom at the same time, *viz.*, March and April, according to the season. Only a few species will be found in catalogues, and they are all useful, if not indispensable, to the rock garden and front positions in the herbaceous border. One of the best is Pulmonaria azurea, sometimes quoted as angustifolia. It grows about 9ins. high, and its rich gentian blue flowers can occasionally be seen in February; but the finest display for this charming plant is between March and May.

Another good blue form is Munstead variety with clear blue flowers and green foliage. One often met with is P. saccharata, which has handsome silver and green leaves and pretty pink flowers which, with age, turn to a violet shade. There are two or three forms of P. saccharata, such as picta with blue flowers, and Mrs. Moon with bright salmon pink blossoms marked with blue, the green foliage in this variety being beautifully mottled with white.

There are a few other pulmonarias, such as rubra with coral red flowers, but the above are about the cream of the group, and they will furnish a delightful bit of colour in the early spring, while the foliage as it develops will be quite a feature of the border during the early summer. They are of easy culture, thriving in ordinary soil, while they can be grown in the shade as well as in the sunshine, and I have seen them producing a good display of bloom beneath deciduous trees. They can be increased by division, and by seeds.—CHEPSTOW.

Raising Dahlias from Seed.

IT is quite evident that dahlias are again becoming very popular. This, no doubt, is partly due to the many beautiful types and strains that have been added to the list in quite recent times, noteworthy on account of their wide range of colour and various methods of decoration to which they lend themselves.

The method of raising these flowers from seed is now more generally adopted than in the past. Although one cannot rely upon obtaining true colours from seed, it is, nevertheless, most interesting to note the various forms and pleasing shades obtained by this means. Seed sown at once in gentle heat will yield good strong plants ready for the border at the beginning of June and will produce a grand display of bloom the first season. When the seedlings are large enough to handle, pot off singly into large 60s, and once they are established they will soon make up into sturdy plants. Gradually harden them off in readiness for planting in their permanent quarters. Given the necessary attention in the matter of staking and tying, they well repay for any time spent on them. Mulching and watering during hot weather are most beneficial and are essential if the best is to be derived from them.

To obtain the best varieties, it is wise to procure the seed from a reliable firm, even at a little higher cost.—W. F.

SEEDLING DAHLIAS IN ALL COLOURS ARE EXCELLENT FOR BEDS AND BORDERS.

Sweet Pea Seedlings.

Transplanting to their Flowering Positions.

THE sweet pea seedlings which have safely passed the winter in frames and greenhouses, are now almost ready for transplanting. This should be done gradually, in order that the seedlings shall become hardy and accustomed to the outside air.

Keep the frame lights open a little wider each night until the seedlings within are fully exposed to the weather. Meanwhile fork over the border where the sweet peas are to go; of course, all manuring should have taken place in autumn or early spring, but if for any reason this operation should have been neglected, now is the time to do it. Dig a long trench, 2ft. deep, and spread a thin layer of well rotted cow or stable manure along the bottom; fill in again and mix a little bone meal with the top spit. Bone meal is an excellent and gentle fertiliser which will nourish the plants for months.

Choose a fine day to transplant the seedlings, which by this time will have reached a height of 6ins. or 7ins., and which already should have been pinched back to make bushy plants. Raise the seedlings carefully out of the frame, and before transplanting them along the border, dip the roots in a jar of water. Press the soil firmly about the roots and support the stems with a few twigs pending the arrival of the pea sticks.

In this way the process of transplanting will cause no set back to the seedlings, which under the influence of rain and sunshine will soon develop into sturdy plants bearing rich crops of flowers throughout the summer. —G. J. M.

Scabiosa caucasica.

FEW gardens, however small, can afford to be without one or more representatives of Scabiosa caucasica, and now that flowers are being grown for the London markets they are sure to become popular during the coming summer. They are splendid border plants, while for cutting purposes they have no equal. Few other border subjects continue in bloom for so long a period. Slugs are the greatest enemies of these beautiful scabious, but liberal applications of air-slaked lime and sharp grit during the winter months will keep these marauders away.

The question of planting is most important, and the best time is from March to July, and *not* September to March, which is the period to plant most things in the borders. In fact, it is disastrous to lift and divide S. caucasica during the late autumn and winter months, so March or early April would be the ideal time for most gardens.

They are perennial, hardy, and need no staking. It is a good plan to grow them in a separate bed or border, but where it is decided to place them among the herbaceous plants, choose an open site where they will not be overwhelmed with dense foliage. Every second year division of the plants must be resorted to, if the best results are to be obtained, and this should be done in March or early April. A distance of a foot or 18ins. is allowed between the plants, and, when the stock increases, try a row across the kitchen garden, where, more or less forgotten, they will furnish a quantity of first-rate blooms for vases and general decoration. In addition to the type of S. caucasica, which produces lovely heads soft of lilac-blue flowers on stiff stems, there are numerous first-rate varieties, such as Harold, deep iris blue; Mauve Queen, lavender mauve; Isaac House, intense violet blue; and others.

These are a little higher in price than S. caucasica, which is on a par with other common hardy plants. Seeds from named varieties are offered, and these can be raised now in a cold frame, and directly the seedlings are large enough transfer them to their flowering quarters. The raising of seedlings is an interesting pursuit, and there is always the possibility of flowering a really fine variety; in any case, the majority will be of value for the border.—T. BRISCOE.

MODERN PERENNIAL SCABIOUS WITH LARGE WELL FORMED FLOWERS.

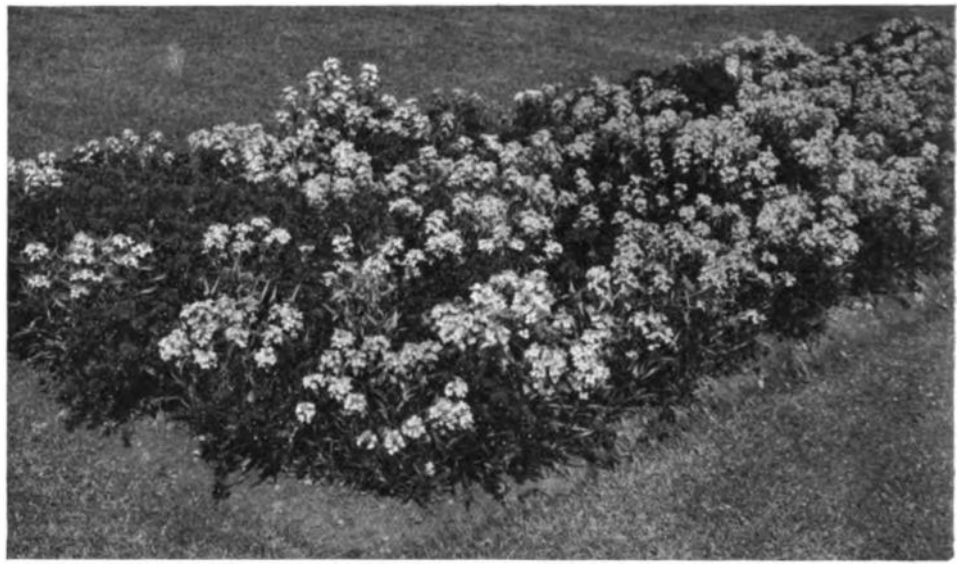
SOME GOOD BIENNIALS for BEDS or BORDERS



A BED OF THE BRILLIANT ORANGE SIBERIAN WALLFLOWER WITH A GROUNDWORK OF BLUE VIOLAS.

OF late years it has been increasingly the custom to treat many biennials as half-hardy annuals, sowing them in slight heat in February or March and planting out in May or June for flowering the same season. The plan is a good one, as it saves the seedlings from the perils of severe frosts, torrential rains and the attacks of slugs and snails which beset them if sown in autumn out of doors. But it is not everyone who has heat at command, nor is it every biennial that responds satisfactorily to the treatment.

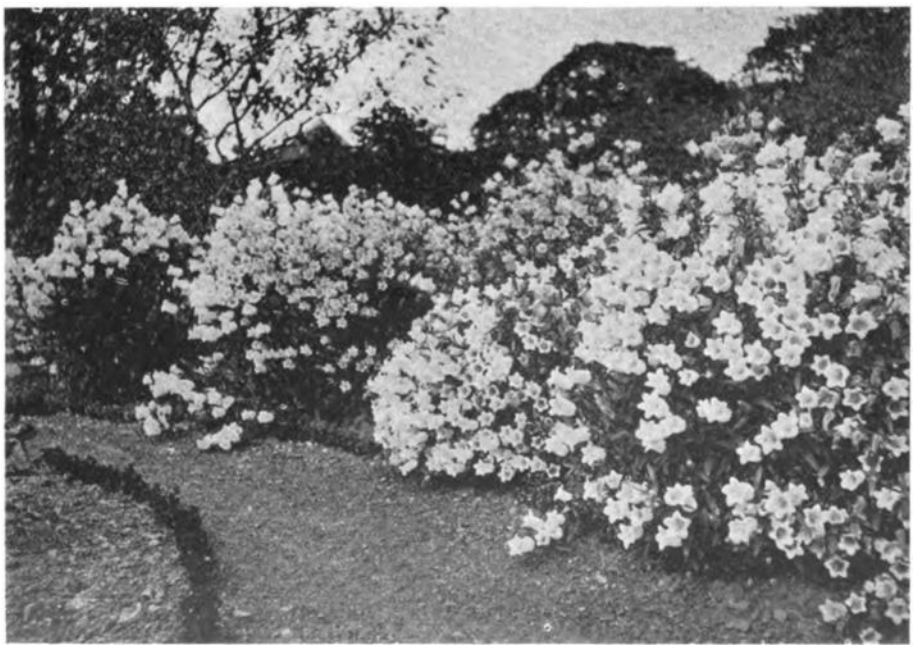
One of the best and hardiest true biennials is Campanula Medium, better known as the Canterbury bell. The seed of this, which is extremely fine and should be only just covered with sifted soil, should be sown out of doors early in summer (for the campanula is not a quick grower); the seedlings, pricked out for the autumn and removed from the nursery bed to their flowering quarters in May or June for blooming the same season. The single Canterbury bells are undoubtedly the most graceful of habit, but the doubles and semi-doubles or cup-and-saucer (C. calycanthemum) varieties are showier and therefore more popular. A bed of either single or double Canterbury bells—they are best used separately—in mixed colours, mauve, purple, pink and white, is a very pretty feature in a garden, whether large or small, and if the seed pods are removed its beauty will continue throughout the summer. Clumps of the campanula, the height of which ranges from 2ft. to 2½ft., are effective in the border, while plants potted up in October for the unheated greenhouse will bloom in early spring.

Handsome plants for the back row of a wide border, especially if combined with delphiniums or with Anchusa italica Dropmore variety or the newer Pride of Dover, are the verbascums or mulleins. Some of these are really biennials, while others are perennials, which are generally grown as the former, which probably explains why a species listed as "biennial" by one seedsman may appear as "perennial" in the catalogue of another. V. phlomoides is a true biennial and is one of the finest of its kind; it has large golden flowers and attains a height of 5ft. or 6ft., as, indeed, do practically all the mulleins. V. olympicum is another good biennial, so is V. Chaixi (perennial in some soils), which has woolly leaves and buff-yellow flowers with a purple eye, and there are some fine biennial hybrids of which Miss Willmott is a beautiful pure white, but these are rather less hardy than those previously named. The verbascums which, as a rule, seed themselves freely, prefer a light soil, as do their relatives, the celsias, of which C. cretica (4ft.) is the most attractive, but C. coromandelica (5ft.), the hardiest. Both are yellow flowered.

An old-fashioned biennial now rarely seen save in cottage gardens is Lunaria biennis, otherwise Honesty, Peter's-pence and Money-in-both-pockets. The purple of the type is a little dingy, perhaps, but L. b. atro-coccinea is a rich crimson-purple and the white variety is excellent for cutting. The shining, silvery white ovals of the seed pods make a pretty winter decoration in the house, especially if arranged with the scarlet lanterns of Physalis Alkekengi or P. Franchetti. Honesty is an essentially good tempered plant; it is quite indifferent as to soil; will bloom tolerably well under trees and can be trusted to renew itself from seed. Sweet William—Dianthus barbatus—is one of the plants catalogued indifferently as perennial and biennial, but it is really the latter. The old auricula-flowered type that has a ring of purple or crimson on a white ground, has a certain pleasing quaintness about it, but Sutton's Pheasant's Eye and Barr's Perfection are both improved varieties of it. The self-coloured varieties, however, are preferable for massing in beds, and of these Sutton's Pink Beauty, Scarlet Beauty, Barr's Copper King, Fairy, Salmon-pink and Sutton's Giant White are specially desirable. Ryder's dwarf Sweet William, only 9ins. high, makes a neat edging and there is a double strain, but this is scarcely as pretty as the single.

Foxgloves are to be reckoned among the most effective plants for the back of a border or as a group in a corner of the garden. The white and spotted varieties are the best to grow and of the latter the Shirley strain, the result of many years careful selection by the Rev. R. Wilks, is by far the most desirable. Sutton's Giant Primrose, with deep cream flowers verging on buff, is a novelty, but scarcely as attractive as the pure white; Digitalis ambigua and D. gloxinioides are curious, but not very beautiful and the original type, D. purpurea, is only suitable for the wild garden. Therefore, any seedlings showing the least trace of the purple-pink of the native plant should be promptly pulled up.

The ever valuable antirrhinum is a perennial which is now almost invariably treated as a half-hardy annual, but it can be grown as a biennial by sowing in June or July and wintering the seedlings in the open ground; they should, however, have some slight protection in an exposed situation. Antirrhinums are now to be had in such an infinite variety of beautiful shades that it is difficult to select any for special commendation, but among the best are certainly Golden Chamois, Orange King, Crimson King, Pink Pearl, Malva Rose (new) and White Queen, all belonging to the tall section, and Nelrose, Fire King, Crimson Queen, Fireflame and Rose Dorée, in the intermediate class. And Messrs. Dobbie have an excellent strain of striped antirrhinums (these have been always popular north of the Tweed), which make a specially charming and uncommon filling for small beds; they are most effective seen by themselves.

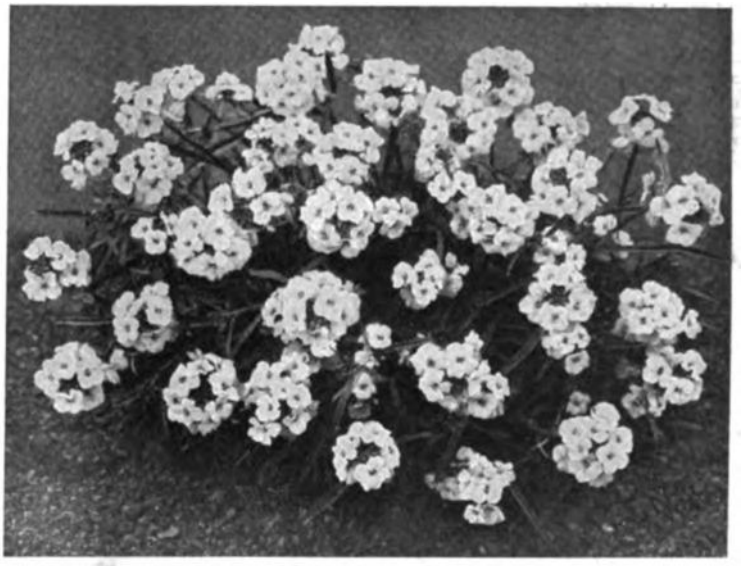


A BED FILLED WITH CANTERBURY BELLS IS ALWAYS ATTRACTIVE.

Digitized by Google

Coreopsis grandiflora, the brilliant golden yellow flowers of which are equally valuable in the border and in a cut state, is ostensibly a perennial, but is so short-lived that it is safest to regard it as a biennial and deal with it accordingly. There is a semi-double and somewhat dwarf variety which is more suitable for a narrow border than the type. The only biennial among the evening primroses is Œnothera biennis and its fine variety Œ. grandiflora (syn. Lamarckiana). The latter has large yellow flowers and reaches a height of 4ft. ; its seed should be sown as soon as ripe.

The practice of growing wallflowers as biennials for spring bedding is increasing and there is an infinite selection of good varieties. Among the most beautiful are Sutton's Fire King, a vivid orange, not far off true scarlet ; Orange Bedder, a softer shade than Fire King ; Faer e Queene, a deep yellowish cream, which goes well with either of the orange wallflowers or with Purple Queen. Ryder's Gold of Ophir is a brilliant yellow and two fine novelties are the ruby-red Queen of Sheba, which is but 10ins. in height, and Rose Queen, the colour of which is really pink with a dash of terra-cotta. And if a very sweet-scented, but not necessarily showy kind is wanted, there is Sutton's Giant Brown, which is a distinct improvement on the old-fashioned type. The wallflower should be sown at the end of May or the beginning of June, as also should the pretty little orange Siberian wallflower, Cheiranthus Allionii, that forms such a delightful carpeting for May-flowering tulips, for, although nominally a perennial, it is a very doubtful one in some soils, and it is wise to renew the stock yearly. The lilac-flowered Erysimum linifolium is a true biennial, as is E. arkansanum, of which Toogood's Dwarf Golden and Sutton's Golden Gem are both good varieties.



THE MAUVE ALPINE WALLFLOWER, ERYSIMUM LINIFOLIUM, FLOWERS IN MAY AND JUNE.

Other biennials worthy of a place in the garden are Eryngium giganteum, the ivory or silver thistle, the nearly white bracts and blossoms of which contrast so well with scarlet orange or deep rose flowers in the border ; Scabious atropurpurea (this can be grown, satisfactorily as an annual) ; the claret-coloured Meconopsis nepaulensis (needs a moist, semi-shady position) ; Iberis gibraltarica, the pretty lilac and white edging plant. R. E. HEAD.

We are indebted to Messrs Sutton and Sons for the illustration of Erysimum linifolium.

WHAT OUR READERS SAY

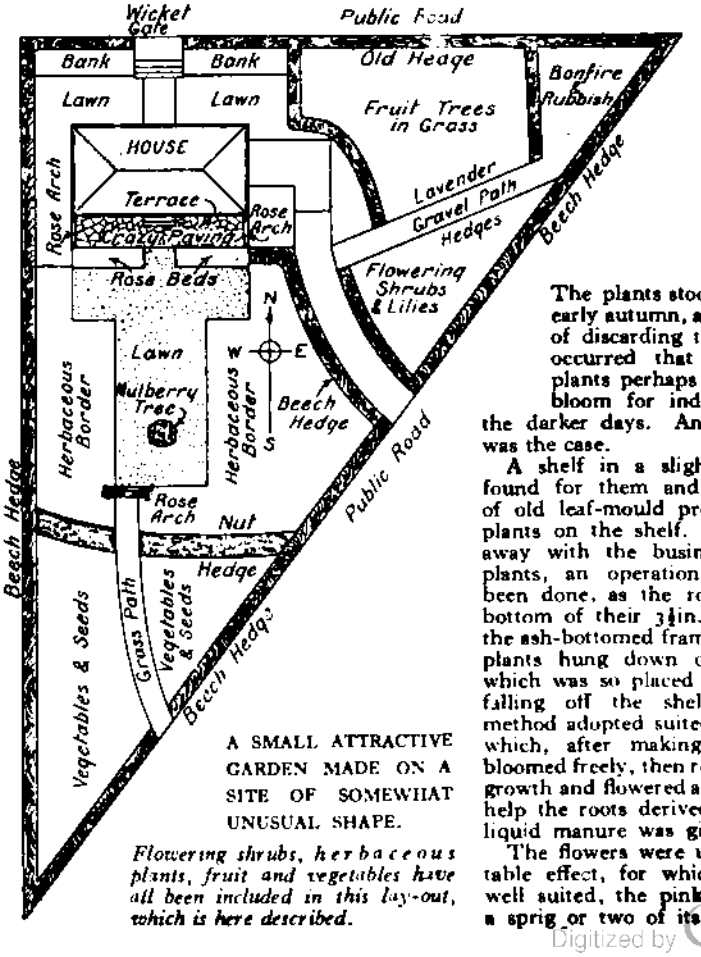
MAKING A GARDEN.

SIR,—Your correspondent, "North Herts," is to be congratulated upon having something different from the eternal rectangular shape from which to make his garden. It may not be so easy, but there is greater opportunity for individuality and a much more interesting result is obtainable.

I imagine my ground is somewhat similar to his, though not so large. Three years ago it was a waste corner on which the local Urban District Council parked a steam roller. The first thing done was to burn the long grass ; then the ground was trenched and the weeds buried a good 2ft. down. Beyond a perennial vetch—the worst weed I know—nothing came up. To get a quick show for the herbaceous borders seeds of delphinium, Anchusa italica Dropmore and Downer's lupins and other herbaceous plants were sown at once and were ready to transplant to the borders as soon as the house was finished.

The rough sketch will show the shape and lay-out of the garden. On the north side there is an old quick hedge. Beech hedges have been planted wherever else a hedge was wanted. Flowering trees being planted at intervals inside the hedge. A Robinia Decaisneana is on either side of the drive gate, and a gingko tree is at the apex of the triangle where the rubbish heap and bonfire are placed. This is screened by a little beech hedge, and while that is growing a parsley-leaved blackberry has been run over a system of wires.

On the north side of the house, which is of a Georgian type, there are a couple of Acacia inermis at the wicket gate, and a couple of pyramid box trees on either side of the front door. On the north wall on either side of the front door, Pyracantha Lalandei and Tropæolum speciosum are growing. On the west, Rose Climbing General McArthur. On the south there is a large oak trellis arch over a French door into the garden. This is covered with honeysuckle—Lonicera Halliana; and against the house at the foot of the wall, Cotoneaster horizontalis. The whole of the east side is covered with Polygonum baldschuanicum. These two last climbers are quite sensational in their tropical growth. I have not got "North Herts'" central depression, but that too could be taken advantage of, unless the house is to be put there ! The thing to do is to choose what will suit the shape of the ground, and then plant only such flowers, shrubs and trees as are likely to be happy in the situation provided. "The Hostel" at Welwyn Garden City, Herts, has a depression in the garden treated in a way which might interest your correspondent. — SOUTH STAFFS.



A SMALL ATTRACTIVE GARDEN MADE ON A SITE OF SOMEWHAT UNUSUAL SHAPE.

Flowering shrubs, herbaceous plants, fruit and vegetables have all been included in this lay-out, which is here described.

IVY-LEAVED PELARGONIUMS.

SIR,—It may be useful to some readers to tell what I did with some spare plants of the above left over from bedding-out and how valuable they proved. The plants stood in a cold frame until early autumn, and I was on the point of discarding them when the thought occurred that were I to house the plants perhaps they would give some bloom for indoor decoration during the darker days. And most assuredly such was the case.

A shelf in a slightly heated house was found for them and covered with a layer of old leaf-mould previous to standing the plants on the shelf. This was done to do away with the business of potting-on the plants, an operation which should have been done, as the roots were through the bottom of their 3½in. pots while standing on the ash-bottomed frame. From the shelf the plants hung down over a strand of wire which was so placed as to prevent the pots falling off the shelf. The position and method adopted suited the plants admirably, which, after making some new growth, bloomed freely, then rested awhile, made more growth and flowered again. In addition to the help the roots derived from the leaf-mould, liquid manure was given twice a week.

The flowers were used chiefly for dinner-table effect, for which this pelargonium is well suited, the pink trusses, among which a sprig or two of its own foliage should be

Digitized by Google

used, contrasting prettily against the white tablecloth. (Incidentally, where growth of this plant does not allow of being cut to mix with the flowers, shoots of any small-leafed ivy from the woodlands will do splendidly.) When the pelargoniums had finished flowering they were thrown out, though, of course, the plants could have been potted on after being cut down, while the tops would have made good cuttings, but they were not wanted.—C. TURNER, *Ampthill*.

AN INTERESTING ASTRANTIA.

SIR,—Masterworts or astrantias, are not very popular plants with the average flower-grower, but there are many who admire them. The majority of the few species in cultivation have silvery white flowers often tinged with rose, and their appearance is unlike the greater number of border flowers. They belong to the Natural Order Umbelliferæ, and show the involucre as the most prominent part of the inflorescence, with a centre of thread-like organs.

They are useful to supply cut flowers, and give a quiet beauty to the arrangement of which they may form a part. Yet to many the presence of some bright colouring would be a gain, and in the species called A. carniolica this is given by the distinct rose tone of the inflorescence. Still finer in this respect is the variety A. carniolica rosea, which has a much brighter tinting to give pleasure. No difficulty is experienced in growing A. carniolica or its variety. Any good soil will answer, and it can be successfully grown in either sun or shade, although I prefer shade. These astrantias grow to a height of about 2ft. more or less. They are finer in a rich deep soil than in a poor one, although, as has been said, they will grow in any soil. Propagation is easily effected by division immediately after the flowering period in summer and autumn or in spring, but they may also be raised from seeds, sown preferably under glass.—S. ARNOTT, *Dumfries*.

VITAGLASS AND PLANTS.

SIR,—Twelve months ago I erected a greenhouse fitted with Vitaglass, and am able to give some results. The most noticeable is intensified colour of flowers and foliage due, no doubt, to the ultra-violet rays. Maximum temperature in a cold house is higher than ordinary glass, but minimum about the same. Lowest temperature for winter 1° above freezing. During March, 1927, highest, 90°; lowest, 40°. I have grown the following plants with results stated:

Genista fragrans.—Deep golden flowers (after planting out in open air a second crop of ordinary yellow flowers).

Zonal Geranium Scarlet King of Denmark.—Healthy dark green leaves, intense scarlet blooms.

Daphne indica rubra.—Rich green leaves, strong growth and perfume; rich colour, flower trusses 2ins. wide, individual flowers ½in. tip to tip.

Tree Peony.—Growth to March 25th 2ft. wide, 1ft. 6ins. high; four flower-buds about the size of golf balls (young plant, first time flowering).

Sweet Peas in pots.—Growth to March 25th, height 3ft., width of stems ⅛in.; strong, bristly leaves; flower-buds starting.

Brussels Sprouts in boxes.—Seed sown a month ago (February 27th), height of plants 4¾ins.

No heating arrangement has been fitted, but I hope to experiment with the house heated next winter. Blinds are fitted, as the primary object of the house is to take sun baths.—S. J. KNILL, *Barnstaple*.

[We should be pleased to hear from other readers who are experimenting with Vitaglass in its relation to plant growth. It seems evident from the experiments being carried out in various parts that there are many points connected with its use on which we require further information.—ED.]

SCHOOL GARDENING.

SIR,—I read with interest the letter published in March 26th issue *re* "School Gardening." My Society has for many years distributed free seeds of annuals to children at the Noel Park Schools; they grow these and bring them for competition to our annual summer show, at which a special school section is provided. Many prizes and certificates are awarded (200 pots of annuals were entered at the 1926 show). In addition this year the children entered pots of daffodils or narcissi at the spring bulb show held last Saturday (April 2nd). In addition to the money prizes, a begonia (gifted by the Anglo-Dutch Bulb Co., of 27, Cannon Street, E.C.) was awarded.—H. C. HUTCHINS (*Hon. Secretary and Treasurer*), *Noel Park Gardening Society*.

SAFEGUARD YOUR FRUIT CROP

MANY amateur growers fail to notice fungus diseases on their trees and bushes until too late in the season, with the result that the damage is done before actual preventive measures are commenced. Growers should therefore keep a sharp look-out for any signs of disease and put curative and remedial measures into operation before any apparent damage is done and more especially if diseases have been troublesome in the past. In the following notes an attempt is made to describe the fungus diseases commonly found on fruit trees and bushes and to state briefly the best means of combating them.

Apple and Pear Scab.

The diseases which cause scab and cracks on the apple and pear fruits are undoubtedly the most widespread, but fortunately for the grower they are the easiest to control. The fungi which attacks the apple is of a different species from that found on the pear, but the damage done and control measures are identical.

The fungus appears on the leaves in early summer as round dark, sooty-like patches and from there the spores are carried to the fruit and shoots by wind and other agencies. When the spores alight they quickly germinate and form mycelium underneath the skin, causing the fruit to crack and become misshapen, soon after thousands of spores are liberated and pass on to the shoots, causing blistered patches all over the bark as if eaten and gnawed by insects. To control this pest and prevent scab on the fruits, careful cutting off and burning all blistered wood and spraying the trees with a weak solution of lime-sulphur before the blossom opens and again when the fruit sets, will prevent a recurrence of the disease this and next year.

Apple Blossom Wilt.

The first indication of apple blossom wilt is the wilted and dead flower trusses, later on the stems have a weathered appearance. The spur growth droops and the dead flowers and leaves do not fall off, but cling to the spurs. If the disease has gained much headway, cut out all weathered flower trusses and prevent further infection. When the disease is slight the trees should be sprayed before the flowers open and again directly the fruit is set, with a weak solution of Burgundy mixture.

The following February trees must be sprayed with caustic soda, made up in the proportions of 1lb. caustic soda, ¼lb. soft soap in 5 gallons water.

Apple Mildew.

This is caused by a superficial fungus which appears as a white, powdery mould on the tips of the young shoots and on the leaf

SOME FUNGUS DISEASES AND THEIR REMEDIES.

Disease.	*Part of Plant Attacked.*	*Remedial Measures.*	*Quantity.*	*Time to Apply.*
1. Apple and Pear Scab.	Leaves, shoots and fruit.	Spray with lime-sulphur.	1 pint in 10 gallons water.	Before flower opens and directly fruit sets.
2. Apple Blossom Wilt.	Shoots, flower and fruit.	Spray with Burgundy mixture.	1lb. in 10 gallons water.	Before flower opens and directly fruit sets.
3. Apple Mildew	Leaves and shoots.	Spray with lime-sulphur.	1 pint in 10 gallons water.	During summer months.
4. Brown Rot of Cherries and Plums.	Wood, flower and fruit.	Spray with Burgundy mixture.	1lb. in 10 gallons water.	Before flower opens and directly fruit sets.
5. Peach Leaf Curl	Leaves and young shoots.	Spray with Burgundy mixture.	1lb. in 10 gallons water.	During summer months.
6. Coral Spot Disease.	Shoots and spurs.	Cut out and burn all dead wood.		During summer months.
7. American Gooseberry Mildew.	Leaves, shoots and fruit.	Spray with washing soda.	1lb. washing soda, 2oz. soft soap in 4 gallons water.	May and June.
8. Strawberry Mildew.	Leaves and fruit.	Dust with flowers of sulphur.		Before fruit sets.
		Spray with lime-sulphur.	1 pint in 5 gallons water.	After fruit is pulled.

Digitized by Google

spurs during summer ; later on in the season the shoots are stunted in their growth and the leaves show a curled-up and weathered appearance, many being entirely killed. The disease passes the winter on the wood, which is generally white and spindly. Those resting spores are readily spread to neighbouring trees by air currents. Varieties which are more or less susceptible to this disease are Golden Spire, Early Victoria, Lord Grosvenor, Cellini, Bismarck and Allington Pippin. Occasional spraying with a weak solution of lime-sulphur during summer will be found effective in keeping it in check, also careful cutting out and burning all affected shoots as they appear on the trees.

Brown Rot of Cherries and Plums.

This fungus disease attacks the flower, fruit and wood. The mycelium enters the fruits, causing them to become hard and "mummified" Those "mummified" fruits are covered with thousands of spores, which are liberated in spring and spread again to the flower and young fruit after they are set. When brown rot becomes severe, numerous dead spurs can be seen on the cherry and plum trees covered with grey pustules. The measures of control for this disease are first, removal of all "mummified" fruits and thus prevent infection the following year. Second, cut out all dead spurs when grey pustules are seen. Third, spray with Burgundy mixture before the flower opens and again directly the fruit sets, and as a further precaution cherry and plum trees should be sprayed in February with a caustic soda wash.

THE FRUIT AND LEAVES OF A PLUM TREE BADLY ATTACKED WITH BROWN ROT.

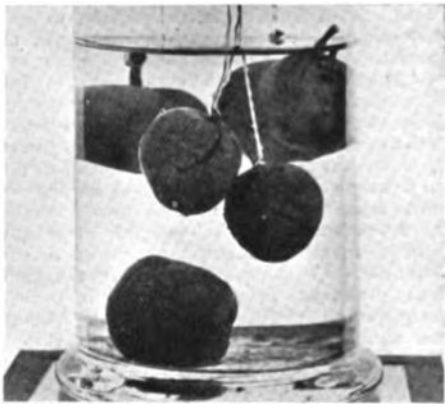
Burgundy mixture to check the spores from passing on to the wood and prevent a recurrence of the pest the next season.

Peach Leaf Curl.

The fungus disease which causes the peach and nectarine leaves to curl is very destructive during summer when peaches are grown out of doors. The leaves usually become distorted and curled and covered with white mould, later becoming pale green, gradually changing to a bright red colour. When the affected leaves are destroyed, the spores are conveyed by wind and other agents to neighbouring leaves and shoots and again cause stunted growth. The treatment which should be practised to control this disease is, first, collect and burn all distorted and curled leaves and tips of the shoots, cutting below where the leaves are destroyed. Then spray with

PEACH LEAVES MALFORMED BY LEAF CURL.

All parts attacked should be collected and burned.



THE UNSIGHTLY APPLE SCAB.

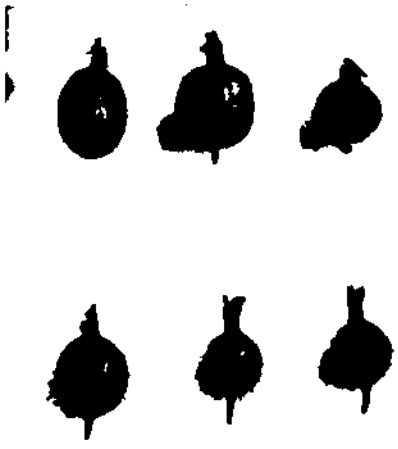
Note the cracks and corky scabs on the fruits. The trees should be sprayed with a weak solution of lime sulphur occasionally.

Coral Spot Disease.

The disease called coral spot is not confined to any one kind of fruit tree, for it can be seen on the wood of apple, pear, plum, gooseberry, red currant and many hard wood trees. The fungus lives chiefly on dead and decaying wood, but it sometimes becomes parasitic, *i.e.*, lives on growing wood. It is easily recognised in winter and spring by the bright red coral-like warts and in summer by the pale coloured pits in the decaying wood. Spraying with a fungicide is of little use in controlling coral spot disease, as it invades the wood and chokes up the water conducting tissues. Careful cutting out all decayed and decaying wood in winter and again during summer and painting the cut surfaces with tar will prevent it spreading to healthy wood.

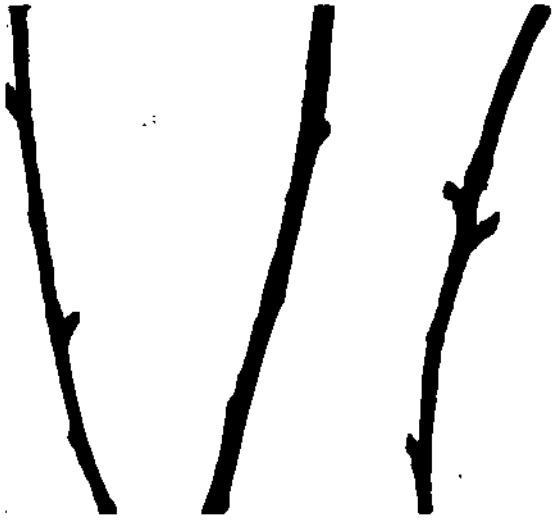
American Gooseberry Mildew.

The active stage in the life history of this disease is white and powdery and can be found on the leaves, shoots and fruit during the summer months. At this stage it spreads rapidly and can be carried by wind and other agencies. The inactive condition is brown in colour, which is really the dead mycelium with the spore cases embedded. To control this serious menace spraying should commence early in May and be continued once a fortnight until the middle of June, with the washing soda solution. Tipping should not commence until the month of August, for, if commenced too early, second growth will start and a late infection of the disease would be the result.



AMERICAN GOOSEBERRY MILDEW IN ITS ACTIVE STAGE.

Spray in early May with washing soda.



SHOOTS OF A PEAR TREE SUFFERING FROM THE EFFECTS OF PEAR SCAB.

Strawberry Mildew.

This disease is easily detected by the white mould on the under sides of the leaves and on the fruit, but is quite easily checked. It is more a seasonal trouble on strawberries. Royal Sovereign is very susceptible. When the leaves are affected they usually curl upwards, showing the white down on the under sides. The fruit is usually hard, pale in colour, and a very insipid taste. Dusting the plants early before the fruit sets will generally prevent the mildew from germinating on the fruit. Spraying the plants after the fruit is pulled will prevent a recurrence of the disease the following year. Amateur growers who spray with lime-sulphur and Burgundy washes would be well advised to procure them from firms who specialise in fungicides, rather than make up their own material, for both these washes are made commercially and are sold in handy tins and packets.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

MARCH, 1927, will be remembered by gardeners for its remarkable spell of summer weather. On several days in the middle of the month the day temperature in the shade registered 60°, and on the 21st ult. it reached a maximum of 63.9°. The effect of the genial atmosphere is to be seen in the premature appearance of foliage on shrub and tree, and more particularly in the flowering currant, which at the time of writing is in full bloom, and the leafage of the roses. The weather has, of course, favoured garden operations and tempted numerous amateurs to sow and plant subjects in advance of the usual time. If one may hazard an opinion based on present conditions, I would say that the season promises to be an early one, but in this uncertain climate and remembering the severe frosts experienced last year about May 20th, when widespread damage was done to the bush fruits, early potato crops, etc., Scottish gardeners would be well advised to err on the safe side and not run unnecessary risks by anticipating the normal season for sowing and planting.

The pruning of bedding roses, more particularly the varieties of the hybrid tea type, is a case in point. For some time past English writers have been advising their readers to cut back their trees in March, and in the diary of the Royal Horticultural Society an actual day (March 26th) is set on which operations are to be begun without any limitation as to locality or weather conditions. This is rather misleading and requires modification. The period specified may be all right for English growers, and particularly those resident south of the Thames, but it is much too early for rosarians in Scotland, who will find by experience that the middle of April is a more suitable time, and as the Easter holidays extend from the 15th to the 18th, they will find rose pruning a profitable occupation, provided, of course, that the weather is favourable.

While visiting a large private garden in Dumbartonshire the other day I was interested to find that the culinary peas under glass were as far forward as the sweet peas in the frames. The cultural system of raising an early crop of the popular vegetable was new to me, and a brief description may prove helpful to amateurs who possess a greenhouse. Instead of utilising boxes during germination and the early period of growth, the seeds were sown in rows running alongside the staging. The soil was encased in long strips of wood which formed the sides and bottom. These were arranged in sections of about 6ft., and to facilitate the transference of the earth and seedlings to the drills in the garden without disturbance string was used at intervals to keep the whole together. In the process of transplanting the string and bottom of the long narrow wooden structure are removed, and when the contents are fixed in their permanent position the sides are easily withdrawn. When watered beforehand the soil remains intact and the peas receive little or no check.

Catmint, which has come rapidly into favour as an edging to a mixed flower border, possesses many meritorious qualities which will appeal to amateurs. It is easy to propagate by cuttings taken in autumn, thrives in a sunny position in any good garden soil and takes precedence as a free-flowering hardy perennial. Moreover, the silver grey foliage makes a charming setting to the lavender blue flowers borne on erect stems and produced in great profusion over a long period of bloom, extending through the summer and well into autumn. Rooted cuttings that are planted in April will form a dense carpet in the coming season, and it may also be grown to advantage as small clumps in a rockery.

Another good edging plant for the amateur's garden is the pretty little marigold tagetes, whose rich shade of golden yellow seems to harmonise with any colour scheme. Being a hardy annual, the seed can be sown a month hence in the position where it is to flower in August and September, but earlier bloom may be obtained by sowing the seed now and raising the plants in a frame. The decorative qualities of the tagetes are not recognised to the extent that their merits deserve except by the plotholders in our city gardens, whose system of cultivating it in masses accentuates the brilliant colour effect.

Despite the advantages that are to be obtained by raising parsley in boxes in a frame and transplanting the seedlings in the same manner as culinary peas and exhibition onions and leeks, the custom of sowing the seed in shallow drills is still generally observed in small private gardens. To begin with the seed is sown too thickly, and as thinning out is seldom practised, the typical row becomes so overcrowded that the plants have not the room to develop, and should rust or other disease appear, it spreads rapidly along the row of these weakly plants. When properly grown parsley seedlings should be allowed a space of 6ins. between each, and in the case of plants raised under glass they combine the useful and the ornamental when grown 1 ft. apart in the border. Treated in that way the individual plants are almost equal in size and quality to pot-grown specimens, and provide a striking contrast to the drill-sown plants. Parsley transplants readily when the soil is in moist condition. ST. MUNGO.

PRACTICAL HINTS ON POTATO GROWING

WHEN the purchaser of seed potatoes receives the varieties ordered he should at once proceed to spread them out in a single layer in shallow boxes and place them in some room, shed or greenhouse with a moist temperature and a sufficiency of light.

For the first week they may be covered with a clean bag kept moist by an occasional spraying, but afterwards they should be placed in full light to induce thick sturdy shoots to form.

Meantime the plot of ground should be dug over two spades deep, and drills formed, 24ins. apart for first early, and from 30ins. to 36ins. for mid-season and late varieties.

The bottom of each drill should be freely dusted with "Alphol" or other good soil insecticide, then natural manure spread to a depth of 3ins. or 4ins. Stable or farmyard manure or, what is much to be preferred, hop manure, should be used.

Sufficient soil should be brought down from the sides of the drills to cover the manure an inch in depth.

The sprouted seed tubers, especially the new and more expensive varieties, can be with advantage cut into as many pieces as will leave two shoots to each piece. The cut face of the tubers must not be exposed to the air for more than a minute or two, but should be placed in the drill face downwards at from 12ins. to 18ins. apart, according to the varieties, and covered with 3ins. of soil on top of which a well balanced fertiliser should be sprinkled at the rate of 2 oz. to 3 oz. per square yard.

"Premier" garden manure or fish guano are equally good, but the latter is inclined to attract the neighbours' cats to the plot. Mixtures of sulphate of ammonia, superphosphate and potash

PLANTING POTATOES. THE DRILLS SHOULD BE ABOUT 30INS. APART AND THE TUBERS PLANTED AT A DISTANCE OF 12INS. TO 18INS. BETWEEN EACH.

Digitized by Google

salts can be made by the planter, but, unless well mixed in the proper proportions are liable to do more harm than good.

Later work in the plot consists of earthing up the plants as growth proceeds, giving with each earthing up an application of the chemical manures recommended above.

The potato is a gross feeder and loves an open porous soil; it is, therefore, essential that, until the final earthing up is given, the soil between the drills should be kept open by regular hoeing.

THE BEST POTATOES TO GROW.

The varieties to grow depend to some extent on soil and situation.

Of the older varieties on light and medium soils, Harbinger, Duke of York, Sharpe's Express, Witch Hill and Epicure can be thoroughly recommended for early crops of good quality. Great Scot, Majestic and King Edward for mid-season; Arran Victory, Kerr's Pink and Arran Chief for maincrops.

On heavy soils, Sharpe's Express, Eclipse, Ninetyfold and Immune Ashleaf for earlies; King George, Majestic, Great Scot and

SEFTON WONDER, AN IMMUNE HEAVY CROPPING VARIETY.

British Queen for mid-season; and Kerr's Pink, Tinwald Perfection, Golden Wonder, Factor and Field Marshal for maincrops.

New immune seedling potatoes are being raised and tested each season; very few of them are worthy of extended culture, but the following should be tried by all growers who can devote a little space and attention to them, especially as, by the purchase of a few pounds, a large supply of good seed can be obtained for the following season's planting:

Sefton Wonder.—A golden-skinned seedling from the universal favourite, Great Scot, with all the cropping qualities and upright growth of its parent combined with the flavour of the renowned Golden Wonder, whose only fault is its poor cropping capacity.

Catriona and *Arran Consul.*—Slightly older varieties with excellent reputations for cropping and exhibition purposes, but for table use not quite so good.

Tastes differ on the edible qualifications of potatoes. Some like them with a bite, some like them waxy, but the majority, I think, would vote for the variety that cooks like a ball of flower and does not discolour on exposure to the air.

Sefton Wonder is white and floury, with a most delicious flavour.

A SELECTION OF VEGETABLES

It is round about this date when most amateurs make their final selection of vegetables for this year's garden. Doubts and difficulties arise, as to what kinds to grow and which will be successful in light soil and which in heavy soil, and so on. These notes, giving a famous grower's selection of varieties of different kinds may prove helpful to the beginner. They are all tried and tested sorts which should succeed in all districts, but, as is pointed out, allowance must always be made for the situation of the garden. Varieties of vegetables which do well in your neighbourhood should certainly be given a trial.

"WHAT sorts of vegetables shall I grow?" is a question that faces almost every amateur gardener who attempts to grow vegetables each season as it comes round. And what a difficult question it often is to answer in these days when there is such a wide range of fine varieties from which to select. At the outset, however, it is as well to remember that there are two points to bear in mind, first, the preparation of the growing quarters, and second the finding out of just what varieties will attain success in your particular neighbourhood.

The first item is one that demands attention, for it is idle to expect even the finest of seeds to yield first-class results if the soil is not in good condition to afford the plant the proper root run that it requires in addition to having the soil in that condition which will provide the requisite food material and moisture.

Once again the writer would urge that deep trenching and inversion of the soil should be carried out at the due season, that is during late autumn and early winter to light, and late winter and early spring for tenacious and heavy soils. When the trenching is carried out, the provision of food material in the form of animal manure, where required, should be attended to, placing it at the bottom of the trench, so that the growing plant has to seek for its food. All details connected with the preparation of the soil should be carried out in the most workmanlike and skilled manner.

The effect of locality is of more importance than is yet realised, but it is now becoming well known that a variety of any vegetable that will yield excellent results in one area, will possibly prove quite a failure in an adjoining neighbourhood, and particularly is this the case with potatoes. Where varieties are mentioned those named have proved themselves excellent in the particular locality where grown by the writer. In view of this happening, it is well to urge the experimenting in small quantities with new varieties for a season, before making large plantings with it, especially in the case of high-priced novelties, to ascertain their possibilities and so avoid heavy loss that might conceivably arise.

I now give a descriptive list of a number of varieties of certain kinds of vegetables that have proved themselves excellent in all respects when grown at Aldenham, in Hertfordshire, under trying conditions of climate and soil, and which, in view of these conditions, may be likely to "turn up trumps" in the majority of gardens throughout the country.

Artichokes, Globe.—Grow Large French Green and Purple Globe, two forms well in advance of the older and inferior sorts.

Artichokes, Jerusalem.—Turn down the old forms, especially the inferior purple, and grow the improved New White, and, as another excellent and most distinct variety, try Fuseau, a French introduction of great merit, with long tubers.

Asparagus.—Connover's Colossal, Giant French and Perfection are all first-class, the latter being an improvement on Reading Giant.

Beans, Broad.—For longpod varieties, Leviathan, Exhibition Long Pod and Green Giant are to be recommended, while those who require the Windsor forms should try Giant Windsor and Green Windsor, for late sowings.

Beans, French (or Dwarf).—Of these there is a big selection, of which the choice is Magpie, Ne Plus Ultra, Canadian Wonder, Magnum Bonum and Satisfaction.

Beans, Climbing French.—Nothing to beat Tender and True.

Beans, Butter.—Golden Wonder, a stringless bean that can be cooked whole, and Parisian Delicacy are two excellent varieties.

Beans, Runner.—Of red-flowered varieties, select Prizewinner, Red Giant, Scarlet Emperor and Best of All, and of white-flowered sorts, Jubilee and White Monarch, as being all sterling varieties.

Beet, Long.—Out of the many varieties of good quality, the selection is for Dells (for medium sized roots), Pragnells Exhibition, Cheltenham Green Top (old, but excellent), and Covent Garden.

Beet, Globe.—Crimson Ball and Selected Globe.

Borecole or Kale.—From many forms, and what a variety there is, the choice should primarily rest on Victoria, as a Scotch curled variety; Cottager's Kale, the good old standby; and Labrador Kale, the most delicious of all, and which comes into use at a period when there is, nearly every season, a severe shortage of vegetable supplies.

Broccoli.—Self-protecting, Michaelmas White, Snow's Winter White, Christmas White, Leamington and Model for a late variety, and Purple Sprouting as a sprouting form. Nine Star is a new and very valuable addition.

Brussels Sprouts.—Dwarf Gem, for its fine "buttons," and Perfection should fill the bill.

Cabbage.—For sowing in March for autumn use, Winningstadt and All Heart. To sow in June for later use, Rosette Colewort and Hardy Green; and for the further batch, sowing in July and August to plant in the autumn, use Ellam's Early, April and Flower of Spring. As a red or pickling variety, Blood Red.

Carrots.—For early and late sowing, pits and frames, use Inimitable, Scarlet Champion Horn, followed by Model and Favourite, then New Red Intermediate (excellent for pits and outdoor sowing), and, finally, St. Valery and Long Surrey for the main, open sowings.

Cauliflowers.—Spring sowing, Early Giant, followed by Autumn Mammoth and Autumn Giant. For autumn sowing, Walcheren, Magnum Bonum and Snow Queen; selecting Early Forcing, Snowball and All the Year Round for mid-winter sowing and early forcing work.

Celery.—Nothing better than Aldenham White and Invincible White, with Standard Bearer, Giant Red and Aldenham Pink as red or pink varieties.

Cucumbers.—For summer supplies, Matchless, Ideal and Telegraph; for late autumn and winter, Lockies' Perfection; for winter use, Everyday; and for ridge varieties, King of the Ridge and Stockwood Ridge.

Endive, Batavian.—Improved Round-leaved Batavian.

Endive, Curled.—Model, Moss Curled, Incomparable, Green Curled and Winter Curled.

Digitized by Google

Leeks. — There is none to beat Improved Lyon, International and Prizetaker.

Lettuce, Cos.—For summer, Superb White and Mammoth White Cos; winter, Improved Brown Cos and Hicks Hardy White.

Lettuce, Cabbage. — For forcing, Golden Queen and Tom Thumb; for general use, All the Year Round, Perfect Gem, Marvel, Ideal and Hammersmith, the last named being about the hardiest of all for winter work.

Onions.—As main crops, Selected Ailsa Craig and Premier (one of the best); also James Long Keeping (still one of the most useful). For autumn sowing, White Leviathan, White Emperor, Blood Red Rocca and Lemon Rocca. For long keeping and general utility, Autumn Triumph, of excellent shape and colour, and longer keeping properties than any other known form. Silver Queen for special pickling properties.

Parsnips.—Tender and True, Student and Hollow Crown.

Peas.—For tall growers choose Early Giant and Edwin Beckett; with Laxtonian, Little Marvel and Giant Stride, a wonderful new pea, as dwarfs, for early crop. For second earlies, Duke of Albany, Alderman and Quite Content, and for late crops, Autocrat and Masterpiece. Remember to allow plenty of growing space in the rows, for some of the tall varieties, such as Quite Content, 10ins. from plant to plant is not too much to assist proper yield, and such varieties require good provision to do their best.

Potatoes.—Of these there is an enormous range, good, bad and indifferent, and it is difficult to make an exact choice owing to their differing behaviour in various neighbourhoods. A selection of varieties is given in another article in this issue.

Radish, Long. — Wood's Early Frame an easy first.

Radish, Short. — French Breakfast, The Sutton, Early Rose, White Olive, Forcing White and Forcing Carmine, are useful for all purposes.

Rhubarb.—Royal Albert, Myatt's Linnæus and Daw's Champion are all good for forcing, as well as general work; while Victoria, The Sutton, Hobday's Giant and The Streeter are all excellent for general purposes, the last named being a quite new and very fine introduction.

Savoys.—Perfection, Sugar Loaf (small), Drumhead (large), Dwarf Green Curled and Early Dwarf Ulm.

Spinach.—Victoria for general work and The Carter for spring and forcing purposes.

Tomatoes.—Red fruited: Sunrise or a selection from it; Perfection and Duke of York, with Winter Beauty for winter growing. Yellow fruited: Golden Perfection, Golden Sunrise and Sunbeam. For open growing, Sunrise, Golden Sunrise and Bides Recruit.

Turnips.—For frame work: Early Long Forcing, Early Red Milan, White Milan and Golden Sunrise (a yellow variety). For summer supplies: Jersey Lily, Snowball, Little Marvel, with Golden Ball as a yellow-fleshed variety. For winter use: Prizetaker, Chirk Castle and Black Stone.

Vegetable Marrows.—Moore's Cream (white), The Sutton (white), Perfection, a green variety and one of the very best for frame work, Tender and True, a fine green, bush form, Pen-y-Byd, a round, creamy-white and Table Dainty, an early cropping green that is undoubtedly one of the best marrows of to-day.

The foregoing is a fairly comprehensive list and in addition to the early cultural remarks it only remains to add that full care should be given during the growing period in the direction of thinning, hoeing and watering, feeding, where necessary, with liquid manure and reliable artificial fertilisers and success should be reaped in full measure for the careful, thoughtful grower. E. BECKETT.

GREENHOUSE NOTES

Greenhouse Flowers at Easter.

THE accompanying illustration shows a particularly well furnished small greenhouse, the plants employed being within the reach of anyone with an ordinary greenhouse and possibly a few cold frames, in which the primulas and cinerarias can be grown during the summer months, thus leaving the greenhouse free for a display of other flowering plants during the summer months.

The frames can also be used for the bulbs —in this case narcissi and hyacinths— during the winter, until such time as it is desired to introduce them to the greenhouse; although a cold frame (or frames) is not absolutely necessary, still where it can be managed it is a great asset for maintaining a succession of plants for the greenhouse.

Where it is desired to grow primulas for this purpose, they must be raised from seed every year; the varieties of Primula obconica should be sown at this time, sowing them in pots or pans of light rich soil, standing them in a greenhouse; they should be covered with a piece of glass and kept shaded until germination takes place. The many fine varieties of P. sinensis (Chinese primrose) are invaluable for the small greenhouse, the graceful and free-flowering stellata section being specially useful for decorative work. They may be sown from now until May, according to requirements. The graceful and beautiful P. malacoides, of which there are now many fine varieties, is ideal for the small greenhouse, and seed should be sown during June. They all respond to much the same treatment, that is, ordinary greenhouse conditions during their younger stages, and if they are available, cold frames during the summer months. Primula kewensis is also another beautiful and useful primula which should not be overlooked for our purpose, as it is just as easily raised from seed as the others. Cinerarias are also easily raised from seed, usually sown during June, but the time of sowing will vary according to individual requirements, the seed pots may be stood in cold frames, as the seed germinates freely at that time; during the summer they enjoy a cool, moist atmosphere and shade during the hottest part of the day. All bulbs should be purchased in early autumn and potted as soon as possible, thus giving them time to form plenty of roots, which is so essential for successful results with this class of plant. There are many fine varieties of narcissi, tulips and hyacinths suitable for this purpose. Freesias should always find a place as they succeed under perfectly cool treatment. There are many other plants that may readily be had in flower at this time, but space forbids the mention of them.—J. C.

PRIMULAS, CINERARIAS AND DAFFODILS IN AN AMATEUR'S GREENHOUSE.

For the Greenhouse Wall.

FOR clothing the back wall of a greenhouse or conservatory there is no better plant than the clinging Ficus repens, or stipulata, as the species is sometimes called. This plant has small roundish dark green leaves, and it will attach itself to any surface after the manner of ivy. In quite a short while it will cover a wall with a dense compact growth and, when once established, is an object of permanent beauty. Even in shaded positions F. repens does well, and it is one of the most accommodating plants. It is a good plan under glass to have F. repens planted in the ground, but where this cannot be arranged the roots may be in a pot or box placed at the base of the wall. Propagation may be carried out by layers or cuttings, but the latter should be of firm growths, the cut ends being allowed to dry somewhat before insertion. Until rooting takes place a close atmosphere is desirable. Always give plenty of moisture at the roots if quick growth is desired.—L. B.

Forced Daffodils After Flowering.

THERE is no reason why daffodils should be lost after they have been grown in pots or boxes by forcing; indeed, if a little care is exercised, the bulbs will be little the worse, if at all, for their period under glass. When the blooms fade, cut them off and stand the pot or box aside, but still in the sunshine; they may go immediately or soon into a frame, or even into the open, a warm sunny corner being selected and a frame sash thrown on top. Water must still be given, or an occasional dose of liquid manure, if the grower can spare time for that; the water supply has to be continued until the leaves turn yellow, after which pots and boxes may stand outside without further attention. Late in summer the bulbs are shaken out and planted, preferably in a rich piece of soil, where they will come up with little loss of their glory the following year.—H. A.

CHRYSANTHEMUMS FOR THE BORDER (see page 242).

APR 5 1927

THE

GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2889 Saturday, April 16th. 1927 Price TWOPENCE

A VASE OF MODERN VARIETIES OF CHRYSANTHEMUMS.

AMONG our late summer and autumn flowers there is none more popular than the chrysanthemum. Within recent years, the chrysanthemum has undergone considerable development and improvement, until there now exist countless varieties, showing a distinctive and wide range in both colour and form. Modern fashion in horticulture has selected the single varieties for special favour since they are lighter and more graceful in habit than the heavier mop-headed kinds, and thus are of more use for general decorative purposes, either indoors in vases or in pots in the greenhouse. In the open border they are especially useful, since they flower at a period when the majority of the real summer occupants are past their best. They are hardy, floriferous, of neat habit and of the most brilliant colourings, and when planted in clumps in the border provide a most effective display from late August until October. Planting can be carried out, provided the weather conditions are suitable, from the end of this month until the end of June. All amateurs should certainly plant a few of the up-to-date varieties to brighten the autumn border.

NOTES AND COMMENTS

Our Photographic Competition.

AS was announced in our columns in our last week's issue, it is our intention to run a photographic competition among our readers during the coming summer season in order to encourage garden photography and in turn to create personal interest in flowers and gardening. The competition will commence next month with our issue of May 7th, and will continue throughout the summer months when the garden display is at its best. Readers are invited to send in photographs illustrating some aspect of their own garden which they think will be of interest to other readers. It is our endeavour to make this competition serve a useful purpose in bringing together the various ideas of many of our readers and place them at the disposal of all. As is usual with all competitions, there are rules to be adhered to, but these are few, and it is to be hoped that all readers who are interested will send along photographs to make the competition serve a real practical purpose.

RULES.

1. All photographs sent in must be taken in the reader's own garden.
2. Each photograph should be printed on black and white paper. There are no restrictions against the inclusion of persons in the photographs. These often lend interest and instruction to the photograph by conveying an idea of the size of a plant.
3. There are no limits imposed as to size.
4. Photographs need not be mounted, and negatives must not be sent.
5. The name and address of the sender must be clearly written on the back of the photograph, together with a few particulars about the photograph, such as the name of flowers, where grown, when planted or sown and so on. These particulars, if given in full, will add considerably more interest to the photograph and to the competition.
6. Each photograph sent in must be accompanied by a coupon to be found on one of our pages, and a piece of cardboard should be placed in the envelope in which the print is sent to prevent damage in the post.
7. A stamped addressed envelope must accompany photographs sent in, for their return, if unsuitable If this rule is not complied with, prints will not be returned. Envelopes should be addressed to "The Editor," THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2, and marked "Photographic Competition" on the outside.
8. The Editor does not hold himself responsible for photographs lost or damaged in the post.
9. No correspondence will be entered into over this competition, and the Editor's decision is final.
10. All photographs published will become the property of THE GARDEN.

PRIZES.

For each photograph published five shillings will be paid, and for the best photograph of the week an additional sum of one guinea will be paid to the reader who sent this in.

All prizes will be paid on the seventh of the month following publication.

The first photographs in connection with the competition will be published in our issue of May 7th, and they can be sent to the above address from Tuesday next, April 19th. The coupon will be found on page xviii this week.

The Editor's Table.

ALTHOUGH as yet early in the season, we have received our first gift in the form of a fine collection of some of the newer varieties of lachenalias from Messrs. Barr and Sons of King Street, Covent Garden, W.C.2, along with a few spikes of their new golden yellow seedling freesia and some anemone blossoms, both single and double. The anemones especially are particularly charming in their brilliant and gorgeous colourings. The double flowers of A. coronaria La Brilliante are of a fine crimson lake to scarlet shade, while the single blooms of the variety His Excellency are of a glowing scarlet similar to the brilliant A. fulgens with the very effective sooty black cushion in the centre of the flowers, which makes for the most delightful contrast.

That there has been great progress made in the development of the lachenalia is fully illustrated by the many fine varieties sent by Messrs. Barr, many of which were shown last week at the R.H.S. Show. These new varieties show a decided advance both in colouring and size of flowers on the older forms like Nelsoni, Tricolor and luteola. The greenish colouring in these older types has been lost in the gradual evolutionary process, until now our present-day varieties are of good colouring, show a depth of substance in the flower and appear to be more vigorous in constitution. A few of the more striking varieties we have received are Thibet, with large flowers of a deep golden yellow tinged with green at the tips of the petals; Glow, of a pure deep golden yellow; Chaffinch, of a lemon yellow with an edging of maroon red to the petals; Pegu and Greenfinch, of a greenish yellow colour; and Siam, of a rich golden yellow.

This Week's Work

For Gardens in the South and Midlands.

Prick out into boxes annuals now in seed pans.
Finish pruning all roses, including tea roses.
Complete the sowing of hardy annuals, carrots, turnips, peas, onions, etc.
Plant out in rows peas raised in frames and onions raised in heat.
Sow greenhouse primulas and cinerarias in gentle heat.
Sow lawn grass seed and top-dress impoverished lawns.
Plant out bedding violas and pansies.
Take cuttings of fuchsias and Begonia Gloire de Lorraine.
Finish planting alpines, herbaceous perennials, climbers and gladioli.

This Week's Work

For Gardens in Scotland and the North.

Plant out sweet peas sown in February.
Top-dress rhododendrons.
Prune flowering currants when bloom is over.
Tomatoes may now be planted in a cold greenhouse.
Divide and replant Michaelmas daisies.
Plant montbretias 3ins. deep.
Finish rose pruning.
Sow culinary peas for successional crop.
Transplant lettuce in frames.
Make a later sowing of Golden Ball turnip.
Hoe growing crops on dry days.
Transplant when soil is moist.

Digitized by Google

CHRYSANTHEMUMS FOR THE BORDER

THIS class of chrysanthemum, after being neglected for many years, is now becoming increasingly popular, not only with market growers, who grow them in large quantities for supplies of cut flowers, but by all classes of garden lovers. This is not surprising when one considers how easy they are to grow, their long flowering season and the many purposes for which they may be used, not only for a supply of cut flowers but for affording a display in the garden during late summer and autumn, when along with dahlias, they do so much to brighten our gardens. Over the dahlia they have an immense advantage, from the fact that they are much hardier, standing, as they do, several degrees of frost without suffering any injury; in this respect some varieties are, of course, hardier than others. Important as they are to the market growers and for the embellishment of parks and gardens generally, they are also equally useful for the amateur or small garden owner, not only for furnishing a display in the garden but also for giving a supply of cut flower, or, if so desired, they may be grown in pots for furnishing the small and unheated greenhouse. Some of the later-flowering varieties are specially useful for this purpose, as they sometimes fail to develop their flowers properly in the open.

Assuming young plants have been propagated from cuttings during February or early March, they may—when hardened off—be planted out any time during April. If a piece of spare ground is available they should be planted out on it, and be grown there all summer. Where this can be managed it is a great advantage, as later on they can be lifted and used to replace early-flowering subjects that have finished flowering. They transplant readily, even when coming into flower. When it is desired to move them, they should have a thorough soaking at the roots the day previous. If they are planted firmly and well watered in they recover from the shift within a few days. Where there is no reserve garden, they must, of course, be planted out directly into their flowering quarters.

In their young state they must be pinched several times to induce a bushy habit, the amount of pinching required depending largely on the habit of the different varieties. Some of them are naturally of a bushy habit and throw up a succession of flowering shoots from the base of the plant. Flora, an old pompon variety, is an excellent example of this type of plant, and on this account is ideal for bedding purposes. Whatever their individual habit, three stoppings are usually enough for most of them.

Many of the varieties are quite hardy, especially on light, warm soils and in some cases may, if so desired, be left undisturbed for several years. When it is desired to replant or increase them this is best done during the spring, when they have made about 4ins. of growth. They may then be increased to any extent, as each shoot, as a rule, may be detached with roots all ready for replanting. Where no stocks exist, young plants ready for planting out may be purchased during April. Border chrysanthemums are not at all fastidious as regards soil, thriving, as they do, in any well cultivated garden soil.

Where it is desired to lift them for propagating purposes, or possibly to make room for planting bulbs and other spring-flowering plants during the autumn, when they have finished flowering the required number of stools should be lifted and packed in boxes, which may be stored in a cold frame for the winter. If no frame is available, they may, as a rule, be safely wintered at the foot of a sheltered wall.

Where it is desired to grow them for greenhouse decoration, one has the choice of two methods. They may be grown throughout in pots, or they may be grown in the reserve garden for the summer, when they may be lifted and placed in suitable sized pots. They should be cut round with a sharp spade a week or ten days before it is desired to lift them, giving them a good watering at the roots the day before lifting. They should then be kept shaded for several days until they get a hold at the root.

BORDER CHRYSANTHEMUMS IN A SUBURBAN GARDEN.
The clumps can be lifted, divided and replanted this month.

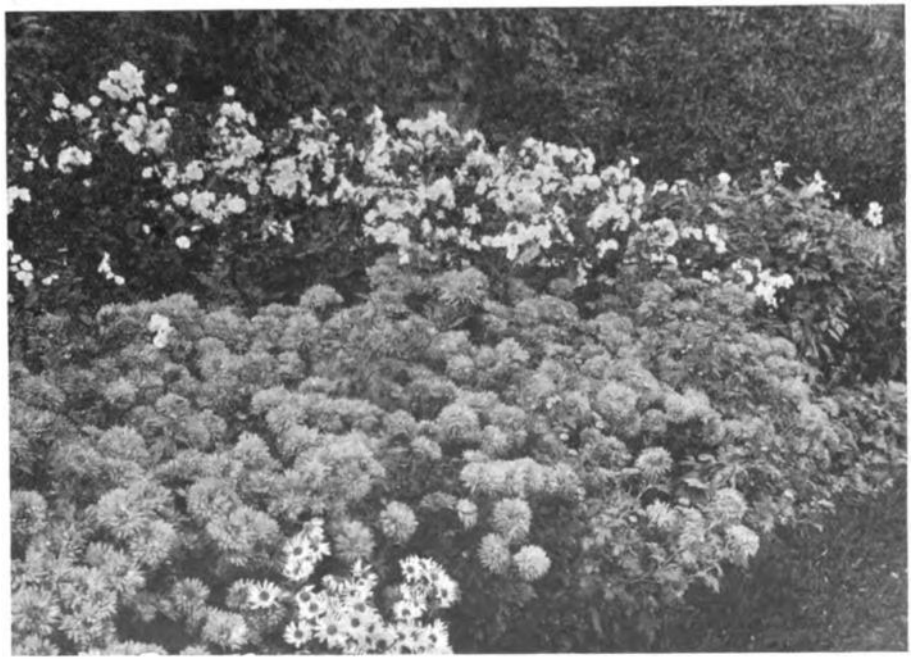
On the other hand they may be grown throughout in pots. In this case they must be potted firmly in a compost consisting of a good loam, with enough sand or old old mortar rubble to keep the whole open porous. To every bushel of compost should be added a five-inch potful of bone meal and a sprinkling of soot. After potting they should be stood closely together at the foot of a wall, where they should be sprayed frequently and carefully watered until well established at the root, when they should be stood in the open. If partly plunged in a bed of ashes it will keep them cool at the root and also save watering. They should be kept staked and neatly tied, as required. When they have well filled their pots with roots manure will be necessary at least twice a week, using for this purpose a good guano or some other approved fertiliser. Clear soot water is also very good for this purpose.

There are numerous varieties, but the following are a few of the standard sorts that are really worth growing.

Early-flowering pompons: Craigmillar, yellow; Flora, yellow; Little Bob, crimson; Piercy's Seedling, orange yellow; St. Crouts, light pink; and White St. Crouts.

Early-flowering Japanese varieties: Abercorn Beauty, terra-cotta; Crimson Polly, chestnut crimson; Dick Barnes, burgundy colour; Goacher's Crimson, bright crimson; Golden Diana, golden yellow; Harry Thorpe, golden yellow, shaded fawn; Normandie, pink; Sanctity, white; Almirante, bronze; Shirley Bronze; Knaresborough Yellow; Mrs. Jack Pearson, bronze, fine for cutting; Bronze Early Buttercup.

The following are fine October-flowering varieties for pot work: Blanche du Poitou, white; Primrose Poitou; Pluie d Argent, white; Uxbridge Bronze; Ethel Harvey, yellow; and Uxbridge Pink. J. C.



CHRYSANTHEMUMS IN THE EARLY AUTUMN BORDER.

RHODODENDRONS FOR THE ROCK GARDEN

EACH year more gardeners admire the dwarf rhododendrons that are often shown at the Royal Horticultural Society's shows during the spring months. As a rule, however, they admire these admirable plants from a distance and imagine that they require special soil and treatment. That is not the case; so long as the soil is lime-free, dwarf rhododendrons may be grown in almost any rock garden.

They like the same soil conditions as all other rhododendrons, a good porous soil with a certain amount of humus in it. Ample drainage is essential, and the soil must never be allowed to get bone dry. They must be planted in the same way as other species and hybrids, not too deep in the ground and with a mulch of old leaves, leaf-mould or peat-moss litter around them.

Shelter from wind is not such an important matter with these dwarfs; in fact, as most of them live on the hills of China as heather does on the Scottish moors, they are accustomed to constant wind. What is of importance is the amount of sunshine, for many of these Chinese moors are buried in clouds during many weeks of the summer, and so they should not be planted in positions that get full sunshine. There are, however, plenty of nooks in every rock garden that the sun only reaches for an hour or two every day; it may be a pocket among the rocks that is sheltered from the noon sun by a big stone, or a little ledge at the base of the rock garden proper that faces, preferably, to the west. An easterly exposure should be avoided if possible, for early sunshine after a frosty night in April may scorch the blooms, whereas afternoon sunshine will do no harm.

At the end of this article will be found a dozen useful dwarfs. Gardeners who have already dabbled in rhododendrons may complain that several admirable species, such as Rh. Williamsianum, are left out. There are, in fact, many wonderful dwarf plants that are not included in this list but most of them have one fault in the eyes of the gardener who does not specialise in rhododendrons; although small, several years must elapse before they flower. On the other hand, all the species in the list will flower in three or four years from seed, and of all of them plants 6ins. or so in height can now be purchased which will certainly produce some flower the year after planting.

It will be found that many of them are inclined to grow larger than they do on their native moorlands, and so become straggly in course of time. But this lankiness can easily be remedied by pinching or cutting off the tops of the longest shoots, which will make the plants much more bushy in appearance.

ONE OF THE BEST OF ALL DWARF RHODODENDRONS, RH. HIPPOPHÆOIDES, FOR THE SMALL GARDEN.

Another point to remember is that most of these species grow in as close formation as our heather, and it is always better to try to copy this form of growth by planting them in clumps. This can easily be done as they root excellently from cuttings taken from half-ripened wood inserted in sand in a frame. A fine batch of healthy young plants is soon formed by this method; or, if preferred, they can be raised from seed, which is very freely borne.

Such charming dwarf shrubs do these rhododendrons make that it is surprising that more use is not made of them in quite small rock gardens. They are attractive both in flower and in foliage through many months of the year; indeed, it is only from December to February that some of the species show a certain browning of the foliage, which must not be taken for ill health.

RH. INTRICATUM, A NEAT BUSHY GROWER WITH LAVENDER BLUE FLOWERS.

Rh. calostrotum (April), clear rose, flowers the size of half a crown and large for size of plant; grey-green foliage.

Rh. chryseum (March-April), pale yellow, forms a bushy little plant with tightly packed small flowers; the colour is good, though pale.

Rh ciliatum (April), palest pink, should certainly be grown in the open; if in shade the flowers open too early and are cut with frost. The buds are a deeper pink.

Rh. fastigiatum (April-May), deep lilac blue, has a greyish tinge to the leaves and in other respects is like R. impeditum.

Rh. ferrugineum (May), rose, the European alpine rose; should not be in full sun. Colour varies in various forms, and only the best should be grown.

Rh. hippophæoides (April-May), lavender blue, one of the best of all dwarfs. The best forms are a real blue. Grows slightly taller than many dwarfs and will reach 3-4ft. in time.

Rh. hirsutum (May), pink rose. Although often listed, this European dwarf is not really good in cultivation. The flowers are smaller than those of R. ferrugineum.

Rh. impeditum (April-May), deep lilac blue, a neat bushy little plant with deep green leaves. Very attractive and easy to grow.

Rh. intricatum (May and other months), deep lavender, another neat and bushy plant; when large will flower through many months of the year.

Rh. primulinum (April-May), pale yellow, very like Rh. chryseum in cultivation.

Rh. racemosum (April), pink, will reach 4ft. One of the most floriferous of all rhododendrons. Will grow in any position, and so a very useful plant.

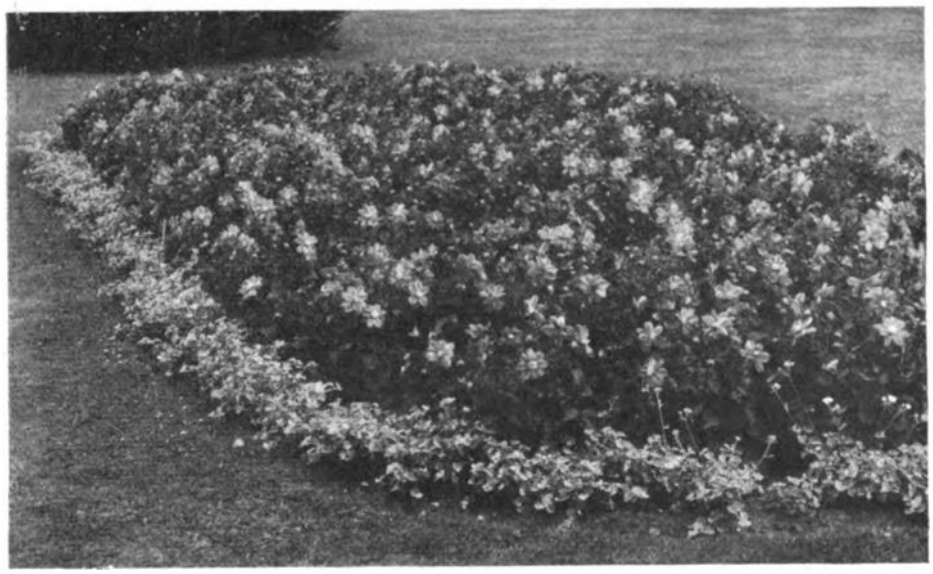
Rh. scintillans (April-May), lavender blue, is usually more bluey than intricatum and impeditum. A good plant, but not quite so easy to grow.

Digitized by Google

DAHLIAS FOR EVERY GARDEN

Modern dahlias are among the most beautiful and useful of all the late summer and autumn flowers, and their popularity is steadily and deservedly increasing every year.

GREAT improvements have been made by raisers since the time when dahlias were considered by most flower lovers—apart from florists and exhibitors—as heavy and rather ungainly subjects from the decorative standpoint out of doors, and almost useless as cut flowers. In all classes—and there are a large number of widely differing types and forms—the better varieties now are early and free flowering, with their blooms carried erect and well above the foliage on long, stout stems. Better habit of growth is not the only point in which improvement has taken place. For brilliance and diversity of colouring, few flowers can equal present-day dahlias, and the actual shape of the flowers is, on the whole, much more decorative and generally useful. It is not now an exhibitor's flower purely and simply, but one which fully conforms to the requirements of the average amateur gardener.



A BED OF THE BRILLIANT SCARLET COLTNESS GEM, ONE OF THE BEST OF ALL BEDDING DAHLIAS.

This variety is used extensively in our public parks and gardens for late summer bedding. An edging of a silvery foliaged plant like helichrysum provides a charming contrast.

CULTURE.

The successful culture of dahlias is quite a simple matter and presents no difficulties, even to the beginner. Although very accommodating as to soil and position, they prefer sunny and open situations and a deeply dug liberally manured soil. It is wise to prepare the ground some little time before planting, digging deeply and trenching, if possible, to a depth of 18ins. to 24ins., mixing in a good dressing of decayed animal manure. Dahlias are rather gross feeders, but too much manure of a nitrogenous nature should be avoided, for this has the tendency to produce superabundance of foliage. On soils inclined to be poor, the addition of bone-meal or fish-manure, as well as animal manure, is beneficial.

Dahlias are not hardy, and the time to plant them out of doors depends on the locality. The first or second week in May is quite early enough for the South and Midlands, and the first and second weeks in June for the north of England and Scotland respectively. The young plants—usually well rooted cuttings from pots—are delivered from the nurseries from the end of April to the end of May, and if it is not safe to transplant them out of doors, they should be potted up singly into small pots and grown along in a cool greenhouse or cold frame, gradually hardening them to outdoor conditions.

The distance apart at which they are planted out of doors will, naturally, depend on the height of the individual varieties. Dwarfs, such as the well known Coltness Gem, need no more ground space than 18ins. from plant to plant; while those which attain a height of 4ft. to 6ft. should be allowed 4ft. Apart from the dwarfs (which need no support except a short, thin stake at the outset), I find it a simple method to drive the centre stakes in, as a guide to position, before planting. Then plant out, and tie each one loosely to its own stake. Before proceeding with actual cultural methods, may I digress. It is usually found convenient to devote a whole bed or border to dahlias alone, and if the varieties and types are to be mixed, it will not be a waste of time carefully to arrange their positions, not only according to height, but in an order which will give a pleasing colour blending to the bed, taken as a whole. It is surprising what a difference a well arranged colour scheme will make in the general effect. Of course, when cut flowers for the home are the only consideration, there is little need for colour blending, and a corner of the kitchen garden will be found just as suitable a position for the plants as the flower borders. Slugs and snails are often a source of trouble immediately after transplanting, and if no precaution is taken against them, the whole batch may be quickly cleared. It is usually sufficient to make little rings or barriers of lime, soot or finely sifted ashes round each plant; but a further preventive measure is to sow lettuce seed on the dahlia site a short time before planting.

Growth will be slow for some weeks, and watering with soft water may be necessary in dry spells; but keep the surface of the soil from "crusting" by fairly frequent shallow hoeings. As soon as vigorous growth commences insert three more stakes round each plant, slightly slanting outwards. Two or three strands of thick string tied round these stakes will complete the supports; but side growths should be tied regularly as they grow outward, or strong winds may snap them off. Unless thought too unsightly, a surface mulch of strawy manure or Wakeley's Hop Manure applied round the base of the plants in the summer will conserve moisture. Some of the early-flowering types, the charms and dwarfs, are very precocious; I have often seen flowers on them when they were barely rooted as cuttings in the pots, and it will assist growth if such plants are disbudded for a short time until their roots are well established. At no time should seed pods be allowed to form, unless seed is required; all faded flowers should be removed. On most soils occasional watering will be essential in the late summer and early autumn, with an occasional application of liquid manure.

TYPES AND VARIETIES.

There are enough types and forms in present-day dahlias to fill nearly any position in the garden effectively, and to satisfy almost every taste. The exhibitor will find ample scope for his efforts in the exhibition cactus type with its symmetrically formed flowers. The average amateur, however, will find the coarse-petalled cactus or hybrid cactus more useful and better suited to his needs. As cut blooms for indoor decoration, the charms, in my opinion, are easily the most valuable class, with their exquisite semi-double, medium-sized flowers in all shades of colour. They have stems like wire and are extremely free flowering. The small decorative and collarettes also make effective cut blooms. For large indoor decorative schemes or displays, the peony-flowered type is superb, their large, but semi-double, irregularly shaped and somewhat loosely made flowers effectively counteracting their heavy appearance.

The dwarf or mignon dahlias are still more or less in their infancy, although the best-known dwarf variety, Coltness Gem, is by no means new. The sale of this little bedder is many times greater than that of any other dahlia in existence. Further improvement is certain in this type, and it will not surprise those who have seen some of the latest developments if dwarf dahlias become the most popular bedding subjects for late summer and autumn display. Planted in large beds in conjunction with the taller charm varieties and still higher-growing peony-flowered kinds, the effect is truly magnificent. These three types are undoubtedly the three most valuable for bedding purposes.

There are other classes, but those mentioned are the most popular, and I will give just a few reliable and inexpensive varieties which are typical of each type:

Charms.—Our Annie, shrimp pink; Dazzle, intense scarlet; Charmer, orange salmon; Gwynne, deep crimson.

Peony-flowered.—Old Gold, golden amber; Eunice, mauve; Albina, white; Enchantress, silvery pink.

Collarettes.—Gold Tip, scarlet edged gold; Doon, orange scarlet; Viola, yellow; Circe, lavender and white.

Garden Cactus.—F. W. Fellowes, orange Alabaster, white; Arthur Pickard, salmon pink; Patriot, crimson scarlet.

Decorative Cactus (coarse-petalled).—Fred Treseder, bright yellow; Lady Derby, soft lilac; Fireflame, scarlet; George Duncan, salmon rose.

Digitized by Google

Giant Decoratives.—Anak, crimson scarlet; Emblem, rose pink on yellow; Mrs. P. Palmer, purple; Sunray, yellow and scarlet.

Small Decoratives.—Raider, cinnamon; Rhoda, shrimp pink; Tipsy, scarlet; Carine, deep orange.

Pompons.—Bacchus, scarlet; Little Beeswing, yellow edged cherry red; Midget, salmon peach; Tommy Keith, cardinal red, tipped white.

Dwarfs.—Coltness Gem bright scarlet; Abinger Gem, bright orange; Amber Queen, ivory salmon or salmon buff; Golden Gleam, golden orange. The last two are 1927 novelties, as yet rather expensive, but with semi-double "charm" shaped flowers. These varieties are all excellent for bedding purposes.

C. H. A. S.

A CAMERA IN THE GARDEN

IF you want to photograph a growing plant your first problem is to devise some way of making it stand out clearly from its surroundings.

The camera has no discrimination. It does not just select out the particular plant you want to take and subdue everything else. If your subject's next-door neighbours are big strong-growing things *they* will probably appear as the most important item in the picture.

To avoid this you must in some way or other isolate the plant you want to photograph. You could, obviously, do this by clearing away anything growing too close to it, but that is not often desirable and would still leave the problem of a suitable background to be solved.

The simplest and most satisfactory plan is to put a screen behind and on each side of your subject. For small plants a large sheet of grey cardboard bent to shape is admirable—for larger plants, use an old blanket—or other natural tinted material—loosely hung over four or five canes which form a framework for it.

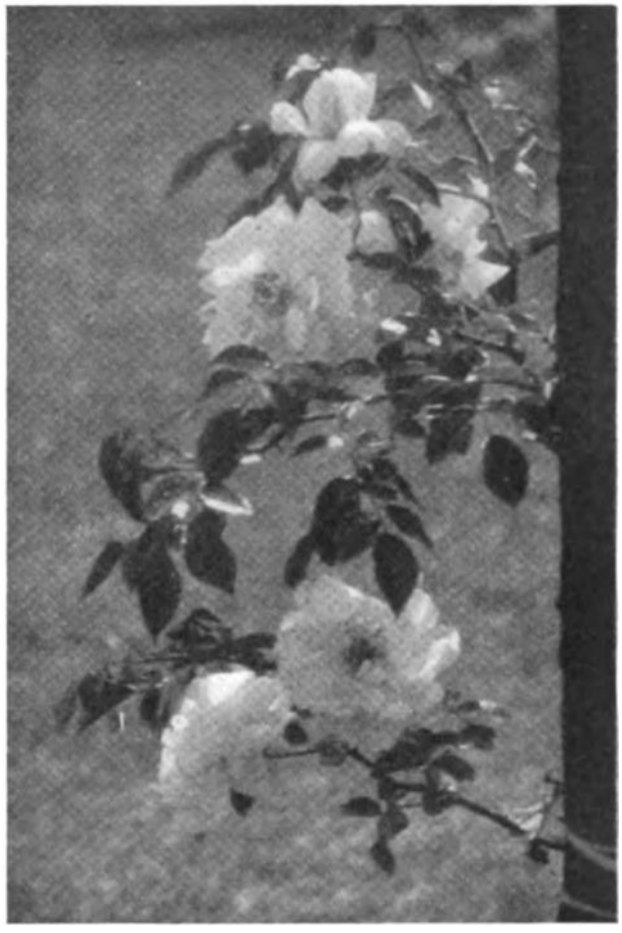
Having isolated your subject in this way you will find the rest of the work easy. The screen has the additional advantage of shielding the plant you are photographing from the wind—thereby cutting out one of the most fruitful sources of failure, for, to give a time exposure on a plant that is being swayed by the wind, is to make certain of a blurred result.

Be careful in your choice of lighting. Generally it should be from one side or the other and — once again—the low light of morning or evening is more helpful than the shadowless blaze of the midday sun.

The technical point of which you must be most careful is to *measure* the distance from camera to subject. There is little latitude in focussing at close quarters and guesswork will not do. You will, of course, need to use the focussing adjustment on your camera, or to slip a portrait attachment over the lens.

Perhaps the most fascinating branch of garden photography is the taking of individual flowers — or groups of flowers. These can be picked —so you can photograph them indoors or out as you think best.

As a rule *indoors* is better, because it gives you a greater control of the light and you will not be troubled by the wind, even on the most breezy day.



ROSE ALBERIC BARBIER.
A photograph taken with the light coming from behind the subject.

TO BRING OUT THE TRUE COLOURINGS OF FLOWERS PANCHROMATIC PLATES MUST BE USED.
In this photograph are roses of white, yellow, pink and crimson shades each of which can be easily distinguished even in black and white.

Remember, that many a bloom that would fail on the exhibition bench may look quite perfect in a photograph, because it is then seen from only one point of view —so that any fault can usually be hidden.

Do *not* place your subject too near the window — the light there is too harsh. Four or five feet away will be about right and then — with a large sheet of white card or paper, or a white towel, placed on the opposite side of your subject to the window, where it will reflect light into the shadows — you will get a delightfully soft lighting.

Here again accurate focussing is absolutely essential, if there is no focussing screen on your camera, you must *measure* the distance, not guess it.

Use a colour filter of course. The strength of light varies even more indoors than it does outside, so it is difficult to give even an approximate estimate of the exposure, but with your lens set at F. 16 or U.S. 16 something between half a minute and two minutes will probably be about right.

In the first article on this subject we saw that an ordinary film or plate is colour-blind, and that this defect can be minimised by the use of a colour-filter. This corrects the rendering of blues, greens and yellows—but red in its various shades is still rendered much too dark. To get a good rendering of red flowers—or even deep pink ones—you must use a panchromatic plate or film. This is specially sensitised and will render any coloured object in just the right tone in monochrome if a colour filter is used. You can get panchromatic plates or cut films, but *not* roll films or film packs. Being so sensitive to *red* they must not be developed in the ordinary darkroom light, but either in darkness (by the time method), or with a special safelight. Undoubtedly the use of panchromatics is worth the slight extra trouble involved.

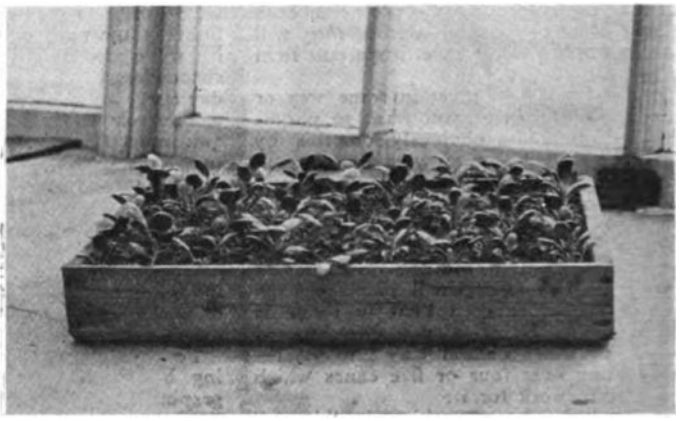
THE BUSY MAN'S PAGE

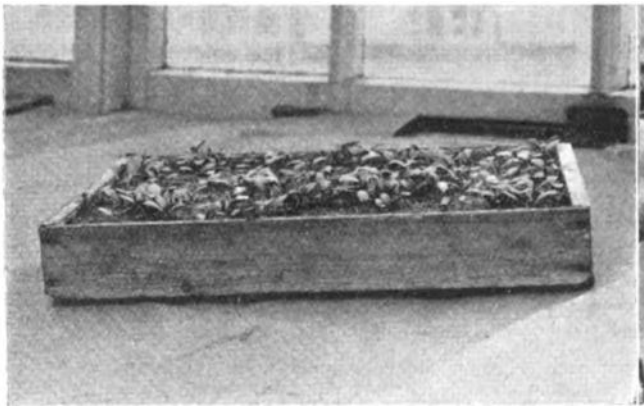
Pricking Off Half-Hardy Annuals.

WHEN the seedlings of the half-hardy annuals, such as asters, stocks, nemesias, phloxes, salpiglossis, zinnias, etc., have made a good start, it is most important not to defer their removal to boxes or pans, where they will have more room for development. Delay in this direction will mean that the young plants become drawn and weakened and in such a state they cannot be expected to give the best results. The time for removal has come when the little plants have formed another pair of leaves besides their seed leaves. The soil in the new receptacles should be in a friable but fairly moist condition. Set each little plant in right up to the seed leaves. Give a sprinkling of water through a fine rose after the replanting. For a few days shade from bright sunshine, and generally keep the plants near the glass and allow the freest possible ventilation. For most of the half-hardy annuals 2ins. apart is a good distance, although, in the case of the phloxes, which are strong growers, it is an advantage to allow an additional inch. The plants can remain in the new positions until they touch one another, by which time they will be ready for planting out in the garden.

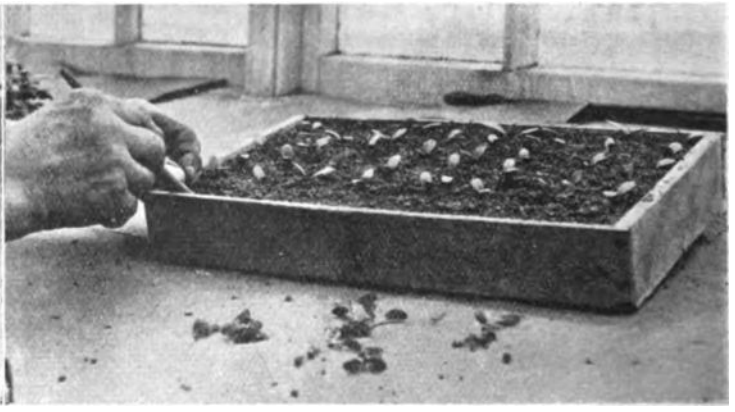
A box of salpiglossis seedlings which have been allowed to become drawn up and weakened.



Seedlings transferred to boxes at the proper time. The seedlings should be pricked off immediately their first leaves have formed.



A batch of seedlings of Phlox Drummondii ready for removal to another box.



Pricking off the seedlings. Note the distance of 2 to 3ins. left between each seedling, and the method of placing them in the box.

Liquid Manures.

A CERTAIN amount of harm may be done by giving liquid manures in an improper manner. These should never be given to any plants that are dry at the roots. Water first of all with clear water and then give time for this to drain away, finally employing the liquid fertiliser. By following this plan one ensures that the tiny roots of the plant will not be damaged by any caustic matter in the fertiliser. Generally speaking weak liquids, given frequently, are better than strong solutions applied at long intervals.

A Syringe Hint.

WHEN using a hand syringe to spray bushes with an oily or soapy mixture, it is often found that the barrel, which is sure to be wetted with the solution, is extremely difficult to hold. A firm grip of the syringe is essential if the required force to do the necessary work is to be developed. It is a very good plan to have a band of metal soldered round the barrel at the most convenient spot. A piece of ribbed brass raised ¼in. in the centre gives a secure hold. A simpler plan is to wind a length of thick copper wire tightly round the barrel and to hold this in place with a touch of solder. Such a job could be done by any metal worker for a trifling charge.

Summer-Flowering Stocks.

ALTHOUGH the summer-flowering or ten-week stocks are favourites in all parts of the country, one does not always find them as well grown as they ought to be. The plants must be grown without a check of any sort and, as a rule, too early sowing is to be avoided. As soon as possible the seedlings are to be transplanted into a box of loamy compost with some "body" in it, *i.e.*, not too porous, and the hardening off process may not begin until the plants are sturdy and well rooted. Sowings may be made now directly in the open border or in a seed bed. Above all must every grower get the very best of seed; even with it, there will be a certain percentage of singles, but, fortunately, the singles can be spotted quite early and, if a reserve stock is kept, replaced without loss. One of the best strains for cutting is the Perpetual Perfection Stock, which can be had in all colours. For immense spikes, full flowers and choice colours, there is the Giant Perfection. For garden bedding one may have the ordinary kinds or the Dwarf Large-flowering. Worthy of mention, too, are the Mammoth or Beauty Stocks, delightful plants for summer and autumn flowers.

Preventing Rust on Tools.

IT is a great mistake to allow any garden tools to become rusty as, in this state, they are less efficient and naturally, do not last so long. A simple way of preventing the coming of rust is on the following lines. Mix equal parts of paraffin and sweet oil and keep in a closely stoppered bottle. Free the tools from dirt and then wash with plain water, finally drying with a rag. When the metal is quite dry, rub it over with a piece of cotton waste which is kept moistened with the liquid in the bottle. Shake the bottle now and again when in use. This plan causes only a little trouble and is well worth while. For instance, a rusty spade or hoe collects earth so that the work is hampered, but this does not happen if the metal is bright.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

A Town Roof Garden.

IN the accompanying illustration of a roof garden, simplicity is the keynote of the design. Distant chimney stacks are effectively screened off by the use of an artistically designed trellis, against which a rose is starting to climb. On the coping of the wall are a couple of wooden boxes filled with box shrubs. In the corner a place is found for a tiny fountain and lily pool. This contains a single plant of Nymphæa pygmæa alba, a charming water-lily for the small water garden. The standard sweet bay adds scent to the atmosphere of the tiny roof garden. How often does one see a roof garden too crowded with pots and boxes often producing anything but a beautiful effect. In our large cities there are many flat roofs or balconies that could be treated simply and adorned with beautiful plants, such as is suggested in this example.

AN ATTRACTIVE ROOF GARDEN UNDER TOWN CONDITIONS.

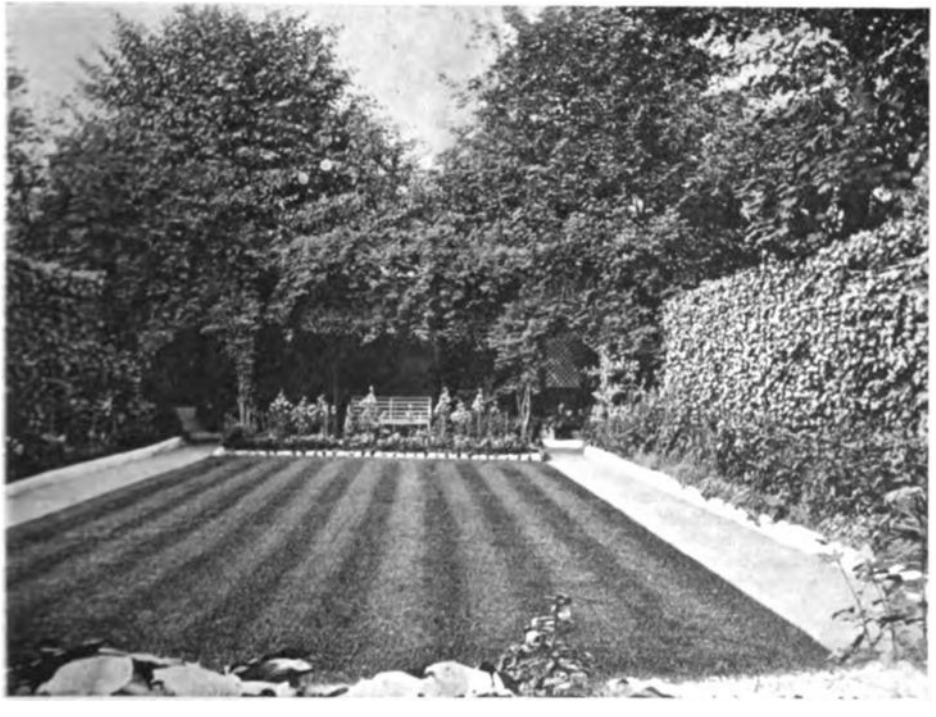
Making a New Lawn.

NOTHING sets off the beauty of summer flowers so well as a smooth green lawn. Even in a small garden, a patch of grass gives a cool and inviting appearance; and a large garden without grass is almost unthinkable. There is a popular belief that grass will not grow in town gardens, that is, in those gardens which come within the more congested areas. But what of the lovely grass patches near to the Government buildings in Bird Cage Walk? They are almost flawless in appearance. The lawn depicted on this page is only a mile or two from the heart of London, yet I doubt if a better kept patch of grass could be found anywhere in the country.

One of the essentials for a good lawn is the proper preparation of the ground before seed is sown. Turf, while it may make a lawn more rapidly, is not easily obtained in towns, and in the end is less satisfactory than growing the lawn from seed. Drainage is essential. A trench dug every 6yds. into which old bricks or clinkers are thrown, will provide good drainage if there is a tendency for water to remain on the surface. The surface must be levelled where necessary, and the whole area dug over to a depth of about 1ft.

It is false economy to buy cheap light seed. Good heavy seed, well cleaned so that it is free from weed seeds, is worth the price you are asked for it. Sow about 2 oz. to a square yard, sowing carefully and evenly, or the lawn will look patchy when it grows. Rake the seed in very lightly, only letting the rake teeth penetrate to a depth of ½in., so that the seed is not buried too deeply. Scatter a very little finely sifted soil over the surface, and pat it down with the back of a spade, or pass a roller lightly over it. The seed is very much liked by sparrows, and unless you protect it in some way you may lose so much that the lawn is a failure. A few short wooden pegs on each side, with black cotton stretched across and across between them, keep the birds away. Black cotton is used because the birds do not see it, and when flying down to peck at the seed, they come in contact with the strands.

Moisture is needed to enable the seeds to germinate, and should excessively dry weather follow the seed sowing, watering would aid germination, if the lawn is small enough to permit this to be done. When the grass is about 2ins. high, the roller may again be used, provided it is a light one which will not do too much damage to the tender shoots. The first cutting should be done either with a scythe, shears or a sickle; but in a very short time the mower may safely be used.



A PERFECT STRETCH OF LAWN IS A GREAT ASSET TO A SMALL GARDEN.
Attention should be given now to renovation and upkeep.

Treatment of Indoor Bulbs after Flowering.

REMEMBER that even when the flowers of indoor bulbs have faded, the roots still require water. It is a good plan to remove the plants from the bowls or pots and replant them in an odd corner of the garden, where they will ripen naturally. When the tops are dead, the bulbs can be lifted and stored until the autumn. If you have no garden, let the bulbs die off in the pots.

Bulbs of tulips, hyacinths and daffodils will bloom a second year if reasonable care is taken to ripen them off properly.

The Town Gardening Handbook.—This volume, the official handbook of the London Gardens Guild, is now published, and is obtainable from all booksellers and newsagents. The price is, cloth covers 2s. 6d., paper covers 1s. 6d. It is the one book for all amateurs who garden in town and suburb.

NOTES ON THE FLOWER GARDEN

Some Dwarf Perennial Asters and Their Uses.

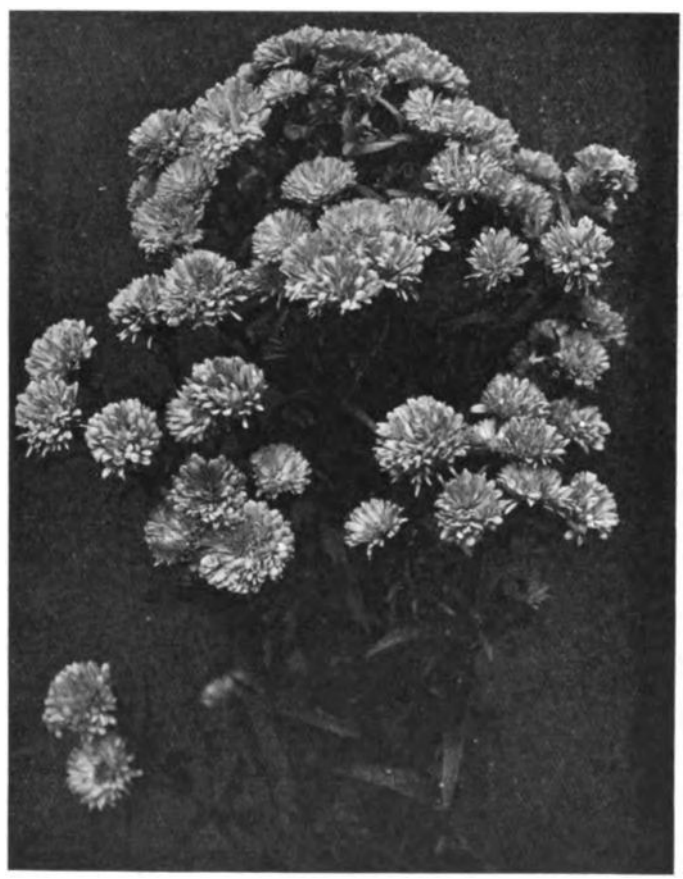
THE dwarf-growing Michaelmas daisies, such as A. Amellus and its varieties and some few others, lend themselves to a variety of uses, more so, perhaps, than do the taller Novæ-Angliæ and Novi Belgii sections; they are particularly pleasing when used for autumn bedding schemes and some beautifully blended effects are obtainable.

The species, A. Amellus, came from Italy so long ago as 1596 and is quite a good border plant, about 2ft. in height and with numerous purple flowers in August; its earliest recorded variety was possibly A. A. bessarabicus, still a very desirable plant, with larger flowers than the type and of the same rich shade of purplish-blue. It is a good subject for the border, for beds or for the large rock garden. Some select modern Amellus varieties are Beauty of Ronsdorf, 2ft., large lilac-pink; King George, perhaps the best of this section with very large violet-blue flowers; Rudolph Goethe, very similar to the last-named, but of rather stronger growth and an especially fine plant for furnishing beds; Framfieldii, reddish-purple thread-like ray florets, 2ft., late flowering; Little Gem, 1ft. high, flowering September-October, and a very fine plant for the rock garden; Perle Rose, very pretty dwarf form of clear rose colouring; Perry's Favourite, very fine rose-pink; Preziosa, deep clear blue, one of the finest in the section; Queen Mary, large light blue, and Riverslea, rich violet.

Except in very bleak situations, these asters do not require support, a fact which enhances their value for planting in the forefront of the hardy flower border, in isolated beds or in shrubbery borders; some very effective and decidedly pretty schemes are realised by planting the blue shades in company with yellow or bronze chrysanthemums. It will, of course, be necessary to chose a "mum" which is a floral contemporary of the aster selected.

From the Novi Belgii section of asters, I cannot forbear to mention Little Blue Boy and its pink flowered counterpart, Little Pink Lady; these delightful plants are characterised by stiff spire-like growth, some 2ft. in height and are literally covered, in September, with myriads of, respectively, bright blue and deep pink semi-double flowers; a remarkably pretty autumn display is the result of planting a flower bed with Little Blue Boy and an orange coloured chrysanthemum, such as Harvester, or a "mum" of deeper colour, as Nina Blick, may be used. The colour harmony is striking yet delightfully soft and pleasing.

Easter will not be too late to plant these hardy flowers and, indeed, my experience points to excellent results obtained from April planting.—R. E. A.



ASTER LITTLE BLUE BOY, ONE OF THE BEST OF THE DWARF MICHAELMAS DAISIES.

It has bright blue buttonlike flowers. This variety makes an admirable companion to its counterpart, Little Pink Lady, whose colour is a rich deep pink.

Nasturtiums.

THE homely nasturtium, so easily grown and yet so pretty, is one of the very useful border annuals favoured by all gardeners. The dwarfs are employed as dot plants in among the bedding flowers; they are used in designs or grown merely for flowers or foliage, or they may be freely grown to fill some doubtful corner. The creeping kinds are equally fine for covering a trellis or an old root or an unsightly mound, their exuberant streamers and plenteous foliage forming a delightful screen, enhanced by the half-hidden flowers. Now every grower must realise that harsh conditions suit these plants best, in the main. Do not manure the soil for them; do not, unless in the seedling stage, supply water; plant them in the full glare of the sun—and the plants flower with a profuseness as astounding as it is pleasing. Creeping kinds grown for a screen mainly are, however, more luxuriant in a rich soil. Seeds may be sown directly in the soil, now or soon; but before sowing, tramp the soil as firm as possible; of course, seedlings may be raised in the frame, too, but seedling nasturtiums are much hardier than most realise and than the behaviour of plants during frost in autumn leads one to suppose. Every catalogue has a selection of varieties, sufficiently described, and intending growers will spend a pleasant half-hour perusing the details. Let me, however, mention the newer Lilliputs, dwarfs among the dwarf kinds, neat, tiny, bushy plants of delightful nature. I grew Delight, Snow Queen, Red Ensign and Ruby last year, instead of the usual edging, along with lobelia, and the Scots saying that "Changes are lightsome" was fully justified.—LANARKSHIRE.

Two Good Geums.

TWO of the showiest and most persistent in bloom of all hardy border plants are Geum Mrs. Bradshaw and G. Lady Stratheden. The former produces a wealth of large, dazzling scarlet double flowers throughout the summer—flowers which rival in intensity of colour the flaming Cardinal Lobelia itself. Lady Stratheden is the golden yellow counterpart of Mrs. Bradshaw, and though quite a recent introduction, is becoming equally popular among discriminating gardeners.

Besides their value in the flower border these geums should be extensively grown where flowers for indoor decoration are required, for they possess two valuable attributes—long life in the cut state, and great grace of poise. They may also be planted in small lawn beds; as they are of perennial duration, these geums are particularly useful in this respect, and need not be disturbed until the flowers begin to dwindle in size, usually after three or four years' growth in the same spot. By planting early-flowering bulbs in the same bed, a bright display may be had over a long period, and at the very minimum of cost and trouble.

Seedling geums may be bought quite cheaply from advertisers in this paper, and they will flower profusely from June until September. Seed may also be sown under glass during the next week or so, and plants from this sowing will flower in late summer. From seed sown in April or May, fine sturdy seedlings will result for planting out in autumn, though these can scarcely be expected to flower during the present year.

For the best possible results, geums should be grown in rich moist soil and in a sunny part of the garden. In a very dry spot, the flowers will be of a good size at first, but gradually become smaller and smaller, until finally the plants are not worth garden room. Flowers on old plants also dwindle in size after the first three years or so. In this case, vigour will be restored if the clumps are divided up, though many people make a practice of raising fresh stock every two years and discard all the old plants when the new seedlings reach flowering size.

As regards the positions in which to plant, Mrs. Bradshaw never looks so well as when placed against a background of Michaelmas daisies or other late-flowering plants whose bright, green foliage will provide a pleasing foil for the brilliant scarlet blossoms. The yellow form is more easily placed, but will look best among flowers of a blue, scarlet or purple shade. Neither of these geums exceeds a height of 18ins., so a position in the fore part of the border is essential.—B. D. S.

The Willow Herb.

THIS is a rampant grower which certainly ought not to be introduced to a border of choice herbaceous subjects, but, nevertheless, its beauty warrants it a place in any odd corner of the garden which is partially shaded. Other waste places will occur to the observant, and although the epilobiums

Digitized by Google

thrive in a more or less boggy situation, they will also succeed in dry, stony soil and even in ashes. A bold clump of E. angustifolium is an attractive sight, with the stout stems some 5ft. or 6ft. high swaying in the breeze, at the apex of which are clusters of rosy red flowers. There is also a white form known as album. This plant is at its best from June till August, and a distinct feature of this willow herb is the myriads of seed vessels that follow the flowering period. Although these are wafted about with the wind, I have never found more than a few isolated seedlings anywhere near the parent plants.

Planted in a place where it can grow at will this delightful rose bay or willow herb will be an enjoyable feature and, moreover, it will never require further attention, being quite capable of taking care of itself.—B.

Annual Climbers for Summer Decoration.

AMONG the annual creepers and climbers will be found a few plants that will produce a wonderful array of bloom in a short time, and, moreover, hide many an odd corner during the summer months. The pretty yellow canary creeper is always attractive and if given a position facing south, with the necessary supports, it will be quite a feature during the summer months. The common tropæolum or nasturtium is well known and few climbers can excel it in brilliance or floriferousness. To achieve the latter, however, a poor rooting medium is required. Both these creepers can be raised from seeds sown in the open about April, or raised in pots and planted in their final stations in May. The convolvulus major section are ideal for covering trelliswork and the fronts of verandas. They can be obtained in a variety of colours, are quick growing and will thrive in any sunny position. Perhaps the choicest of this group is Ipomæa rubro-cœrulea Heavenly Blue, particularly the early-flowering hybrids. The large flowers are a beautiful sky blue, they are at their best in the morning, and for this reason the plant is known as the Morning Glory. It will be necessary to raise the plants under glass, thoroughly harden off, and plant out in a sunny, hot place at the end of May.

A QUICK-GROWING ANNUAL CLIMBER FOR HOUSE WALLS, IPOMŒA RUBRO-CÆRULEA.

In Cobæa scandens we have a less showy plant, but it is exceptionally free growing and, given a mild winter, it will survive and do well the following year. To get plenty of bloom the first year outside the seeds must be sown early to secure fine strong plants by May. A south aspect is preferable, and a liberal amount of space should be allowed.

A rarely seen but handsome climber is Lophospermum scandens. It will attain a height of 10ft. or more, and its large pink flowers are exceedingly attractive. Although it is readily raised from seeds, it is a good plan to root a few cuttings in the autumn and keep them in a frost-proof pit or frame till the following season.

Maurandya Barclayana is usually considered a greenhouse climber, but if the seeds are sown early under glass, the plants will flower freely outside if given a warm situation. A suitable place is on the rock garden where the slender growths could drape a large stone, and here the blue flowers would be seen to advantage.

Eccremocarpus scaber is a delightful climber not met with as often as its merits deserve, and although termed half-hardy it will withstand an ordinary winter in the southern and westerly parts of England. It succeeds best on a wall with a south or south-west aspect. Here it will grow freely, and produces its sprays of orange-scarlet blossoms throughout the summer months. It grows about 10ft. high, and if seedlings are raised under glass and planted out in May, flowers may reasonably be expected this year.—CHEPSTOW.

The Sand Myrtle.

THERE is no more delightful little evergreen shrub for the rock garden, the front of a mixed border, or for associating with heaths than the sand myrtle (Leiophyllum buxifolium). This is a native of eastern North America, and, though it is one of the ericaceæ and allied to the heaths, it is nearer akin to the ledums. It makes a twiggy, neatly rounded bush, usually under 1ft. in height. The slender stems are amply furnished with small oval leaves, leathery in texture and a dark glossy green. In spring, bud clusters appear at the ends of the branches, and these, being a bright rosy red, the little shrub is at this stage singularly attractive. The buds expand towards the approach of summer, breaking into a galaxy of pink-flushed, crystal white flowers, which are so numerous that they almost smother the foliage with the rosy foam of petals and prominent stamens.

The sand myrtle is perfectly hardy and easy in any fairly light well drained, lime-free loam, but it will prosper in sandy peat and may be given a little leaf-mould where the soil is poor and liable to dry out in summer. Propagation can be carried out by short, half-ripened cuttings struck in sandy peat during the later summer, preferably with gentle bottom heat. Young plants will often begin blooming when but 2–3ins. high. This interesting, comely little shrub is comparatively uncommon in gardens, which is odd considering its excellent qualities and easy culture.—A. T. J.

A Free-Flowering Trailer, Gypsophila repens.

TO maintain the beauty of the rock garden as long as possible should be the aim of every grower, and G. repens will furnish its quota of bloom after the bulk of the alpines have passed their best. This easily grown plant is a first-rate trailer, and admirably suited for hanging over large stones; while for the wall garden such subjects are well-nigh indispensable. It makes long trailing growths which are covered with a host of small white flowers from June till August. It will succeed

GYPSOPHILA REPENS, A LATE BLOOMING TRAILER FOR THE ROCKERY WALL.

in either full sunshine or partial shade and can be increased by seeds, cuttings or layers. When the cuttings or layers have formed roots they should either be potted up or transferred to their final stations, as they do not readily transplant from the open ground.

There is a variety known as rosea which is similar to the type excepting the flowers are rose colour instead of white. This form should certainly be grown. Another variety is monstrosa, which is larger than the type in all its parts, and consequently not so elegant. However, it is well worth growing.

Although gypsophilas enjoy a chalky root run, they will succeed in ordinary well drained soil providing the position is not shaded to any great extent.—T. W. B.

The Bog Arum for a Damp Position.

ONE of the most attractive subjects for a really damp position where something like bog or marsh conditions can be maintained is the bog arum (Calla palustris). This species is sometimes grown as a water plant in Britain, but it much prefers a moist position in the soil. The plant has a curious trailing habit and produces an abundance of pretty little spathes of the same colour as the well known arum lily. If the position in which the plant is growing is somewhat shaded, the bog arum produces larger flowers and leaves than it does in a more open situation. The plant is, however, perfectly at home in a position that is fully exposed, and here it will rapidly carpet the ground with its small dark green leaves. The result is very pleasing, and still more so when the white flowers crop up here and there along the creeping stems, each one only raised a little above the leaves. Like many accommodating plants the bog arum is often rather badly treated, but it is only at its best when growing in soil that has been enriched with leaf-mould and well rotted manure. This species flowers in the summer and increases with great rapidity by means of its running stems. The average height of the plant is between 3ins. and 8ins., but in shaded positions the latter figure is often exceeded.—S. L. B.

SAFEGUARD YOUR FRUIT CROP

From now onwards it is most important to keep a careful look-out for the appearance of insect pests on fruit trees and bushes, so that the necessary remedial measures can at once be undertaken. In the following article a number of the more prevalent pests are described so that the amateur will readily recognise the trouble and be able to counteract it by means of one or other of the suggested remedies.

AGAINST insect pests that threaten the fruit trees and bushes the gardener must wage merciless war.

However thorough the winter washing, grease-banding, etc., it is certain that some pests will have escaped, while there is always the very real danger of hordes of others swarming the trees from ill-tended orchards in the neighbourhood.

Sometimes the gardener can cope with these by hand-picking and trapping, but generally he must resort to spring or summer spraying if the trees and crops are to escape damage.

When spraying is done intelligently, and appropriate washes for the particular pests troublesome are applied at the right time, there need be little fear of failure. But carried out carelessly, with no clear idea of what is required, it will prove wasteful and ineffective.

Among the most destructive pests are the caterpillars of various moths—the green "looper" caterpillars of winter and March moths, tortrix moth caterpillars (which wriggle backwards if touched in front), black and yellow striped magpie moth caterpillars and the green and spotted grubs of the gooseberry sawfly; to mention but a few. All, by chewing the leaves, shoots or fruits are capable of doing serious harm and no tree is altogether immune from attack.

With handy sized trees, odd half hours can be profitably spent "hand picking" the caterpillars, matted leaves being opened and the "catch" dropped into a jar of insecticide or paraffin. When this is not practicable the trees must be sprayed with a poison wash.

Use a nozzle that will give the finest spray and coat every leaf and shoot with a film of poison, so that caterpillars and other "biting" pests, like weevils, etc., receive a poisonous breakfast.

Arsenate of lead is a powerful "stomach poison" wash to use against this class of pest. Buy it ready made from a reputable firm and water it down according to directions. Usually, half a pound of paste makes ten gallons of wash. It should not, however, be sprayed on fruit to be picked within a month of the application, nor should it drip on to vegetables growing beneath the trees.

Trees likely to be infested with caterpillars, etc., are best sprayed just before blossoming time and again when the petals have fallen. But never spray with any insecticide when blossoms are open, for fear of killing bees and insects busy pollinating.

For use near the date when fruit is to be gathered, a wash that quickly loses its poisonous properties should be chosen. Hellebore wash—prepared by dissolving 4oz. of freshly ground hellebore in four gallons of water serves this purpose well. Or, the hellebore powder may be dusted on the bushes while foliage is still moist with dew.

The codling moth pest, which causes the nuisance of "maggoty" or "worm-eaten" apples, will be checked if the trees are sprayed with arsenate of lead *immediately* after blossoming. Also, bands of sacking or hay tied round the tree trunk in June, will entrap the maggots searching for a hiding place; the bands being removed and burned in autumn.

It is very easy to confuse codling moth damage with that caused by the apple sawfly. Caterpillars of both burrow into and spoil apples, but since remedial measures are distinct, accurate identification is important.

Note that the sawfly caterpillar enters the apple by a hole in the side, eats out a cavity in the flesh and leaves through the side of the apple; whereas the codling moth caterpillar invariably enters through the *eye*, tunnels into the core, afterwards burrowing out through the side. Moreover, the codling moth caterpillar is slender, coloured and has eight pairs of legs, whereas the sawfly caterpillar is plump, white and has ten pairs of legs.

Spraying and banding, so effective against the codling moth, is of no avail against the sawfly, the remedies for which are to collect and burn fallen fruit, to run fowls under the trees in May and June, and to keep the soil hoed throughout the summer.

"Stomach poison" insecticides are useless

INSECT PESTS OF FRUIT TREES AND THEIR REMEDIES.

Pest.	*Fruit Attacked.*	*Symptoms.*	*Remedy.*
Caterpillars, grubs, weevils, etc., that chew leaves, shoots or fruit.	All fruit trees.	Bitten leaves, defoliated shoots, scarred fruit.	Spray with lead arsenate. Use non-poisonous wash, or Hellebore within month of gathering crop.
All aphides, "greenfly," "blight," etc.	All fruit trees.	Curled, blistered leaves, distorted growth, deformed stunted fruit.	Spray with "contact" wash before and after blossoming. *Before leaves curl.*
Codling Moth ..	Apple ..	"Maggoty" apples, damaged "eye" and tunnelled core of apple. Fruit dropping	(*a*) Spray with lead arsenate immediately after blossoming. (*b*) tie sacking band round tree trunk in June, burn in autumn.
Apple Sawfly ..	Apple ..	"Maggoty" apples, fruit dropping.	(*a*) Collect fallen fruit. (*b*) Run fowls under trees in May-June. (*c*) Keep hoe going under trees.
Magpie Moth and Gooseberry Sawfly.	Currant, gooseberry.	Defoliated shoots ..	Spray with lead arsenate after flowering. Use hellebore if within month of gathering.
Woolly Aphis or American Blight.	Apple ..	White woolly patches of "blight" on branches.	(*a*) Paint patches with methylated spirit. (*b*) Spray with "contact" wash.
Apple Sucker.. ..	Apple ..	Dead flower trusses, stunted foliage.	Spray with nicotine before and after blossoming.
Capsid Bug	Apple ..	Spotted foliage, stunted growth, scarred fruit.	Spray with nicotine before and after blossoming.
Apple Blossom Weevil	Apple ..	Blossoms "capped" with dead, unopened petals.	(*a*) Collect and burn "capped" blooms. (*b*) Tie sacking band round tree trunk in May; examine monthly and kill hiding weevils.
Red Spider	All trees, indoors and out.	Foliage sickly or rusty in appearance.	(*a*) Forcibly syringe with clear or soapy water. (*b*) Spray with paraffin-nicotine wash.
Pear Midge	Pear ..	Distorted fruitlets, pears dropping early.	(*a*) Burn fallen fruit. (*b*) Run fowls under trees in May-June. (*c*) Hoe soil throughout summer.
Mussel and Oyster Scale.	Apple, pear, plum.	Scales clustered on bark, weakened growth.	Spray with paraffin-nicotine wash in May.
Soft Brown Scale ..	Peach, currant, gooseberry	Blister-like scales on bark, weakly growth.	Spray with paraffin-nicotine wash in May.
Raspberry Moth ..	Raspberry ..	Cane growth wilting and dying.	Cut out and burn attacked canes in spring and summer.
Raspberry Beetle ..	Raspberry ..	Damaged flowers, maggoty berries.	Shake canes over cloth in spring, destroy beetles caught. Hoe round canes in spring.
Currant Clearwing or Bud Moth.	Currant ..	Buds and shoots dying, in spring.	Cut off and burn attacked shoots.
Strawberry Beetle ..	Strawberry ..	Berries bitten and hollowed out.	Trap in jars baited with meat sunk in ground among plants.

Digitized by Google

against aphides—the so-called "blight" and "greenfly"—that curls the leaves and stunts growth and fruit of apples, pears, plums, cherries, currants and gooseberries and the like. This type of pest feeds and does harm by sucking the sap from the tissues. Their food cannot be poisoned as with the "chewing" caterpillars and weevils, etc., and a wash that kills insects by *actual contact* with them must be employed.

There are many efficient and ready-for-use "contact" washes to be had—such as the "Katakilla," "Abol," "XL ALL" brands, etc., and a timely application of one or other of these will safeguard the trees.

AN APPLE SPUR ATTACKED BY WOOLLY APHIS OR AMERICAN BLIGHT, AND MUSSEL SCALE.
Note the appearance of the branches. (*Slightly enlarged.*)

SPRAYING MUST BE TIMELY.

Once leaves are curled, the chance of stemming an attack by spraying is a very small one. Watch closely and spray at the very outset of an attack; or before and after blossoming as a precautionary measure.

Use a coarse nozzle, spray with force and wet the under side as well as the upper surface of leaves and shoots; for every insect must be *hit*.

When the currant bushes are infested with "blight," so that leaves are rosetted and curled, it is a good plan to dip "bendable" shoots into a jar of insecticide—for no spray will penetrate to the aphides.

For those who like to prepare their own "contact" washes—not always a good plan in the long run, nowadays—a nicotine-soap wash is simple to make and sure in effect. The recipe is: Nicotine (95 per cent. pure), 1½oz.; soft soap, 2lb.; water, 20 gallons. Dissolve the soap in a little hot water, stir in the nicotine, add the remainder of the water and churn thoroughly.

This wash, besides being effective against "blight" is deadly to young caterpillars, etc., and applied to trees immediately before or after blossoming, is of great general value.

Other recipes for "contact" washes are:

Paraffin Emulsion.—Paraffin oil, 2½ pints; soft soap, ½lb.; water, 10 gallons. Dissolve the soap in a little hot water, add the paraffin and the rest of the water and churn thoroughly, for twenty minutes or so, with a garden syringe or bundle of twigs.

Quassia Wash.—Quassia chips, ½lb.; soft soap, ½lb.; water, 10 gallons. Steep the chips in water for twenty-four hours, strain the liquid into the dissolved soap and mix together. Use at once.

The pestilent woolly aphis or American blight on apple trees may be controlled by spraying with a "contact" wash, though branches within reach are best treated by rubbing over each white woolly patch with a brush dipped in methylated spirit.

As a remedy for the apple sucker and capsid bug pests—which are damaging apple trees in many gardens—the nicotine soap wash is effective, if applied immediately before and after blossoming. These two pests are not difficult to distinguish. The apple sucker, a small, flattish, yellow insect, attacks the bloom trusses, which remain on the tree dead and brown, *just as though cut by frost*. Foliage may also be affected. The capsid bugs, which are something like "greenfly" to look at, but much more active when disturbed, cause leaf spotting, stunted growth and disfigured fruit; attacked apples being patched with russety scars and lumps.

If the bark of apple, pear or plum trees is infested with the mussel scale pest, the tiny mussel-shaped scales harbouring the feeding and breeding insects, this unhealthy state may be remedied by spraying in May with a paraffin-nicotine wash, made by adding 1½oz. of nicotine to each 20 gallons of paraffin emulsion. Also, certain proprietary brands of "contact" washes will, as advertised, clear off this pest.

The soft brown scale, looking like brown blisters, on peach, gooseberry and currant branches, may be destroyed by this wash, which is also a remedy for red spider. In the greenhouse and with some outdoor trees, however, a means of preventing red spider damage is to syringe the foliage forcibly at frequent intervals with clear or soapy water.

Possibly the gardener may find much of his apple blossom "capped" with dead, unopened petals. The apple blossom weevil is responsible for this damage and, sheltering beneath each "cap" of petals is a small, pinkish grub, the culprit. Spraying offers no control of this serious pest. Every "capped" bloom must be picked off—by the stalk—and burned. The weevils may be trapped in a band of sacking tied round the tree trunk in late May; the bands being examined monthly and hiding weevils destroyed.

Wholesale dropping of pears when about the size of marbles generally signifies the presence of the pear midge pest. Fruitlets attacked by the midges are usually deformed, with sooty patches on the skin; inside each being several dirty coloured maggots in a mass of rotten pulp. Here, again, spraying offers no control, remedial measures being to collect and burn abnormal fruits, to keep the soil hoed and where possible to run fowls under the trees in May and June. Also, kainit forked into the soil in June has proved a deterrent and a help to the trees.

In some gardens the raspberry beetle and raspberry moth prove serious pests. The beetles lay eggs on the flowers from which grubs hatch to spoil berries. Trapping is the only remedy, the canes being shaken over a cloth or paper and dislodged beetles destroyed.

The reddish grubs of the raspberry moth, which eat out buds and cause growths to wilt are best dealt with by burning canes attacked. Loganberries also suffer from the attentions of these pests.

Similarly, caterpillars of the currant clearwing or bud moth, which tunnel into and kill young shoots, should be destroyed by burning attacked shoots in spring.

The beetles that bite and hollow out the colouring strawberries should be trapped in jars baited with meat and sunk to the rim in the ground about the plants. These beetles, beneficial at other seasons, should be taken to another part of the garden and set free.

It is generally recognised that the "big bud" pest of black currants is controllable by hand picking in February and by lime-sulphur spraying when new leaves are the size of a shilling piece. Spraying in late spring with a "contact" wash, or sulphur powder dusting, may possibly do some good, but cannot be confidently recommended.

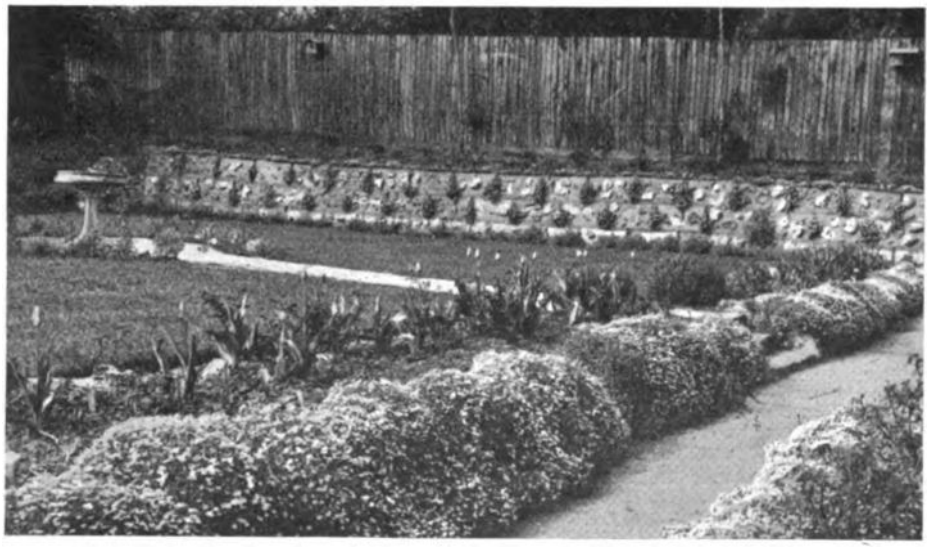
MAKING A CEMENT BLOCK RETAINING WALL

An interesting job which many amateurs may like to try. This article, by one of our readers who has constructed in his own garden the wall illustrated, gives full particulars as to how it may be carried out.

THERE is no occasion to explain why this cement wall became necessary, beyond saying that a bank of soil of very poor quality was left after levelling a sloping site for the lawn. This, when the toe of the sloping bank was cut away, left a straight face some 4ft. in height which required some mechanical support to keep the remaining soil from falling down. Presuming that the necessity for such a wall exists, the first thing to do is to measure the length and height of the proposed erection. This will give a rough estimate of the number of blocks which will be required to cover the area, due allowance being made for 2in. spaces between the blocks when laying, for the introduction of flowering plants. For ease in handling the blocks should measure 18ins. by 12ins. by 3ins. in thickness.

THE SOIL BANK BEFORE THE WALL WAS MADE.



THE WALL AND THE SUNK GARDEN PHOTOGRAPHED A YEAR AFTER THE ABOVE ILLUSTRATION.

A mathematically minded constructor would make one block, and calculate from the amount used the quantities of material required for the whole wall. My method was to commence with one bag of cement and a load of rough, sharp sand, from which I made blocks until the cement was exhausted. A bucket of cement will make four blocks when mixed with the sand and other "ingredients."

Sand is expensive, and many other cheaper ingredients can be mixed with it to form the blocks. Mine consisted of the rubbish which can be found lying about most newly constructed houses—broken brickbats, old bottles, broken drainpipes, tiles, jam pots, crushed tins, or rusty wire netting—the latter making a very strong block if roughly hammered or compressed into the shape of the block. Coke, cinders and small stones also economise the use of sand.

The shape of my blocks would have horrified a builder, for some were true rectangles, while others were geometrical nightmares. This was due to the fact that I moulded my materials by means of planks pegged into a gravel path. Such irregular blocks are extremely difficult to lay, and I would recommend making the moulds from hinged pieces of wood cut to the required sizes, in order that each block may be symmetrical in shape and size. The hinged boards will make removal easy when the block has set hard. At least three such moulds should be made. They consist simply of two pieces of wood measuring 18ins. by 3ins.; and two to form the ends, 12ins. by 3ins. These are hinged to form rectanglar sides without top or bottom.

The stock mixture of cement and rough sand should be made in the proportions of cement 1 part, sand 5 parts. A bucket makes a very good measure for this purpose. Place the cement and sand in a deep wheelbarrow, and thoroughly incorporate by mixing with a spade while in the dry condition. Then pour in a bucket of water and mix again, adding more water, if required, until the whole attains the consistency of freshly dropped cow-dung. The economy ingredients are added to this stock mixture in the following manner: Place the moulds on a hard gravel path, or piece of soil which has been levelled and rammed hard. In the bottom place a layer of small stones, cinders, brickbats or other "ingredient" until the mould is half full. On this pour or shovel the wet stock misture, paddling it about until it has found its way between the crevices of the stones or other material which has been placed in the mould. If a plain-surfaced block is not required, nearly fill the mould, then press into the wet surface large flints or other stones. It is the top surface which will be the face of the finished block. The displacement by these stones will bring the cement level to the top of the boards, which can then be left for at least a day to set roughly. The hinged boards may be removed the day after making, as this hastens the drying of the block; but do not attempt to remove the blocks for at least four days. Then gently lever them from their contact with the ground (it will be found that they have become very firmly fixed to the earth or gravel) by means of a crowbar or the sharp end of a pickaxe. Once their contact with the ground has been broken, they are easily lifted and set on end to become thoroughly hard. For the first four days they must be treated with respect, for they are only partially set, and somewhat liable to break under rough treatment.

So much for the manufacture of the slabs. Now comes the business of laying them in place. To make a thoroughly sound job, a narrow trench, 6ins. wide by 3ins. deep, should be cut in the position to be occupied by the foot of the wall. In this put a couple of inches of the stock cement mixture before each block is laid; then bed the slab in the cement—of course, laying the blocks by mean of a garden line in order to keep it straight. Leave a 2in. space, and repeat the operation until the whole of the first row is in position. The laying of the first row presents no difficulty, and should be allowed to set in position before further rows are added. The second and subsequent rows are laid by placing an inch of the cement stock mixture on the upper edge of the lower slab by means of a builder's trowel. Then gently press on to this one of the half-blocks (necessary for the completion of this row, and obtained by making a whole block and cutting in half when partially set; this can be done with a spade if the block is made entirely of cement and sand, without the admixture of ingredients). Neatly point off the surplus cement mixture which will squeeze out of the block when laid, and continue with the rest of the whole blocks. Allow this row to set for at

THE METHOD OF LAYING THE BLOCKS.
Note the cavities behind the spaces between the blocks for insertion of the plants and good soil.

THE COMPLETED WALL.
The plants are inserted between the spaces but are too small to show up in the illustration.

least a day before adding another line, and so on. The second row will, of course, be completed with one of the half-blocks.

The amateur will find that the placing in position of one row measuring 8oft. will be as much as can be managed at one time. Should it be intended to put plants in the spaces between the blocks, the roots should be inserted as the wall goes up, covering with soil at these positions. When the whole of the wall has set firmly in position, there will be spaces behind the rows of blocks which must be filled with earth. This should be sifted and in a friable condition, so that it will pack closely behind the back of the wall. It is not advisable to ram this soil, or the cement may crack at the joints if not thoroughly hard set. If the soil at the back of the wall is poor, this is the time to add enough good compost to ensure a good send-off for the plants. It is an easy matter to determine where the spaces between the blocks will come before they are laid, and large pockets of the poor earth can be removed at these stations, filling with a good soil or compost after the block has been laid, and the plant put in position.

The top edge of such a wall is not particularly attractive, and may be hidden by planting good-sized plants along and close to it. These at once break the hard and continuous line, and give a more pleasing effect than when left without any covering.

The percolations of water from the back of the wall, rapidly remove all traces of the cement appearance from the face of the blocks, giving them an effect similar to that of weathered stone. Those who object to the even tone given by such a wall can vary the colour of the blocks by mixing in a proportion of deep yellow sand, or ochre, or even green distemper, when making the stock mixture of cement. As, however, the wall soon loses this even grey appearance, this is only an unnecessary operation.

CLARENCE PONTING.

WHAT OUR READERS SAY

AN AMATEUR'S CROP OF AILSA CRAIG ONION.

SIR,—I am always interested in THE GARDEN and like to read your correspondents' experiences. Perhaps they may like to see the fine crop of Ailsa Craig Onion I gathered last year. As an amateur I am vain enough to think they are good. The seed was sown in the open in March and the seedlings thinned out later on in the year.—A. C., *Sundridge*.

PLANTS IN AN ANGLESEY GARDEN.

SIR,—Owing to the mildness of the climate in this island, many tender plants can easily be grown without any danger of them not surviving the winter season.

In a certain garden on the north coast a Chanthus puniceus about 8ft. to 9ft. high, growing on the wall of the house, may even now, in these early days of April, be seen beginning to bloom and will soon be a mass of coral, claw-like flowers. By its side, farther down the wall, is a tender species of acacia, also showing a mass of yellow, fluffy, globula flowers, this, which in some counties, is carefully guarded in the greenhouse, here blooms gaily out of doors.

The olearias, of which there is a beautiful specimen of chatamica, the Myrtus bullata and the metrosideros have survived the winter climate with perfect hardiness.

This may prove of interest to readers of THE GARDEN, in so much that it shows how perfectly these Chilian and New Zealand shrubs thrive in our climate.—M. W. H.

DELPHINIUMS FROM SEED.

SIR,—I sowed some delphinium seed last August in a box. It came up very thickly. I left the box standing on ashes out of doors till the end of January, when I brought it into a cold house. As the little leaves began to show I pricked the seedlings off into boxes; they were strong little plants with masses of roots. I have given away hundreds.

A FINE CROP OF ONION AILSA CRAIG, GROWN BY A READER LAST YEAR.

I now have large numbers of fine little plants ready shortly to be put into the open border, I think big enough to be fairly safe from slugs. This is the first time I have tried this plan and the first time I have had any success with seedling delphiniums. They have always been devoured by slugs, whatever precautions I may take; but I think that sowing so thickly and leaving them undisturbed through the winter has produced too many seedlings for the slugs to tackle, and they do not seem to have suffered from overcrowding. When I was pricking them out the roots were a solid mat several inches long and had to be carefully separated.—M. F. HARRISON *Iron Acton, Glos.*

PROPAGATION OF LONICERA NITIDA.

SIR,—I have had some experience of propagating this plant, which I think may be useful to other readers of THE GARDEN. When the hedge is clipped, mid-March is a suitable time, all the trimmings may be set in a narrow trench in shade facing north. Last year I had 100 per cent. success with this treatment, every trimming rooting. No preparation of the cuttings was made whatever. When I was lucky enough to obtain my first clippings, I adopted the treatment mentioned in your note in the issue of THE GARDEN for March 26th. With that

Digitized by Google

batch I lost over 50 per cent. of the cuttings through failure to strike. This season, owing to lack of space in which to put out rows, I have dug a hole, put in an armful of trimmings with the severed end down, and heaped soil over this end. I have very little doubt that quite 60 per cent. will root.—P. A. HENDLEY, *Cambridge*.

OSMANTHUS DELAVAYI.

SIR,—I was much interested in the note about Osmanthus Delavayi, as there is a plant here which is just over 6ft. high and forms a dense bush 9ft. in diameter. It would be larger only that it is growing by the edge of a path and has to be severely cut back every year at one side. In some cases it is, therefore, rather large for a small rock garden. The plant is now covered with blossom, and has been out since the middle of March. On account of flowering so early, it sometimes gets injured by frost. So far, I have been unable to get cuttings to strike.—S. S. PARKER-HUTCHINSON, *Nenagh*.

JOBS FOR THE HANDYMAN

Seed Bed Protectors.

A REAL business-like seed-bed protector is shown by Fig. 1. The arrangement consists of two wooden ends shaped as in either view A or B, Fig. 2, which are pushed into the ground, one at each end of the bed. Small tacks are driven round the edge, and strong black thread is linked round the tacks and extends over the seed bed.

Quite a good idea is to fix a reel of thread on one end by means of a screw, allowing for the reel to turn; the thread may then be wound off the reel as required (see Fig. 1). The wooden ends detailed in view A and B Fig. 2 will be found a useful size, and when made they should be coated with creosote.

When the arrangement is not required the thread is re-wound on the reel, and the ends are taken from the ground and laid up for future use.—W. J. S.

About Seed Trays and Plant Boxes.

MILLIONS of special boxes are made each season for the raising of seeds and for the pricking off of the resultant seedlings. The greater number are made of varying depths, but of the standard superficial dimensions, 15ins. by 9ins. There are obvious advantages in having all these boxes (or "trays") the same size; they pack together better, and are more convenient for fitting to shelving. The amateur, however, often presses into service all kinds of confectioners' or even soap boxes; and most of them need a certain amount of reconstruction before they are fitted for plant growth. Some steps must, for instance, be taken to ensure drainage. The bottom boards of the proper seed-trays are spaced a quarter of an inch or so apart, but few amateurs will want to take to pieces any "spoil" obtained from the confectioner if this may be avoided. A few good-sized holes drilled with a brace-and-bit will serve equally well for drainage; or the holes may be burnt in with a red-hot iron bar or old poker.

The professional gardener makes little trouble about getting his plants from the boxes, and with their roots intact, but the novice is liable to wreak havoc in his endeavours to get the plants out safely without damaging the box. A little trouble at the time the boxes are being assembled or overhauled will overcome this difficulty. Let us suppose the box to be complete as regards ends and bottom and one side. Now, instead of nailing on the last strip, take two strips of sheet iron or tin plate about 4½ins. longer than the depth of the box and about 1½ins. wide—old cocoa tins will provide suitable material, and fold over the sharp edges on both sides as at A (Fig. 1). Now turn the box upside down and affix the strips as in Fig. 2, leaving in each case a bare couple of inches along the bottom edge of the box, and nailing securely down. (The nails, will, of course, go through into the stout ends of the box.) Turn the box over again so that it is now right side up, and the right-hand corner will appear as at A in Fig. 3. Place the missing board in position, and draw the straps up over it as at B; pull tight and nail down, as at C. The box (Fig. 4) is now ready to be filled with compost, and it will be found that the strapped side is quite secure while the plants are in growth. It will nevertheless be quite easy to slide back and withdraw the board when it is desired to transplant the contents. The method of strapping described is suitable only for comparatively shallow trays. Where deeper boxes are in question—as for raising lilies or onions from seed—a slightly different method of fixing should be adopted. This is shown in Fig. 5; and it will be seen that the side board is slotted for a length rather more than twice the thickness of the end board and to a width of about ⅛in. Strips of tinplate are fastened centrally to the end board by a not too thick, but fairly long screw, and drawn upwards and downwards over the slotted board in the way already described. The long slot need only be made in one end of the board; a slot *one* end-board-thickness long will answer at the other. The long slot may easily be stopped as the box is being filled with a little rough compost, or a piece of old label; but some amateurs who use this device suspend a small piece of tin plate to cover this hole by a single tack over its centre. The tin then pivots when the side is withdrawn and is in position to be used again.—MIDLANDER.

POTATO CULTURE IN SCOTLAND

Practical Hints for Amateurs

AS the time for planting potatoes is regulated by what may be termed the three S's—soil, season and situation—no definite period can be allotted for this important branch of garden work. Raisers of first early sorts who have a portion of a sheltered border at their disposal endeavour to get the seed put in as early in March as possible—and the genial weather experienced this year has certainly favoured operations out of doors—while April is observed as the general planting period for those specimens of the mid-season and main crop groups which in small gardens and allotments constitute the principal source of household supplies up to the end of the year. The planting of late potatoes, however, is not restricted to April, and in view of the fact that the crops mature about the end of September excellent results may be obtained by planting the tubers any time in May.

There is probably no other garden vegetable which is influenced so much by soil conditions as the potato. The table quality varies in a marked degree. It may be good in one locality and poor in another, and even in neighbouring gardens the distinction is noticeable. This characteristic is particularly prominent in The Ally, one of the heaviest cropping varieties in cultivation. It is one of Mr. McKelvie's Arran productions, but its cooking qualities are negligible when grown in its native soil. When grown in Ayrshire and other parts of Scotland where it was tried experimentally, a slight to moderate improvement was obtained, but it was in England that the best results were obtained, and these no doubt explain the present popularity of the Ally in the south. It is therefore difficult to say which variety will do best in individual gardens, and the best advice one can give is to grow only the sorts which are suited to the soil.

This may not seem helpful to the amateur who was satisfied with the quality and abundance of the crops of British Queen and Arran Chief, two once popular potatoes that are now banned by law in gardens and allotments owing to their susceptibility to wart disease. As a matter of fact, all non-immune varieties are included in the prohibition order which is sometimes honoured in the breach more than the observance by a class of gardeners who prefer to run the risk of being found out rather than play the game. To those readers residing in scheduled areas I would say, try as a substitute for the second earlies specified Catriona, a kidney-shaped tuber with purple eyes, and one that has an excellent reputation as a big cropper and good cooker. Probably it may not be obtainable so late in the season in certain localities, and in that case Great Scot or Arran Comrade may be chosen. Then as a main crop potato a selection may be made from The Bishop, a good all-round variety for exhibition or household use, Kerr's Pink, Roderick Dhu and Golden Wonder. I consider that the latter is the finest potato in commerce, and good reports have reached me regarding Incomer, a new main crop tuber, oval in shape.

Various methods of planting garden potatoes are favoured by amateurs. One of these is quite contrary to the recognised modern theory which condemns the planting of seed tubers on ground that has recently received a heavy dressing of fresh organic manure. According to expert opinion, this treatment depreciates the quality of the crop and renders it more liable to disease. Theory and practice, however, are not always in agreement, and in this particular case ample proof is to be found in many country districts in Scotland where the old-fashioned system of planting seed potatoes on green manure placed in the bottom of the drills is attended with excellent results, both as regards the quantity and quality of the crop. At a meeting of a Glasgow horticultural society lately Mr. Joseph Dobson told the audience that the finest potato crop he had seen last season was raised on the above principle in a Dumfriesshire garden.

Another school of growers advocates the digging and manuring of the ground in late autumn when it is allowed to lie in ridges until spring. The surface should then be levelled and a light dresing of potato manure applied when planting.

Then there is a third method which finds favour with those gardeners who observe some system of crop rotation. Where a potato crop is to be grown on land previously occupied by cabbage, cauliflower or onion additional organic manure is unnecessary. All that is necessary is deeply to dig or trench the soil in autumn and fork in a good dressing of superphosphate in spring. It is a good plan to prepare a compost consisting of leaf-mould, well rotted turf, soot, wood ashes if they are obtainable, and a sprinkling of lime thoroughly mixed together. When the drills are taken out in April place a good layer of the compost in the bottom and after the sets are placed in position cover them with the mixture and a little of the garden soil drawn over the top. This form of treatment is well adapted for seed tubers that have been sprouted in boxes and it is also favoured by exhibitors.

Discrimination has to be observed in applying lime direct to potato ground. Experiments conducted at West Kilbride, Ayrshire, showed that a moderate use of lime had a beneficial effect on the weight of the crop, but when applied in too liberal quantities it has a tendency to produce brown scab on the skin. Although a dusting such as is indicated in the preparation of the compost can do no harm, it can be withheld if the ground was limed for the previous crop.

Plant the tubers at a depth of about 4ins. with their most promising eyes upwards, and as regards spacing 12ins. to 15ins. between the tubers and 20ins. to 24ins. between the drills represent the average distance for second early varieties, while main crop sorts need more room, which may be increased to 18ins. and 30ins. respectively.

Last year late frosts in May caused widespread injury to the potato crops, and to provide against a similar experience when growth has appeared on the surface draw the soil over the plants when low temperatures prevail.

ST. MUNGO.

FRUIT AND KITCHEN GARDEN

Apricots, Peaches and Nectarines.

Thinning Fruits—Disbudding Shoots.

THESE three kinds of stone fruits are very much appreciated by both amateur and professional cultivators. There is always something to learn by experienced growers and a great deal by the beginner. We have come to the time of year when the lovely blossom—always so cheering—is disappearing and the young fruits are to be seen nestling among the new green leaves. Now, when we have a good "set" of fruits and the trees are healthy at the same time, overcrowding of shoots and overcropping of fruits soon result if they are not attended to at the right time. It is the work of disbudding that should be attended to first. On one shoot approximately 18ins. long, in the case of the peach and the nectarine, there will be about a dozen young growths. It will not do to allow all to remain to grow on unchecked through the summer months, as they would become a tangled mass, obstruct light and air, thus preventing the wood ripening as it should do and the fruits colouring properly. Three young shoots will be enough to retain, one near the base, one near the centre and the third at the end. If the shoot is about 12ins. in length, then two young ones will be sufficient to retain, one at the base and the other near the point. In every case the shoots retained should be fore-right ones, that is, shoots growing on the upper side of the young branch and well away from the wall, if trained to a wall. The young shoots you retain now are the ones which will bear fruits next year, so maturity of wood is essential and thinly disposed shoots tend to this end. The removal of the young shoots must be done gradually, not all in one day, but a few each day for a week, at the end of which time the work of disbudding should be completed. The same principle applies in the case of thinning out the young fruits. The most prominent ones, those best placed, are the ones to retain; the ones growing underneath the branches and towards the wall are the worst placed, and all such, especially if they are undersized as compared with others, should be removed. At this thinning out quite two-thirds of the fruits that are not required to make the normal crop should be removed, the remaining one-third after the stoning stage, as there is always a risk of loss at the latter critical stage.—G. G.

Soot and Lime for Slugs and Other Pests.

THE slug (and there are many species of the slimy, creeping creature) is one of the worst of garden pests, particularly in a mild and moist season. In both vegetable plot and flower bed its possibilities for destruction are alarming at times. Soot and lime are two of the weapons the gardener wields against the slugs. Salt is also very effective. Traps are set for these pests when they are much in evidence. Bran is very attractive to them, and if little heaps are laid here and there on an open space among flowers or vegetables, the slugs may be caught and despatched. Cabbage leaves, slices of turnip, etc., will also collect a few. When it is desirable to protect a rare flower from slugs, it will be advisable to place a ring of lime (burnt shells, air-slaked) round the plant. Basic slag—and, in fact, any sort of dry powdery manure—will be found equally effective.

Salt is a powerful insecticide, but if used too freely it may damage the plants. Most gardens at some distance from the sea, if the soil is not of a damp clayey character, would benefit from a slight dressing of salt.

Lime and sand are the best for improving the physical character of wet, stiff and retentive soils. But lime will work wonders on almost any kind of garden soil (though it must not be applied to certain ornamental shrubs, especially the rhododendrons), not only in ridding it of slugs and other pests, but in the improvement of its fertility.

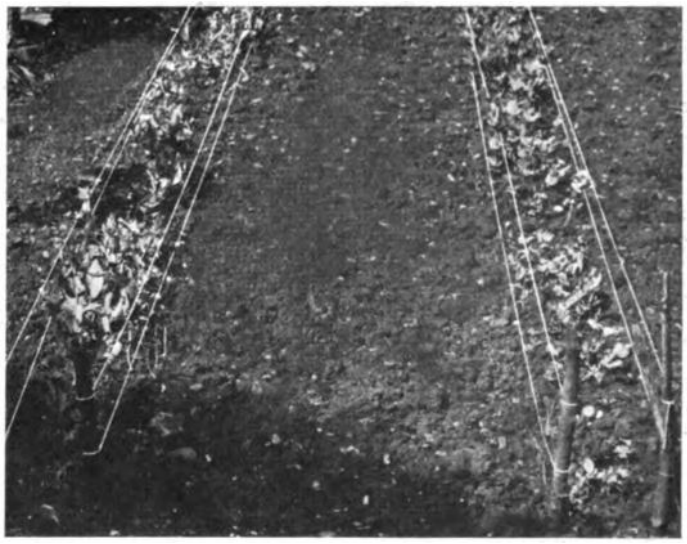
The gardener usually mixes soot and lime when applying these as remedies for

Digitized by Google

pests, because the chemical action of the lime liberates the ammonia in the soot, which gives off a pungent odour. It thus helps to disguise the scent of a crop like carrots, and the carrot fly when on her egg-laying mission, may perchance fail to locate the carrot bed. But otherwise, if the soot is being used as a manure, it should not be mixed with lime, unless it is immediately well forked into the soil.—J. W.

Novel Supports for Dwarf Peas.

GARDEN peas of a height ranging round 1ft. and 1½ft., are sown in the hope that they will be self-supporting to a great extent, although it is advisable to place small twigs on either side of the row to prevent rain and wind beating the haulm to the ground. This practice has its drawbacks. The twigs are not always easy to get, and they are a nuisance when picking the peas, as well as littering the ground with small pieces of wood.



STRING FASTENED TO STOUT STAKES MAKES USEFUL PEA SUPPORTS.

The haulm, however, must be kept from the ground, as slugs will eat both foliage and pea pods, while the latter will become very dirty if allowed to lie on the land.

A very neat and effective method of keeping the pea haulm upright from start to finish will be found in the use of string. A ball of stout string and some short stakes are required.

Drive the stakes into the ground on each side of the row at intervals of a few feet. Fasten the string to the end stake about 2ins. from the ground, and then pass it round each stake along the row, keeping the string quite taut until the other end is reached, when the string is secured to the stake there. Repeat this twice, fastening the string a couple of inches higher up the stakes each time. This will give you a three-strand fence on one side of the row of peas; and when the other side is completed similarly the peas will be growing in a string enclosure, which will prevent the haulm falling to the ground at the very start. More than this, birds do not like the string, and will not go near the peas.—H. A. D.

How to Sow Carrots.

APRIL is the best time for sowing the main crop of carrots, and any opportunity must be taken to render the soil in the best possible condition for sowing. For preference carrots should follow a crop for which the ground has been well manured, and in this case no further manuring should be necessary. If manure has to be applied, however, this should be done in early winter, when the ground is being dug or trenched.

A rich, deeply worked sandy loam is ideal for carrots; it is most important that it should be in a thoroughly well pulverised condition, otherwise good straight, unforked roots will be unobtainable.

Apply a dressing of soot to the carrot bed a short time before sowing, as this will do much to assist in preventing the unwelcome attentions of slugs and insects. Sow in drills 1in. deep and from 9ins. to 1ft. apart, according to the variety and the land.

Frequent stirring of the soil between the rows with a hoe during the growing season will keep down weeds and encourage growth.

Thinning must commence early and be done gradually, so that as many of the young roots as possible reach usable size before they are pulled out; under no circumstances, however, must they be left to interfere with the growth of those left to attain full size. When thinning, always press the loosened soil firmly back against the roots left standing, as the risk of attacks from carrot fly is then lessened.

Carrots may be injured and caused to split by autumn frosts, so that immediately the roots have attained full size they should be carefully lifted. They may be stored either in dry earth or dry sand in a frost-proof shed.

Where young and tender roots are in demand late in the season, a sowing of a stump-rooted variety should be made in June, and, if necessary, a further sowing may be made in August in a sheltered position. This latter crop will require the protection of a frame during winter. For both the June and August sowings an early variety, such as Early Horn or Nantes, should be chosen, while Altrincham, Long Red Surrey and New Intermediate are excellent for main crop purposes.—T. H.

Protecting Plants Against Late Frosts.

AT this time of the year young plants, young shoots and fruit blossom are tender and soon perish when fully exposed to a severe frost, the fruit blossom being especially liable to be destroyed if in a wet state when the frosts occur. So it is advisable to have the protecting material ready and dry, so that it can be applied at short notice. In the cold frames there will be many young plants which have been recently placed there from the other glass structures. The difference in the temperature, after sunset, will be great to that prevailing in the warm structures, and some material should be placed on the glass at sunset and removed early the following morning. The object should be to maintain the heat in the frame as high as possible while not excluding light, as daylight now is very essential to ensure sturdy young plants. Even where frames are placed on mild hotbeds for the benefit of young cucumbers, melons, dwarf beans and tender bedding-out plants, a light covering of the glass is essential. At the same time be sure that a small opening is left at the top of the frame for any rank gases to escape. The earliest potatoes on warm borders will need soil drawing up to the tops that are clear of the soil. It will be necessary to do this covering work on every alternate day as long as it is possible to cover the young haulm so.—G. G.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.
